A risk-adjusted financial measure developed by Nobel Laureate William Sharpe. It uses a fund's standard deviation and excess return to determine the reward per unit of risk. The higher a fund's Sharpe ratio, the better the fund's "risk-adjusted" performance.

See also ALPHA, BETA

Sharpe's Differential Equation

A generalization of the BESSEL DIFFERENTIAL EQUATION for functions of order 0, given by

$$zy'' + y' + (z + A)y = 0.$$

Solutions are

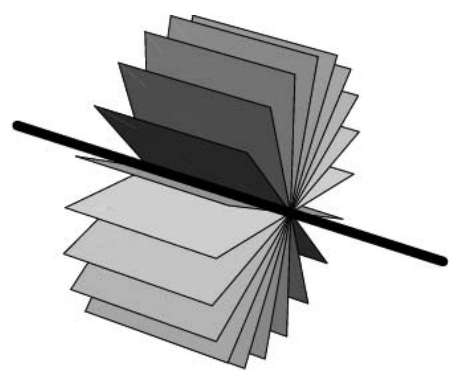
$$y = e^{\pm iz} {}_1F_1\left(\tfrac{1}{2} \mp \tfrac{1}{2} iA;\ 1;\ \mp 2iz\right).$$

where ${}_1F_1(a; b; x)$ is a CONFLUENT HYPERGEOMETRIC FUNCTION.

See also BESSEL DIFFERENTIAL EQUATION, CONFLUENT HYPERGEOMETRIC FUNCTION

Sheaf

SHEAF OF PLANES, SHEAF (TOPOLOGY)



Sheaf (Topology)

A topological GADGET related to families of ABELIAN GROUPS and MAPS.

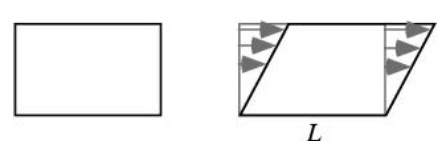
References

Iyanaga, S. and Kawada, Y. (Eds.). "Sheaves." §377 in *Encyclopedic Dictionary of Mathematics.* Cambridge, MA: MIT Press, pp. 1171–1174, 1980.

Sheaf of Planes

The set of all PLANES through a LINE. The line is sometimes called the AXIS of the sheaf, and the sheaf itself is sometimes called a pencil (Altshiller-Court 1979, p. 12).

See also LINE, PENCIL, PLANE



References

Altshiller-Court, N. *Modern Pure Solid Geometry.* New York: Chelsea, 1979.

Shear

A transformation in which all points along a given LINE L remain fixed while other points are shifted parallel to L by a distance proportional to their PERPENDICULAR distance from L. Shearing a plane figure does not change its AREA. The shear can also be generalized to 3-D, in which PLANES are translated instead of lines.

See also SHEAR FACTOR, SHEAR MATRIX

Shear Factor

The distance a point moves due to SHEAR divided by the perpendicular distance of a point from the invariant line.

See also SHEAR, SHEAR MATRIX

References

Pimentel, R. and Wall, T. *IGCSE Mathematics.* London: John Murray, p. 312, 1997.

Shear Matrix

The shear matrix e_{ij}^{s} is obtained from the IDENTITY MATRIX by inserting s at (i, j), e.g.,

$$\mathsf{e}_{12}^{s} = \begin{bmatrix} 1 & s & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}. \tag{1}$$

Bolt and Hobbs (1998) define a shear matrix as a matrix

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} \tag{2}$$

such that

$$a + b = 2 \tag{3}$$

$$ad - bc = 1. \tag{4}$$

See also ELEMENTARY MATRIX, SHEAR, SHEAR FACTOR

References

Bolt, B. and Hobbs, D. *A Mathematical Dictionary for Schools.* Cambridge, England: Cambridge University Press, 1998.

Sheffer Sequence

A sequence $s_n(x)$ is called a Sheffer sequence IFF its GENERATING FUNCTION has the form

$$\sum_{k=0}^{\infty} \frac{s_k(x)}{k!}\, t^k = A(t)e^{xB(t)}, \tag{1}$$

where

$$A(t) = A_0 + A_1 t + A_2 t^2 + \ldots \tag{2}$$

$$B(t) = B_1 t + B_2 t^2 + \ldots. \tag{3}$$

with $A_0,\ B_1 \neq 0$.

If $f(t)$ is a delta series and $g(t)$ is an invertible series, then there exists a unique sequence $s_n(x)$ of Sheffer polynomials $s_n(x)$ satisfying the orthogonality condition

$$\left\langle g(t)[f(t)]^k | s_n(x) \right\rangle = n!\delta_{nk}, \tag{4}$$

where δ_{nk} is the KRONECKER DELTA (Roman 1984, p. 17). Examples of general Sheffer sequences include the ACTUARIAL POLYNOMIALS, BERNOULLI POLYNOMIALS OF THE SECOND KIND, BOOLE POLYNOMIALS, LAGUERRE POLYNOMIALS, MEIXNER POLYNOMIALS OF THE FIRST and SECOND KINDS, POISSON-CHARLIER POLYNOMIALS, and STIRLING POLYNOMIALS.

The Sheffer sequence for $(1, f(t))$ is called the associated sequence for $f(t)$, and Roman (1984, pp. 53–86) summarizes properties of the associated Sheffer sequences and gives a number of specific examples (ABEL POLYNOMIAL, BELL POLYNOMIAL, CENTRAL FACTORIAL, EXPONENTIAL POLYNOMIAL, FALLING FACTORIAL, GOULD POLYNOMIAL, MAHLER POLYNOMIAL, MITTAG-LEFFLER POLYNOMIAL, MOTT POLYNOMIAL, POWER POLYNOMIAL). The Sheffer sequence for $(g(t),\ t)$ is called the APPELL SEQUENCE of $g(t)$, and Roman (1984, pp. 86–106) summarizes properties of Appell sequences and gives a number of specific examples.

If $s_n(x)$ is a Sheffer sequence for $(g(t),\ f(t))$, then for any polynomial $p(x)$,

$$p(x) = \sum_{k=0}^{\infty} \frac{\left\langle g(t)[f(t)]^k \mid p(x) \right\rangle}{k!}\, s_k(x). \tag{5}$$

The sequence $s_n(x)$ is Sheffer for $(g(t),\ f(t))$ IFF

$$\frac{1}{g(\bar{f}(t))}\, e^{y\bar{f}(t)} = \sum_{k=0}^{\infty} \frac{s_k(y)}{k!}\, t^k \tag{6}$$

for all y in the field C of characteristic 0, where $\bar{f}(t)$ is the compositional INVERSE FUNCTION of $f(t)$ (Roman 1984, p. 18). This formula immediately gives the GENERATING FUNCTION associated with a given Sheffer sequence.

A sequence is Sheffer for $(g(t),\ f(t))$ for some invertible $g(t)$ IFF

$$f(t)s_n(x) = ns_{n-1}(x) \tag{7}$$

for all $n \geq 0$ (Roman 1984, p. 20). The Sheffer identity states that a sequence $s_n(x)$ is Sheffer for $(g(t),\ f(t))$ for some invertible $f(t)$ IFF it satisfies some BINOMIAL-TYPE SEQUENCE

$$s_n(x+y) = \sum_{k=0}^{n} \binom{n}{k} p_k(y) s_{n-k}(x) \tag{8}$$

for all y in C, where $p_n(x)$ is associated to $f(t)$ (Roman 1984, p. 21). The RECURRENCE RELATION for Sheffer sequences is given by

$$s_{n+1}(x) = \left[x - \frac{g'(t)}{g(t)}\right] \frac{1}{f'(t)}\, s_n(x) \tag{9}$$

(Roman 1984, p. 50). A nontrivial RECURRENCE RELATION is given by

$$s_{n+1}(x) = (x - b_n)s_n(x) - d_n s_{n-1}(x) \tag{10}$$

for $s_{-1}(x) = 0,\ s_0(x) = 1,$ and $n \geq 0$ (Meixner 1934;

Sheffer 1939; Chihara 1978; Roman 1984, pp. 156–160).

The connection coefficients c_{nk} in the expression

$$s_n(x) = \sum_{k=0}^{n} c_{nk} r_k(n) \tag{11}$$

are given by

$$c_{nk} = \frac{1}{k!} \left\langle \frac{h(f^{-1}(t))}{g(f^{-1}(t))} [l(f^{-1}(t))]^k \middle| x^n \right\rangle, \tag{12}$$

where $s_n(x)$ is Sheffer for $(g(t), f(t))$ and $r_n(x)$ is Sheffer for $(h(t), l(t))$. This can also be written in terms of the polynomial of coefficients

$$t_n(x) = \sum_{k=0}^{n} c_{nk} x^k. \tag{13}$$

which is Sheffer for

$$\left(\frac{g(l^{-1}(t))}{h(l^{-1}(t))}, f(l^{-1}(t)) \right) \tag{14}$$

(Roman 1984, pp. 132–138).

A duplication formula OF THE FORM

$$r_n(ax) = \sum_{k=0}^{n} c_{nk} r_k(x) \tag{15}$$

is given by

$$c_{nk} = \frac{1}{k!} \left\langle \frac{h(al^{-1}(t))}{h(l^{-1}(t))} [l(al^{-1}(t))^k \middle| x^n \right\rangle, \tag{16}$$

where $r_n(x)$ is Sheffer for $(h(t), l(t))$ (Roman 1984, pp. 132–138).

Sheffer Stroke

NAND

Shephard's Problem

Measurements of a centered convex body in Euclidean n-space (for $n \geq 3$) show that its brightness function (the volume of each projection) is smaller than that of another such body. Is it true that its VOLUME is also smaller? C. M. Petty and R. Schneider showed in 1967 that the answer is yes if the body with the larger brightness function is a projection body, but no in general for every n.

Sheppard's Correction

A correction which must be applied to the measured MOMENTS m_k obtained from NORMALLY DISTRIBUTED data which have been BINNED in order to obtain correct estimators $\hat{\mu}_i$ for the population moments μ_i. The corrected versions of the second, third, and fourth moments are then

$$\hat{\mu}_2 = m_2 - \tfrac{1}{12} c^2 \tag{1}$$

$$\hat{\mu}_3 = m_3 \tag{2}$$

$$\hat{\mu}_4 = m_4 - \tfrac{1}{2} m_2 + \tfrac{7}{240} c^2, \tag{3}$$

where c is the CLASS INTERVAL.

If κ_r' is the rth CUMULANT of an ungrouped distribution and κ_r the rth CUMULANT of the grouped distribution with CLASS INTERVAL c, the corrected cumulants (under rather restrictive conditions) are

$$\kappa_r' = \begin{cases} \kappa_r & \text{for r odd} \\ \kappa_r - \dfrac{B_r}{r} c^r & \text{for r even,} \end{cases} \tag{4}$$

where B_r is the rth BERNOULLI NUMBER, giving

$$\kappa_1' = \kappa_1 \tag{5}$$

$$\kappa_2' = \kappa_2 - \tfrac{1}{12} c^2 \tag{6}$$

$$\kappa_3' = \kappa_3 \tag{7}$$

$$\kappa_4' = \kappa_4 + \tfrac{1}{120} c^4 \tag{8}$$

$$\kappa_5' = \kappa_5 \tag{9}$$

$$\kappa_6' = \kappa_6 - \tfrac{1}{252} c^6. \tag{10}$$

For a proof, see Kendall *et al.* (1987).

Sherman-Morrison Formula

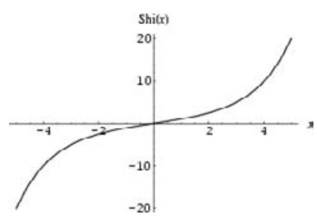
A formula which allows a perturbed MATRIX to be computed for a small change to a given MATRIX A. If the change can be written in the form

$$\mathbf{u} \otimes \mathbf{v}$$

for two vectors **u** and **v**, then the Sherman-Morrison formula is

$$(\mathsf{A} + \mathbf{u} \otimes \mathbf{v})^{-1} = \mathsf{A}^{-1} - \frac{(\mathsf{A}^{-1}\mathbf{u}) \otimes (\mathbf{v} \cdot \mathsf{A}^{-1})}{1 + \lambda},$$

where



$$\lambda \equiv \mathbf{v} \cdot \mathsf{A}^{-1}\mathbf{u}.$$

Shidlovskii Theorem

Let $f_1(z)$, ..., $f_m(z)$ for $m \geq 1$ be a set of E-FUNCTIONS that (1) form a solution of the system of differential equations

$$y'_k = q_{k0} + \sum_{j=1}^{m} q_{kj} y_j$$

for $q_{kj} \in \mathbb{C}(z)$ and $k = 1, ..., m$ and (2) are ALGEBRAICALLY INDEPENDENT over $\mathbb{C}(z)$. Then for all $\alpha \in \mathbb{A}$, where $\mathbb{A}$ denotes the set of ALGEBRAIC NUMBERS with $\alpha \neq 0$ and distinct from singularities of the differential equations, the numbers $f_1(\alpha)$, ..., $f_m(\alpha)$ are ALGEBRAICALLY INDEPENDENT (Nesterenko 1999).

Shoemaker's Knife

ARBELOS

Short Exact Sequence

A short exact sequence of groups A, B, and C is given by two maps $\alpha : A \to B$ and $\beta : B \to C$ and is written

$$0 \to A \to B \to C \to 0.$$

Because it is an EXACT SEQUENCE, α is INJECTIVE, and β is SURJECTIVE. Moreover, the KERNEL of β is the image of α. Hence, the group A can be considered as a (normal) subgroup of B, and C is isomorphic to B/A.

A short exact sequence is said to split if there is a map $\gamma : C \to B$ such that $\beta \circ \gamma$ is the identity on C. This only happens when B is the DIRECT PRODUCT of A and C.

The notion of a short exact sequence also makes sense for MODULES and SHEAVES.

Shuffle

The randomization of a deck of CARDS by repeated interleaving. More generally, a shuffle is a rearrangement of the elements in an ordered list. Shuffling by exactly interleaving two halves of a deck is called a RIFFLE SHUFFLE. Normal shuffling leaves gaps of different lengths between the two layers of cards and so randomizes the order of the cards.

A deck of 52 CARDS must be shuffled seven times for it to be randomized (Aldous and Diaconis 1986, Bayer and Diaconis 1992). This is intermediate between too few shuffles and the decreasing effectiveness of many shuffles. One of Bayer and Diaconis's randomness CRITERIA, however, gives $3 \lg k/2$ shuffles for a k-card deck, yielding 11–12 shuffles for 52 CARDS. Amazingly, if a deck of n cards is shuffled by successively exchanging the cards in position 1, 2, ..., n with cards in randomly chosen positions (a so-called EXCHANGE SHUFFLE), then for $n \geq 18$, the identity permutation (i.e., the original state before the cards were shuffled) is the most likely (Goldstine and Moews 2000).

Keller (1995) shows that roughly $\ln k$ shuffles are needed just to randomize the bottom card.

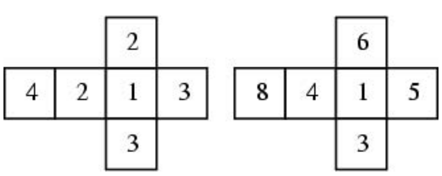
Siamese Dodecahedron

SNUB DISPHENOID

Siamese Method

A method for constructing MAGIC SQUARES of ODD order, also called DE LA LOUBERE'S METHOD.

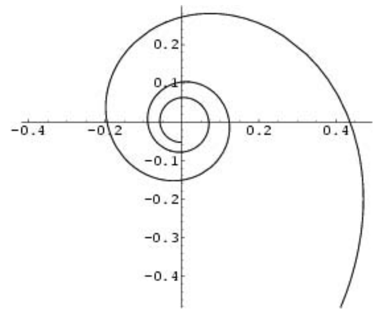


See also MAGIC SQUARE

Sibling

Two nodes connected to the same node which are same distance from the ROOT NODE in a ROOTED TREE are called siblings.

See also CHILD, ROOT NODE, ROOTED TREE, TREE



Sicherman Dice

A pair of DICE which have the same ODDS for throwing every number as a normal pair of 6-sided DICE. They are the only such alternate arrangement if face values are required to be positive. However, if faces are permitted to have zero value (i.e., to be blank), then two additional possible equal-odds pairs of dice are obtained by subtracting one from each face on either of the two dice and adding one to each face the other. If negative values are permitted, there are an infinite number of equal-odds dice.

See also DICE, EFRON'S DICE

Sici Spiral

The spiral

$$x = c\ \mathrm{ci}(t)$$

$$y = c\left[\mathrm{si}(t) - \tfrac{1}{2}\pi\right).$$

where ci(t) and si(t) are the COSINE INTEGRAL and SINE INTEGRAL, respectively, and c is a constant.

Siegel Modular Function

SIEGEL THETA FUNCTION

Siegel Theta Function

A Γ_n-invariant meromorphic function on the space of all $p \times p$ symmetric COMPLEX MATRICES $Z = X + iY$ with positive definite IMAGINARY PART. It is defined by

$$\Theta(Z, \mathbf{s}) = \sum_{\mathbf{t}} e^{\pi i \mathbf{t}^T Z \mathbf{t} + 2\pi i \mathbf{t}^T \mathbf{s}},$$

where **s** is a complex p-vector, **t** is an integer p-vector that ranges over the entire p-D lattice of integers, and A^T denotes a matrix (or vector) transpose.

This function was investigated by many of the luminaries of nineteenth century mathematics, Riemann , Weierstrass , Frobenius , Poincaré. Umemura has expressed the ROOTS of an arbitrary POLYNOMIAL in terms of Siegel theta functions (Mumford 1984). The Siegel theta functions is implemented in *Mathematica* as `SiegelTheta` in the *Mathematica* add-on package `NumberTheory`SiegelTheta`` (which can be loaded with the command `< <NumberTheory``).

Siegel's Paradox

If a fixed FRACTION x of a given amount of money P is lost, and then the same FRACTION x of the remaining amount is gained, the result is less than the original and equal to the final amount if a FRACTION x is first gained, then lost. This can easily be seen from the fact that

$$[P(1-x)](1+x) = P(1-x^2) < P$$

$$[P(1+x)](1-x) = P(1-x^2) < P.$$

Siegel's Theorem

There are at least two Siegel's theorems. The first states that an ELLIPTIC CURVE can have only a finite number of points with INTEGER coordinates.

The second states that if ξ is an ALGEBRAIC NUMBER of degree r, then there is an $A(\xi)$ depending only on ξ such that

$$\left|\xi - \frac{p}{q}\right| > \frac{A(\xi)}{q^{2r^{1/2}}}$$

for all integer p and q (Landau 1970, pp. 37–56; Hardy 1999, p. 79).

Sierpinski Carpet

A FRACTAL which is constructed analogously to the SIERPINSKI SIEVE, but using squares instead of triangles. Let N_n be the number of black boxes, L_n the length of a side of a white box, and A_n the fractional

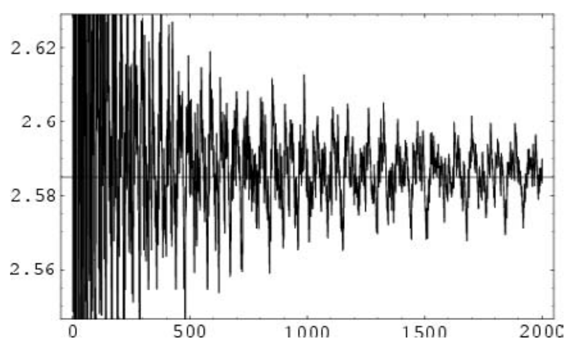
AREA of black boxes after the nth iteration. Then

$$N_n = 8^n \quad (1)$$

$$L_n = (\tfrac{1}{3})^n = 3^{-n} \quad (2)$$

$$A_n = L_n^2 N_n = (\tfrac{8}{9})^n. \quad (3)$$

The CAPACITY DIMENSION is therefore



$$d_{\text{cap}} = -\lim_{n\to\infty} \frac{\ln N_n}{\ln L_n} = -\lim_{n\to\infty} \frac{\ln(8^n)}{\ln(3^{-n})} = \frac{\ln 8}{\ln 3} = \frac{3 \ln 2}{\ln 3}$$
$$= 1.892789260\ldots. \quad (4)$$

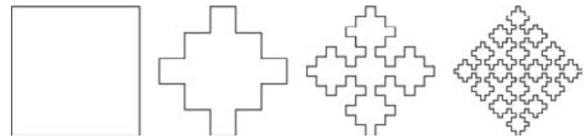
Sierpiński Constant

Let the SUM OF SQUARES FUNCTION $r_k(n)$ denote the number of representations of n by k squares, then the SUMMATORY FUNCTION of $r_2(k)/k$ has the ASYMPTOTIC expansion

$$\sum_{k=1}^{n} \frac{r_2(k)}{k} = K + \pi \ln n + \mathcal{O}(n^{-1/2}),$$

where $K = 2.5849817596$ is the Sierpinski constant. The above plot shows

$$\left[\sum_{k=1}^{n} \frac{r_2(k)}{k}\right] - \pi \ln n,$$



with the value of K indicated as the solid horizontal line.

See also SUM OF SQUARES FUNCTION

Sierpinski Curve

There are several FRACTAL curves associated with Sierpinski. The above curve is one example, and the SIERPINSKI ARROWHEAD CURVE is another. The limit of the curve illustrated above has AREA

$$A = \tfrac{5}{12}.$$

The AREA for a related curve due to Sierpinski (1912) illustrated above is

$$A = \tfrac{1}{3}(7 - 4\sqrt{2}).$$

(Steinhaus 1983, pp. 102–103; Cundy and Rollett 1989; Wells 1991, p. 229).

Sierpinski Gasket

SIERPINSKI SIEVE

Sierpinski Number of the First Kind

Numbers OF THE FORM $S_n \equiv n^n + 1$. The first few are 2, 5, 28, 257, 3126, 46657, 823544, 16777217, ... (Sloane's A014566). Sierpinski proved that if S_n is

PRIME with $n \geq 2$, then $S_n = F_{m+2^m}$, where F_m is a FERMAT NUMBER with $m \geq 0$. The first few such numbers are $F_1 = 5$, $F_3 = 257$, F_6, F_{11}, F_{20}, and F_{37}. Of these, 5 and 257 are PRIME, and the first unknown case is $F_{37} > 10^{3\times 10^{10}}$.

See also CULLEN NUMBER, CUNNINGHAM NUMBER, FERMAT NUMBER, WOODALL NUMBER

Sierpiński Number of the Second Kind

A number k satisfying SIERPINSKI'S COMPOSITE NUMBER THEOREM, i.e., such that $k \cdot 2^n + 1$ is COMPOSITE for every $n \geq 1$. The smallest known is $k = 78,557$, but there remain 35 smaller candidates (the smallest of which is 4847) which are known to generate only composite numbers for $n \leq 18,000$ or more (Ribenboim 1996, p. 358).

Let $a(k)$ be smallest n for which $(2k-1)\cdot 2^n + 1$ is PRIME, then the first few values are 0, 1, 1, 2, 1, 1, 2, 1, 3, 6, 1, 1, 2, 2, 1, 8, 1, 1, 2, 1, 1, 2, 2, 583, ... (Sloane's A046067). The second smallest n are given by 1, 2, 3, 4, 2, 3, 8, 2, 15, 10, 4, 9, 4, 4, 3, 60, 6, 3, 4, 2, 11, 6, 9, 1483, ... (Sloane's A046068). Quite large n can be required to obtain the first prime even for small k. For example, the smallest prime OF THE FORM $383 \cdot 2^n + 1$ is $383 \cdot 2^{6393} + 1$. There are an infinite number of Sierpinski numbers which are PRIME.

The smallest odd k such that $k + 2^n$ is COMPOSITE for all $n < k$ are 773, 2131, 2491, 4471, 5101, ...

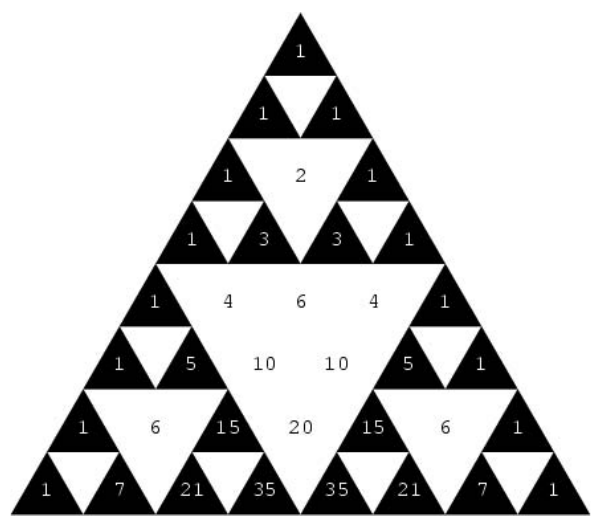
Sierpinski Sieve

A FRACTAL described by Sierpinski in 1915. It is also called the SIERPINSKI GASKET or SIERPINSKI TRIANGLE. The curve can be written as a LINDENMAYER SYSTEM with initial string "FXF-FF-FF", STRING REWRITING rules "F" -> "FF", "X" -> "--FXF++FXF++FXF--", and angle 60°.

Let N_n be the number of black triangles after iteration n, L_n the length of a side of a triangle, and A_n the fractional AREA which is black after the nth iteration. Then

$$N_n = 3^n \tag{1}$$



$$L_n = \left(\tfrac{1}{2}\right)^n = 2^{-n} \tag{2}$$

$$A_n = L_n^2 N_n = \left(\tfrac{3}{4}\right)^n. \tag{3}$$

The CAPACITY DIMENSION is therefore

$$d_{\text{cap}} = -\lim_{n\to\infty} \frac{\ln N_n}{\ln L_n} = -\lim_{n\to\infty} \frac{\ln(3^n)}{\ln(2^{-n})} = \frac{\ln 3}{\ln 2}$$

$$= 1.584962500\ldots. \tag{4}$$

In PASCAL'S TRIANGLE, coloring all ODD numbers black and EVEN numbers white produces a Sierpinski sieve (Guy 1990).

Sierpinski's Composite Number Theorem
There exist infinitely many ODD INTEGERS k such that $k \cdot 2^n + 1$ is COMPOSITE for every $n \geq 1$. Numbers k with this property are called SIERPINSKI NUMBERS OF THE SECOND KIND, and analogous numbers with the plus sign replaced by a minus are called RIESEL NUMBERS. it is conjectured that the smallest SIERPINSKI NUMBER OF THE SECOND KIND is $k = 78,557$ and the smallest RIESEL NUMBER is $k = 509,203$.

Sierpinski's Theorem
SIERPINSKI'S COMPOSITE NUMBER THEOREM, SIERPINSKI'S PRIME SEQUENCE THEOREM

Sieve

A process of successively crossing out members of a list according to a set of rules such that only some remain. The best known sieve is the ERATOSTHENES SIEVE for generating PRIME NUMBERS. In fact, numbers generated by sieves seem to share a surprisingly large number of properties with the PRIME NUMBERS.

Sieve Formula

INCLUSION-EXCLUSION PRINCIPLE

Sieve of Eratosthenes

An ALGORITHM for making tables of PRIMES. Sequentially write down the INTEGERS from 2 to the highest number n you wish to include in the table. Cross out all numbers >2 which are divisible by 2 (every second number). Find the smallest remaining number >2. It is 3. So cross out all numbers >3 which are divisible by 3 (every third number). Find the smallest remaining number >3. It is 5. So cross out all numbers >5 which are divisible by 5 (every fifth number).

Continue until you have crossed out all numbers divisible by $\lfloor\sqrt{n}\rfloor$, where $\lfloor x\rfloor$ is the FLOOR FUNCTION. The numbers remaining are PRIME. This procedure is illustrated in the above diagram which sieves up to 50, and therefore crosses out PRIMES up to $\lfloor\sqrt{50}\rfloor=7$. If the procedure is then continued up to n, then the number of cross-outs gives the number of distinct PRIME FACTORS of each number.

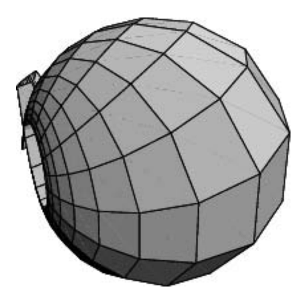
Sievert Integral



The integral

$$\int_0^\theta e^{-x \sec \phi}\, d\phi.$$

References

Abramowitz, M. and Stegun, C. A. (Eds.). "Sievert Integral." §27.4 in *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables, 9th printing.* New York: Dover, pp. 1000–1001, 1972.

Sievert's Surface

A constant-curvature surface which can be given parametrically by

$$x = r\cos\phi \tag{1}$$

$$y = r\sin\phi \tag{2}$$

$$z = \frac{\ln\left[\tan\left(\frac{1}{2}v\right)\right] + a(C+1)\cos v}{\sqrt{C}}, \tag{3}$$

where

$$\phi \equiv -\frac{u}{\sqrt{C+1}} + \tan^{-1}\left(\tan u\,\sqrt{C+1}\right) \quad (4)$$

$$a \equiv \frac{2}{C + 1 - C\sin^2 v \cos^2 u} \quad (5)$$

$$r \equiv \frac{a\sqrt{(C+1)(1+C\sin^2 u)}\sin v}{\sqrt{C}}, \quad (6)$$

with $|u| < \pi/2$ and $0 < v < \pi$ (Reckziegel 1986).

The coefficients of the FIRST FUNDAMENTAL FORM are

$$E = \frac{64a\cos^2 u\cos^2 v}{[4 + 3a - a\cos(2u) + 2a\cos^2 u\cos^2(2v)]^2} \quad (7)$$

$$F = 0 \quad (8)$$

$$G = \frac{64[(1+a)\csc v + a\cos^2 u\sin v]^2}{4a[4 + 3a - a\cos(2u) + 2a\cos^2 u\cos^2(2v)]^2}, \quad (9)$$

and the coefficients of the SECOND FUNDAMENTAL FORM are

$$e = \sqrt{\frac{a}{a+1}} \times \frac{8a\cos^3 u\sin(3v) - 4\cos u[8 + 11a + 3a\cos(2u)]}{[4 + 3a - a\cos(2u) + 2a\cos^2 u\cos^2(2v)]^2} \quad (10)$$

$$f = 0 \quad (11)$$

$$g = \sqrt{\frac{a+1}{a}} \times \frac{[4 + 5a + a\cos(2u) - 2a\cos^2 u\cos(2v)]\csc\left(\tfrac{1}{2}v\right)\sec\left(\tfrac{1}{2}v\right)}{[4 + 3a - a\cos(2u) + 2a\cos^2 u\cos^2(2v)]^2}. \quad (12)$$

The Sievert surface has GAUSSIAN and MEAN CURVATURES given by

$$K = 1 \quad (13)$$

$$H = \frac{1}{1 + (a+1)\tan^2 u}. \quad (14)$$

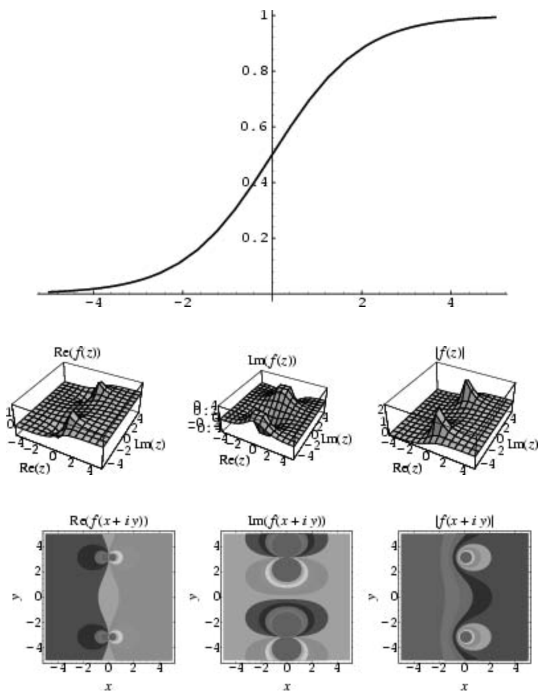
Sigma Algebra

Let X be a SET. Then a σ-algebra F is a nonempty collection of SUBSETS of X such that the following hold:

1. The EMPTY SET is in F.
2. If A is in F, then so is the complement of A.
3. If A_n is a SEQUENCE of elements of F, then the UNION of the A_ns is in F.

If S is any collection of subsets of X, then we can always find a σ-algebra containing S, namely the POWER SET of X. By taking the INTERSECTION of all σ-algebras containing S, we obtain the smallest such σ-algebra. We call the smallest σ-algebra containing S the σ-algebra generated by S.

See also BOREL SIGMA ALGEBRA, BOREL SPACE, MEASURABLE SET, MEASURABLE SPACE, MEASURE ALGEBRA, STANDARD SPACE



Sigma Function

DIVISOR FUNCTION

Sigmoid Curve

SIGMOID FUNCTION

Sigmoid Function

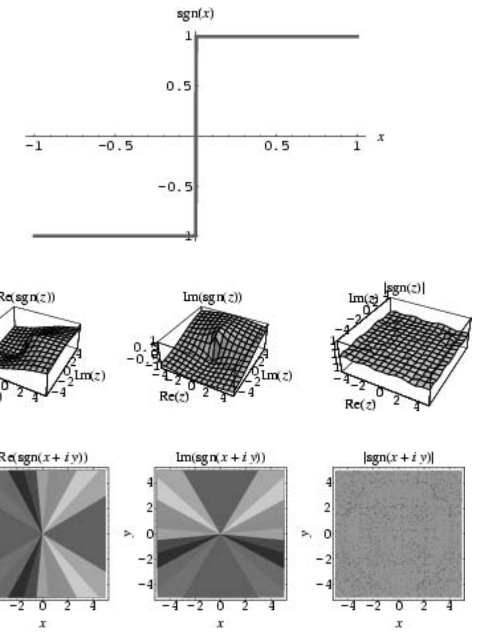
The function

$$y = \frac{1}{1 + e^{-x}}$$

which is the solution to the ORDINARY DIFFERENTIAL EQUATION

$$\frac{dy}{dx} = y(1 - y).$$

It has an inflection point at $x = 0$, where



$$y''(x) = -\frac{e^x(e^x - 1)}{(e^x - 1)^3} = 0.$$

Sign

The sign of a number, also called SGN, is -1 for a NEGATIVE number (i.e., one with a MINUS SIGN "–"), 0 for the number ZERO, or $+1$ for a POSITIVE number (i.e., one with a PLUS SIGN "+").

See also ABSOLUTE VALUE, MINUS SIGN, NEGATIVE, PLUS SIGN, POSITIVE, SGN, ZERO

Signalizer Functor Theorem

$$\Theta(G;\ A) = \langle \theta(a) : a \in A - 1 \rangle$$

is an A-invariant solvable p'-subgroup of G.

Signature

PERMUTATION SYMBOL, SIGNATURE (KNOT), SIGNATURE (MATRIX), SIGNATURE (NUMBER FIELD), SIGNATURE (QUADRATIC FORM), SIGNATURE (RECURRENCE RELATION), SIGNATURE SEQUENCE

Signature (Knot)

The signature $s(K)$ of a KNOT K can be defined using the SKEIN RELATIONSHIP

$$s(\text{unknot}) = 0$$

$$s(K_+) - s(K_-) \in \{0,\ 2\},$$

and

$$4 | s(K) \leftrightarrow \nabla(K)(2i) > 0,$$

where $\nabla(K)$ is the ALEXANDER-CONWAY POLYNOMIAL and $\nabla(K)(2i)$ is an ODD NUMBER.

Many UNKNOTTING NUMBERS can be determined using a knot's signature.

See also SKEIN RELATIONSHIP, UNKNOTTING NUMBER

Signature (Matrix)

A real, nondegenerate $n \times n$ SYMMETRIC MATRIX A, and its corresponding SYMMETRIC BILINEAR FORM $Q(v, w) = v^{\mathrm{T}}\mathsf{A}w$, has signature (p, q) if there is a nondegenerate matrix C such that $\mathsf{C}^{\mathrm{T}}\mathsf{AC}$ is a diagonal matrix with p 1s and q -1s. In this case, $Q(\mathsf{C}v, \mathsf{C}w)$ is a DIAGONAL QUADRATIC FORM. For example,

$$\mathsf{A} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix}$$

gives a SYMMETRIC BILINEAR FORM Q called the LORENTZIAN INNER PRODUCT, which has signature (3, 1). The following *Mathematica* function returns the signature of a SYMMETRIC MATRIX as a list of three elements, corresponding to 1s, 0s, and -1s.

```
SignatureMatrix[a_List?MatrixQ] := Module[
   {
    q, ctr, diag, t2, signplus, signminus,
   v1 = Prepend[Table[0, {Length[a] - 1}], 1]
   },
   q[v_] := v.a.v;
      If[(t2 = q[v1]) != 0, v1 /=
Sqrt[Abs[t2]]];
   ctr = {v1};
   Do[
    v1 = NullSpace[ctr.a][[1]];
       If[(t2 = q[v1]) != 0, v1 /=
Sqrt[Abs[t2]]];
    AppendTo[ctr, v1],
    {Length[a] - 1}
   ];
   diag = ctr.a.Transpose[ctr];
   signplus = Count[diag, 1, 2];
   signminus = Count[diag, -1, 2];
  {signplus, Length[a] - signplus - signminus,
signminus}
  ]
```

Gradshteyn, I. S. and Ryzhik, I. M. *Tables of Integrals, Series, and Products, 6th ed.* San Diego, CA: Academic Press, p. 1105, 2000.

Signature (Recurrence Relation)

Let a sequence be defined by

$$A_{-1} = s$$

$$A_0 = 3$$

$$A_1 = r$$

$$A_n = rA_{n-1} - sA_{n-2} + A_{n-3}.$$

Also define the associated POLYNOMIAL

$$f(x) = x^3 - rx^2 + sx + 1,$$

and let Δ be its discriminant. The PERRIN SEQUENCE is a special case corresponding to $A_n(0, -1)$. The signature mod m of an INTEGER n with respect to the sequence $A_k(r, s)$ is then defined as the 6-tuple $(A_{-n-1}, A_{-n}, A_{-n+1}, A_{n-1}, A_n, A_{n+1})$ (mod m).

1. An INTEGER n has an S-signature if its signature (mod n) is $(A_{-2}, A_{-1}, A_0, A_1, A_2)$.
2. An INTEGER n has a Q-signature if its signature (mod n) is CONGRUENT to (A, s, B, B, r, C) where, for some INTEGER a with $f(a) \equiv 0 (\text{mod } n)$, $A \equiv a^{-2} + 2a$, $B \equiv -ra^2 + (r^2 - s)a$, and $C \equiv a^2 + 2a^{-1}$.
3. An INTEGER n has an I-signature if its signature (mod n) is CONGRUENT to (r, s, D', D, r, s), where $D' + D \equiv rs - 3$ and $(D' + D) \equiv \Delta$.

Signature Sequence

Let θ be an IRRATIONAL NUMBER, define $S(\theta) = \{c + d\theta : c, d \in \mathbb{N}\}$, and let $c_n(\theta) + d_n\theta(\theta)$ be the sequence obtained by arranging the elements of $S(\theta)$ in increasing order. A sequence x is said to be a signature sequence if there EXISTS a POSITIVE IRRATIONAL NUMBER θ such that $x = \{(c_n\theta)\}$, and x is called the signature of θ.

The signature of an IRRATIONAL NUMBER is a FRACTAL SEQUENCE. Also, if x is a signature sequence, then the LOWER-TRIMMED SUBSEQUENCE is $V(x) = x$.

Signed Deviation

The signed deviation is defined by

$$\Delta u_i \equiv (u_i - \bar{u}),$$

so the average deviation is

$$\overline{\Delta u} = \overline{u_i - u} = \overline{u_i} - \bar{u} = 0.$$

See also ABSOLUTE DEVIATION, DEVIATION, DISPERSION (STATISTICS), MEAN DEVIATION, QUARTILE DEVIATION, STANDARD DEVIATION, VARIANCE

Significance

Let $\delta \equiv z \le z_{\text{observed}}$. A value $0 \le \alpha \le 1$ such that $P(\delta) \le \alpha$ is considered "significant" (i.e., is not simply due to chance) is known as an ALPHA VALUE. The PROBABILITY that a variate would assume a value greater than or equal to the observed value strictly by chance, $P(\delta)$, is known as a P-VALUE.

Depending on the type of data and conventional practices of a given field of study, a variety of different alpha values may be used. One commonly used terminology takes $P(\delta) \ge 5\%$ as "not significant," $1\% < P(\delta) < 5\%$, as "significant" (sometimes denoted *), and $P(\delta) < 1\%$ as "highly significant" (sometimes denoted **). Some authors use the term "almost significant" to refer to $5\% < P(\delta) < 10\%$, although this practice is not recommended.

See also ALPHA VALUE, COINCIDENCE, CONFIDENCE INTERVAL, P-VALUE, PROBABLE ERROR, SIGNIFICANCE TEST, STATISTICAL TEST

Significance Test

A test for determining the probability that a given result could not have occurred by chance (its SIGNIFICANCE).

See also SIGNIFICANCE, STATISTICAL TEST

Significant Digits

When a number is expressed in SCIENTIFIC NOTATION, the number of significant figures is the number of DIGITS needed to express the number to within the uncertainty of measurement. For example, if a quantity had been measured to be 1.234 $\pm$ 0.002, four figures would be significant. No more figures should be given than are allowed by the uncertainty. For example, a quantity written as 1.234 $\pm$ 0.1 is incorrect; it should really be written as 1.2 $\pm$ 0.1.

The number of significant figures of a MULTIPLICATION or DIVISION of two or more quantities is equal to the smallest number of significant figures for the quantities involved. For ADDITION or SUBTRACTION, the number of significant figures is determined with the smallest significant figure of all the quantities involved. For example, the sum $10.234 + 5.2 + 100.3234$ is 115.7574, but should be written 115.8 (with rounding), since the quantity 5.2 is significant only to $\pm$ 0.1.

Similar

Two figures are said to be similar when all corresponding ANGLES are equal. Two figures are DIRECTLY SIMILAR when all corresponding ANGLES are equal and described in the same rotational sense. This relationship is written $A \sim B$. (The symbol $\sim$ is also used to mean "is the same order of magnitude as" and "is ASYMPTOTIC to.") Two figures are INVERSELY SIMILAR when all corresponding ANGLES are equal and described in the opposite rotational sense.

Similar Matrices

Two SQUARE MATRICES A and B that are related by

$$\mathsf{B} = \mathsf{X}^{-1}\mathsf{A}\mathsf{X}, \qquad (1)$$

where X is a square NONSINGULAR MATRIX are said to be similar. A transformation of the form $\mathsf{X}^{-1}\mathsf{A}\mathsf{X}$ is called a SIMILARITY TRANSFORMATION, or conjugation by X. For example,

$$\begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \qquad (2)$$

and

$$\begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} \qquad (3)$$

are similar under conjugation by

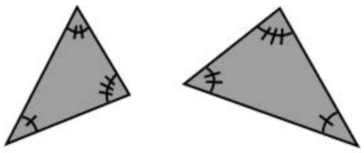
$$\mathsf{C} = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}. \qquad (4)$$

Similar matrices represent the same LINEAR TRANSFORMATION after a change of basis (for the domain and range simultaneously). Recall that a matrix corresponds to a LINEAR TRANSFORMATION, and a LINEAR TRANSFORMATION corresponds to a matrix after choosing a basis b_i,

$$T\left(\sum \lambda_i b_i\right) = \sum a_{ji}\lambda_i b_j \qquad (5)$$

Changing the basis changes the coefficients of the matrix,

$$T\left(\sum \gamma_i e_i\right) = \sum a'_{ji}\gamma_i e_j \qquad (6)$$



If $T(v) = Av$ uses the standard basis vectors, then T is the matrix CAC^{-1} using the basis vectors $b_i = Ce_i$.

Similar Triangles

similar triangles

Two triangles are similar if their triples of vertex angles are the same.

See also DIRECTLY SIMILAR, INVERSELY SIMILAR, SIMILAR

Similarity Axis

D'ALEMBERT'S THEOREM

Similarity Dimension

To multiply the size of a d-D object by a factor a, $c \equiv a^d$ copies are required, and the quantity

$$d = \frac{\ln c}{\ln a}$$

is called the similarity dimension.

Similarity Point

External (or positive) and internal (or negative) similarity points of two CIRCLES with centers C and C' and RADII r and r' are the points E and I on the lines CC' such that

$$\frac{CE}{C'E} = \frac{r}{r'},$$

or

$$\frac{CI}{C'I} = -\frac{r}{r'}.$$

See also D'ALEMBERT'S THEOREM

Similarity Transformation

An ANGLE-preserving transformation. A similarity transformation has a transformation matrix A' of the form

$$\mathsf{A}' \equiv \mathsf{B}\mathsf{A}\mathsf{B}^{-1}, \qquad (1)$$

where A and B are known as SIMILAR MATRICES (Golub and van Loan 1996, p. 311).

If A is an ANTISYMMETRIC MATRIX ($a_{ij} = -a_{ji}$) and B is an ORTHOGONAL MATRIX, then

$$(bab^{-1})_{ij} = b_{ik}a_{kl}b_{lj}^{-1} = -b_{ik}a_{lk}b_{lj}^{-1}$$
$$= -b_{ki}^{\dagger}a_{lk}(b^{\dagger})_{jl}^{-1} = -b_{ki}^{-1}a_{ki}b_{jl} = b_{jl}a_{lk}b_{ki}^{-1}$$
$$= -(bab^{-1})_{ji}. \quad (2)$$

The DETERMINANT of the similarity transformation of a MATRIX is equal to the determinant of the original MATRIX

$$|BAB^{-1}| = |B||A||B^{-1}| = |B||A|\frac{1}{|B|} = |A|. \quad (3)$$

The determinant of a similarity transformation minus a multiple of the unit MATRIX is given by

$$|B^{-1}AB - \lambda I| = |B^{-1}AB - B^{-1}\lambda IB| = |B^{-1}(A - \lambda I)B|$$
$$= |B^{-1}||A - \lambda I||B| = |A - \lambda I|. \quad (4)$$

Similarity transformations and the concept of SELF-SIMILARITY are important foundations of FRACTALS and ITERATED FUNCTION SYSTEMS.

See also CONFORMAL MAPPING, DETERMINANT, DILATION, ITERATED FUNCTION SYSTEM, SIMILAR MATRICES

Similitude Center

Also called a self-homologous point. If two SIMILAR figures lie in the plane but do not have parallel sides (they are not HOMOTHETIC), there exists a center of similitude which occupies the same homologous position with respect to the two figures. The LOCUS of similitude centers of two nonconcentric circles is another circle having the line joining the two homothetic centers as its DIAMETER.

There are a number of interesting theorems regarding three CIRCLES (Johnson 1929, pp. 151–152).

1. The external similitude centers of three circles are COLLINEAR.
2. Any two internal similitude centers are COLLINEAR with the third external one.
3. If the center of each circle is connected with the internal similitude center of the other three [sic], the connectors are CONCURRENT.
4. If one center is connected with the internal similitude center of the other two, the others with the corresponding external centers, the connectors are CONCURRENT.

The six centers of similitude of three circles taken by pairs are the vertices of a COMPLETE QUADRILATERAL (Evelyn *et al.* 1974, pp. 21–22).

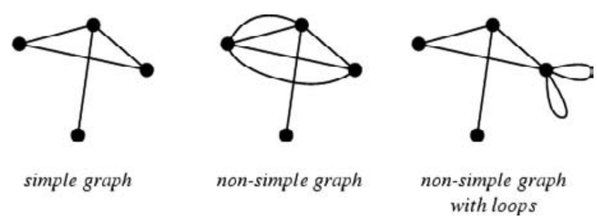
Krantz, S. G. "Closed Curves." §2.1.2 in *Handbook of Complex Analysis.* Boston, MA: Birkhäuser, pp. 19–20, 1999.

Simple Double Point

ORDINARY DOUBLE POINT



Simple Function

A simple function is a finite sum $\Sigma_i\ a_i \chi A_i$, where the functions χA_i are CHARACTERISTIC FUNCTIONS on a set A. Another description of a simple function is a function that takes on finitely many values in its range.

The collection of simple functions is CLOSED under addition and multiplication. In addition, it is easy to integrate a simple function. By approximating a given function f by simple functions, the LEBESGUE INTEGRAL of f can be calculated.

See also CHARACTERISTIC FUNCTION (SET), LEBESGUE INTEGRAL, SET

Simple Graph

A GRAPH for which at most one EDGE connects any two nodes. Unless stated otherwise, the unqualified term "graph" usually refers to a *simple* graph. A nonsimple graph with no loops but which can contain more than one edge between any two points is called a MULTIGRAPH.

See also ADJACENCY MATRIX, EDGE (GRAPH), GRAPH, MULTIGRAPH, REGULAR GRAPH, STEINITZ'S THEOREM

References
Skiena, S. *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, p. 89, 1990.

Steinbach, P. *Field Guide to Simple Graphs.* Albuquerque, NM: Design Lab, 1990.

Simple Group

A simple group is a GROUP whose NORMAL SUBGROUPS (INVARIANT SUBGROUPS) are ORDER one or the whole of the original GROUP. Simple groups include ALTERNATING GROUPS, CYCLIC GROUPS, LIE-TYPE GROUPS (five varieties), and SPORADIC GROUPS (26 varieties, including the MONSTER GROUP). The CLASSIFICATION THEOREM of finite simple groups states that such groups can be classified completely into the five types:

1. CYCLIC GROUPS of PRIME ORDER,
2. ALTERNATING GROUPS of degree at least five
3. LIE-TYPE CHEVALLEY GROUPS,
4. LIE-TYPE (TWISTED CHEVALLEY GROUPS or the TITS GROUP), and
5. SPORADIC GROUPS.

BURNSIDE'S CONJECTURE states that every non-ABELIAN SIMPLE GROUP has EVEN ORDER.

See also ALTERNATING GROUP, BURNSIDE'S CONJECTURE, CHEVALLEY GROUPS, CLASSIFICATION THEOREM, CYCLIC GROUP, FEIT-THOMPSON THEOREM, FINITE GROUP, GROUP, INVARIANT SUBGROUP, LIE-TYPE GROUP, MONSTER GROUP, SCHUR MULTIPLIER, SPORADIC GROUP, TITS GROUP, TWISTED CHEVALLEY GROUPS

Simple Harmonic Motion

Simple harmonic motion refers to the periodic sinusoidal oscillation of an object or quantity. Simple harmonic motion is executed by any quantity obeying the DIFFERENTIAL EQUATION

$$\ddot{x} + \omega_0^2 x = 0. \qquad (1)$$

where $\ddot{x}$ denotes the second DERIVATIVE of x with respect to t, and ω_0 is the angular frequency of oscillation. This ORDINARY DIFFERENTIAL EQUATION has an irregular SINGULARITY at ∞. The general solution is

$$x = A\sin(\omega_0 t) + B\cos(\omega_0 t) \qquad (2)$$

$$= C\cos(\omega_0 t + \phi), \qquad (3)$$

where the two constants A and B (or C and ϕ) are determined from the initial conditions.

Many physical systems undergoing small displacements, including any objects obeying Hooke's law, exhibit simple harmonic motion. This equation arises, for example, in the analysis of the flow of current in an electronic CL circuit (which contains a capacitor and an inductor). If a damping force such as Friction is present, an additional term $\beta\dot{x}$ must be added to the DIFFERENTIAL EQUATION and motion dies out over time.

See also DAMPED SIMPLE HARMONIC MOTION, SIMPLE HARMONIC–MOTION QUADRATIC PERTURBATION

Simple Harmonic Motion—Quadratic Perturbation

Given a simple harmonic oscillator with a quadratic perturbation ϵx^2,

$$\ddot{x} + \omega_0^2 x - \alpha\epsilon x^2 = 0. \qquad (1)$$

find the first-order solution using a perturbation method. Write

$$x \equiv x_0 + \epsilon x_1 + \ldots. \qquad (2)$$

so

$$\ddot{x} = \dot{x}_0 + \epsilon\dot{x}_1 + \ldots. \qquad (3)$$

Plugging (2) and (3) back into (1) gives

$$(\dot{x}_0 + \epsilon\dot{x}_1) + (\omega_0^2 x_0 + \omega_0^2 \epsilon x_1) - \alpha\epsilon(x_0 + 2x_0x_1\epsilon + \ldots) = 0. \qquad (4)$$

Keeping only terms of order ϵ and lower and grouping, we obtain

$$(\dot{x} + \omega_0^2 x_0) + (\dot{x}_1 + \omega_0^2 x_1 - \alpha x_0^2)\epsilon = 0. \qquad (5)$$

Since this equation must hold for all POWERS of ϵ, we can separate it into the two differential equations

$$\dot{x}_0 + \omega_0^2 x_0 = 0 \qquad (6)$$

$$\dot{x}_1 + \omega_0^2 x_1 = \alpha x_0^2. \qquad (7)$$

The solution to (6) is just

$$x_0 = A\cos(\omega_0 t + \phi). \qquad (8)$$

Setting our clock so that $\phi = 0$ gives

$$x_0 = A\cos(\omega_0 t). \qquad (9)$$

Plugging this into (7) then gives

$$\dot{x}_1 + \omega_0^2 x_1 = \alpha A^2\cos^2(\omega_0 t) \qquad (10)$$

The two homogeneous solutions to (10) are

$$x_1 = \cos(\omega_0 t) \qquad (11)$$

$$x_2 = \sin(\omega_0 t). \qquad (12)$$

The particular solution to (10) is therefore given by

$$x_p(t) = -x_1(t)\int \frac{x_2(t)g(t)}{W(t)}\,dt + x_2(t)\int \frac{x_1(t)g(t)}{W(t)}\,dt. \qquad (13)$$

where

$$g(t) = \alpha A^2\cos^2(\omega_0 t). \qquad (14)$$

and the WRONSKIAN is

$$W \equiv x_1\dot{x}_2 - \dot{x}_1 x_2 = \omega_0. \qquad (15)$$

Plugging everything into (13),

$$x_p = \alpha A^2 \left[-\cos(\omega_0 t) \int \frac{\sin(\omega_0 t)\cos^2(\omega_0 t)}{\omega_0}\, dt + \sin(\omega_0 t) \int \frac{\cos^3(\omega_0 t)}{\omega_0}\, dt \right]$$

$$= \frac{\alpha A^2}{\omega_0} \left\{ \sin(\omega_0 t) \int [1 - \sin^2(\omega_0 t)] \cos(\omega_0 t)\, dt - \cos(\omega_0 t) \int \sin(\omega_0 t) \cos^2(\omega_0 t)\, dt \right\}. \quad (16)$$

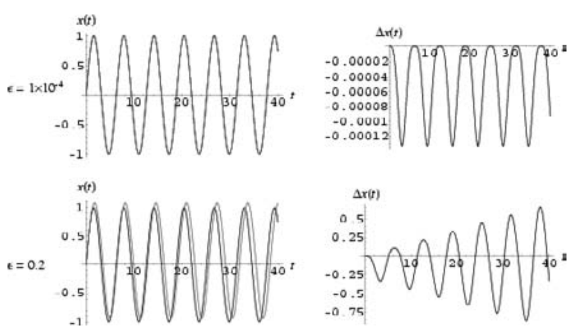
Now let

$$u \equiv \sin(\omega_0 t) \quad (17)$$

$$du = \omega_0 \cos(\omega_0 t)\, dt \quad (18)$$

$$v \equiv \cos(\omega_0 t) \quad (19)$$

$$dv = -\omega_0 \sin(\omega_0 t)\, dt. \quad (20)$$



Then

$$x_p = \frac{\alpha A^2}{\omega_0^2} \left[\sin(\omega_0 t) \int (1 - u^2)\, du + \cos(\omega_0 t) \int v^2\, dv \right]$$

$$= \frac{\alpha A^2}{\omega_0^2} \left[\sin(\omega_0 t) \left(1 - \tfrac{1}{3} u^3 \right) + \cos(\omega_0 t) \tfrac{1}{3} v^3 \right]$$

$$= \frac{\alpha A^2}{\omega_0^2} \left\{ \sin(\omega_0 t) \left[1 - \tfrac{1}{3} \sin^3(\omega_0 t) \right] + \tfrac{1}{3} \cos(\omega_0 t) \cos^3(\omega_0 t) \right\}$$

$$= \frac{\alpha A^2}{6\omega_0^2} [3 - \cos(2\omega_0 t)]. \quad (21)$$

Plugging $x_0(t)$ and (21) into (2), we obtain the solution

$$x(t) = A \cos(\omega_0 t) - \frac{\alpha A^2}{6\omega_0^2} \epsilon [\cos(2\omega_0 t) - 3]. \quad (22)$$

As can be seen in the top figure above, this solution approximates $x(t)$ only for $\epsilon \ll 1$. As the lower figure shows, the differences from the unperturbed oscillator grow stronger over time for even relatively small values of ϵ.

Simple Harmonic Oscillator

SIMPLE HARMONIC MOTION

Simple Interest

INTEREST which is paid only on the PRINCIPAL and not on the additional amount generated by previous INTEREST payments. A formula for computing simple interest is

$$a(t) = a(0)(1 + rt).$$

where $a(t)$ is the sum of PRINCIPAL and INTEREST at time t for a constant interest rate r.

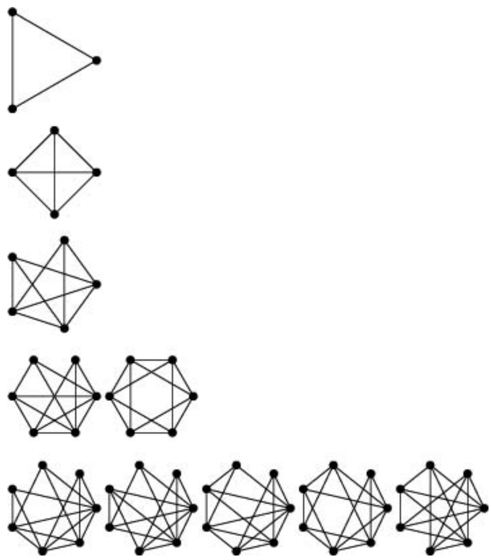
Simple Pole

A simple pole of a ANALYTIC FUNCTION f is a POLE of order one. That is, $(z - z_0)f(z)$ is an ANALYTIC FUNCTION at the pole $z = z_0$. Alternatively, its PRINCIPAL PART is $c/(z - z_0)$ for some $c \neq 0$. It is called simple because a function with a pole of order n at a can be written as the product of n functions with simple poles at z_0.

See also DIVISOR (CURVE), ESSENTIAL SINGULARITY, POLE

Simple Polygon



A POLYGON P is said to be simple (or JORDAN) if the only points of the plane belonging to two EDGES of P are the VERTICES of P. Such a polygon has a WELL DEFINED interior and exterior. Simple polygons are topologically equivalent to a DISK.

References

Toussaint, G. "Anthropomorphic Polygons." *Amer. Math. Monthly* **122**, 31–35, 1991.

Simple Polyhedron

A POLYHEDRON that is topologically equivalent to a sphere (i.e., if it were inflated, it would produce a sphere) and whose faces are SIMPLE POLYGONS. The simple polyhedra on n nodes correspond to the simple PLANAR GRAPHS with $3n-6$ edges, and are also called "simplicial polyhedra." The number of simple polyhedra on $n=1, 2, ...$ nodes are 0, 0, 1, 1, 1, 2, 5, 15, 50, 233, 1249, ... (Sloane's A000109).

Simple Random Walk

See also RANDOM WALK

Simple Ring

A NONZERO RING S whose only (two-sided) IDEALS are S itself and zero. Every commutative simple ring is a FIELD. Every simple ring is a PRIME RING.

See also FIELD, IDEAL, PRIME RING, RING

Simple Root

A ROOT having MULTIPLICITY $n=1$ is called a simple root. For example, $f(z)=(z-1)(z-2)$ has a simple root at $z_0=1$, but $g=(z-1)^2$ has a root of MULTIPLICITY 2 at $z_0=1$, which is therefore not a simple root.

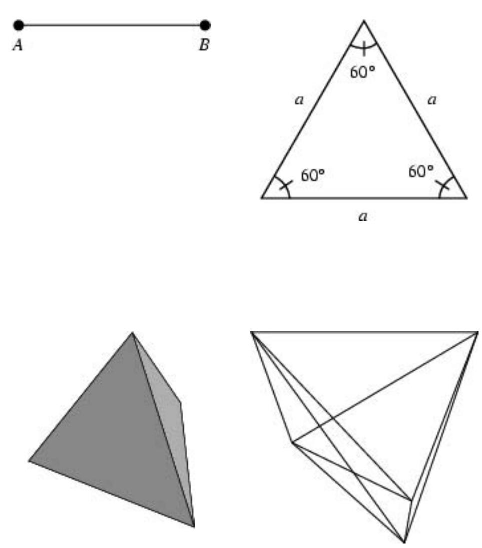
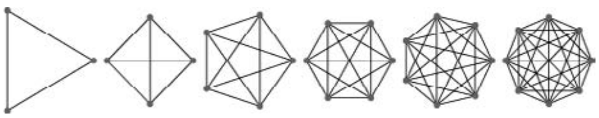
Simple Zero

SIMPLE ROOT



Simplex

The generalization of a tetrahedral region of space to n-D. The boundary of a k-simplex has $k+1$ 0-faces (VERTICES), $k(k+1)/2$ 1-faces (EDGES), and $\binom{k+1}{i+1}$ i-faces, where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. An n-D simplex can be denoted using the SCHLÄFLI SYMBOL



$$\{\underbrace{3, \ldots, 3}_{n-1}\}.$$

The simplex named because it represents the simplest possible polytope in any given space.

The CONTENT (i.e., hypervolume) of a simplex can be computed using the CAYLEY-MENGER DETERMINANT.

In 1-D, the simplex is the LINE SEGMENT $[-1, 1]$. In 2-D, the simplex $\{3\}$ is the CONVEX HULL of the EQUILATERAL TRIANGLE. In 3-D, the simplex $\{3, 3\}$ is the CONVEX HULL of the TETRAHEDRON. The simplex in 4-D (the PENTATOPE) is a regular TETRAHEDRON $ABCD$ in which a point E along the fourth dimension through the center of $ABCD$ is chosen so that $EA = EB = EC = ED = AB$. The regular simplex in n-D with $n \geq 5$ is denoted α_n.

The above figures show the graphs for the n-simplexes with $n = 2$ to 7.

Simplex Method

A method for solving problems in LINEAR PROGRAMMING. This method, invented by G. B. Dantzig in 1947, runs along EDGES of the visualization SOLID to find the best answer. In 1970, Klee and Minty constructed examples in which the simplex method required an exponential number of steps, but such cases seem never to be encountered in practical applications.

A much more efficient (POLYNOMIAL-time) ALGORITHM was found in 1984 by N. Karmarkar. This method goes through the middle of the SOLID and then transforms and warps. It offers many advantages over the simplex method (Nemirovsky and Yudin 1994).

Simplex Point Picking

Given a SIMPLEX of unit CONTENT in Euclidean d-space, pick $d+1$ points uniformly and independently at random, and denote the expected CONTENT of their CONVEX HULL by $V(d, n)$. The special values

$$V(1, n) = 1 - \frac{2}{n+1} = \frac{n-1}{n+1} \tag{1}$$

and

$$V(2, n) = 1 - \frac{2}{n+1} \sum_{k=1}^{n} \frac{1}{k} = 1 - \frac{2H_n}{n+1}, \tag{2}$$

where H_n is a HARMONIC NUMBER, are known (Buchta 1984, 1986). Not much is known about $V(3, n)$, although

$$V(3, 5) = \tfrac{5}{2} V(3, 4) \tag{3}$$

(Buchta 1983, 1986) and

$$1 - V(3, n) \sim \frac{3}{4} \frac{(\ln n)^2}{n} \tag{4}$$

(Buchta 1986).

Simplicial Complex

simplicial complexes *not a simplicial complex*

A simplicial complex is a SPACE with a TRIANGULATION. Formally, a simplicial complex K in $\mathbb{R}^n$ is a collection of SIMPLICES in $\mathbb{R}^n$ such that

1. Every face of a simplex of K is in K, and
2. The intersection of any two simplices of K is a face of each of them

(Munkres 1993, p. 7).

Objects in the space made up of only the simplices in the triangulation of the space are called SIMPLICIAL

SUBCOMPLEXES. When only simplicial complexes and SIMPLICIAL SUBCOMPLEXES are considered, defining HOMOLOGY is particularly easy (and, in fact, combinatorial because of its finite/counting nature). This kind of homology is called SIMPLICIAL HOMOLOGY.

Simplicial Homology

The type of HOMOLOGY which results when the spaces being studied are restricted to SIMPLICIAL COMPLEXES and subcomplexes.

See also SIMPLICIAL COMPLEX

Simplicial Homomorphism

Let $f : K^{(0)} \to L^{(0)}$ be a bijective correspondence such that the vertices v_0, ..., v_n of K span a SIMPLEX of K IFF $f(v_0)$, ..., $f(v_n)$ span a SIMPLEX of L. Then the induced SIMPLICIAL MAP $g : |K| \to |L|$ is a HOMEOMORPHISM, and the map g is called a simplicial homeomorphism (Munkres 1993, p. 13).

References

Munkres, J. R. *Elements of Algebraic Topology.* Perseus Press, 1993.

Simplicial Map

Let K and L be SIMPLICIAL COMPLEXES, and let $f : K^{(0)} \to L^{(0)}$ be a map. Suppose that whenever the vertices v_0, ..., v_n of K span a SIMPLEX of K, the points $f(v_0)$, ..., $f(v_n)$ are vertices of a SIMPLEX of L. Then f can be extended to a continuous map $g : |K| \to |L|$ such that

$$x = \sum_{i=0}^{n} t_i v_i$$

implies

$$g(x) = \sum_{i=0}^{n} t_i f(v_i).$$

The map g is then called the linear simplicial map induced by the vertex map f (Munkres 1993, p. 12).

Munkres, J. R. *Elements of Algebraic Topology.* Perseus Press, 1993.

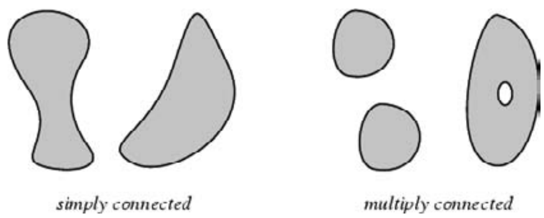
Simplicity



The number of operations needed to effect a GEOMETRIC CONSTRUCTION as determined in GEOMETROGRAPHY. If the number of operations of the five GEOMETROGRAPHIC types are denoted m_1, m_2, n_1, n_2, and n_3, respectively, then the simplicity is $m_1 + m_2 + n_1 + n_2 + n_3$ and the symbol $m_1 S_1 + m_2 S_2 + n_1 C_1 + n_2 C_2 + n_3 C_3$. It is apparently an unsolved problem to determine if a given GEOMETRIC CONSTRUCTION is of smallest possible simplicity.

Simply Connected

A CONNECTED DOMAIN is said to be simply connected (also called 1-connected) if any simple closed curve can be shrunk to a point continuously in the set. If the domain is CONNECTED but not simply, it is said to be MULTIPLY CONNECTED. In particular, a SUBSET E of $\mathbb{R}^2$ is said to be simply connected if both E and $\mathbb{R}^2 \backslash E$, where $F \backslash E$ denotes a SET DIFFERENCE, are CONNECTED.

A SPACE S is simply connected if it is 0-connected and if every MAP from the 1-SPHERE to S extends continuously to a MAP from the 2-DISK. In other words, every loop in the SPACE is contractible.

Simpson's 3/8 Rule

Let the values of a function $f(x)$ be tabulated at points x_i equally spaced by $h = x_{i+1} - x_i$, so $f_1 = f(x_1)$, $f_2 = f(x_2)$, ..., $f_4 = f(x_4)$. Then Simpson's 3/8 rule approximating the integral of $f(x)$ is given by the NEWTON-COTES-like formula

$$\int_{x_1}^{x_4} f(x)\,dx = \tfrac{3}{8}\,h(f_1 + 3f_2 + 3f_3 + f_4) - \tfrac{3}{80}\,h^5\,f^{(4)}(\xi).$$

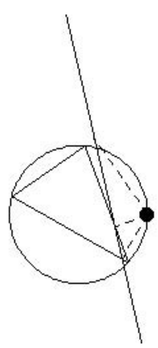
Simson Line



The Simson line is the LINE containing the feet P_1, P_2, and P_3 of the perpendiculars from an arbitrary point P on the CIRCUMCIRCLE of a TRIANGLE to the sides or their extensions of the TRIANGLE. This line was attributed to Simson by Poncelet , but is now frequently known as the Wallace-Simson line since it does not actually appear in any work of Simson (Johnson 1929, p. 137; Coxeter and Greitzer 1967, p. 41; de Guzmán 1999). The inverse statement to that given above, namely that the locus of all points P in the plane of a TRIANGLE ΔABC such that the feet of perpendiculars from the three sides of the triangle is

collinear is given by the CIRCUMCIRCLE of ΔABC, is sometimes called the Wallace-Simson theorem (Guzmán 1999).

The Simson line bisects the line HP, where H is the ORTHOCENTER (Honsberger 1995, p. 46). Moreover, the MIDPOINT of HP lies on the NINE-POINT CIRCLE (Honsberger 1995, pp. 46–47). The Simson lines of two opposite point on the CIRCUMCENTER of a triangle are PERPENDICULAR and meet on the NINE-POINT CIRCLE.

The ANGLE between the Simson lines of two points P and P' is half the ANGLE of the arc PP'. The Simson line of any VERTEX is the ALTITUDE through that VERTEX. The Simson line of a point opposite a VERTEX is the corresponding side. If $T_1T_2T_3$ is the Simson line of a point T of the CIRCUMCIRCLE, then the triangles TT_1T_2 and TA_2A_1 are directly similar.

The ENVELOPE of the Simson lines of a triangle is a DELTOID (Butchart 1939; Wells 1991, pp. 155 and 230). The area of the deltoid is half the area of the circumcircle (Wells 1991, p. 230), and MORLEY'S TRIANGLE of the starting triangle has the same orientation as the DELTOID. Each side of the triangle is tangent to the DELTOID at a point whose distance from the MIDPOINT of the side equals the chord of the NINE-POINT CIRCLE cut off by that side (Wells 1991, p. 231). If a line L is the Simson line of a point P on the CIRCUMCIRCLE of a TRIANGLE, then P is called the POLE of L (Honsberger 1995, p. 128).

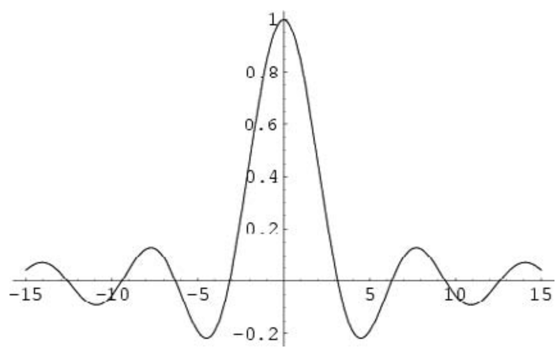
Simson's Formula

CASSINI'S IDENTITY



Sin

SINE

Sinc

SINC FUNCTION

Sinc Function

A function also called the "sampling function" that arises frequently in signal processing. There are two definitions in common use. The one adopted in this work defines

$$\operatorname{sinc}(x) \equiv \begin{cases} 1 & \text{for } x = 0 \\ \dfrac{\sin x}{x} & \text{otherwise,} \end{cases} \tag{1}$$

where $\sin x$ is the SINE function, while Woodward (1953) and Bracewell (1999, p. 62) adopt the alternative definition

$$\operatorname{sinc}_\pi(x) \equiv \begin{cases} 1 & \text{for } x = 0 \\ \dfrac{\sin(\pi x)}{(\pi x)} & \text{otherwise.} \end{cases} \tag{2}$$

The latter definition is sometimes more convenient as a result of its simple normalization,

$$\int_{-\infty}^{\infty} \operatorname{sinc}_\pi(x)\, dx = 1. \tag{3}$$

Let $\Pi(x)$ be the RECTANGLE FUNCTION, then the FOURIER TRANSFORM of $\Pi(x)$ is the sinc function

$$\mathcal{F}[\Pi(x)] = \operatorname{sinc}(\pi k). \tag{4}$$

The sinc function therefore frequently arises in physical applications such as Fourier transform spectroscopy as the so-called INSTRUMENT FUNCTION, which gives the instrumental response to a DELTA FUNCTION input. Removing the instrument functions from the final spectrum requires use of some sort of DECONVOLUTION algorithm.
The sinc function can be written as a complex INTEGRAL by noting that, for $x \neq 0$,

$$\operatorname{sinc}(nx) \equiv \frac{\sin(nx)}{nx} = \frac{1}{nx}\,\frac{e^{inx} - e^{-inx}}{2i}$$

$$= \frac{1}{2inx}\left[e^{itx}\right]_{-n}^{n} = \frac{1n}{2n}\int_{-n}^{n} e^{ixt}\, dt. \tag{5}$$

and that $\operatorname{sinc}(nx)$ and the integral both equal 1 for $x = 0$. The sinc function can also be written as the INFINITE PRODUCT

$$\operatorname{sinc} x = \prod_{k=1}^{\infty} \cos\left(\frac{x}{2^k}\right). \tag{6}$$

Definite integrals involving the sinc function include

$$\int_0^\infty \operatorname{sinc}(x)\, dx = \tfrac{1}{2}\pi \tag{7}$$

$$\int_0^\infty \operatorname{sinc}^2(x)\, dx = \tfrac{1}{2}\pi \tag{8}$$

$$\int_0^\infty \operatorname{sinc}^3(x)\, dx = \tfrac{3}{8}\pi \tag{9}$$

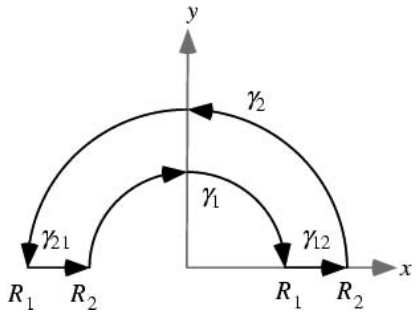
$$\int_0^\infty \operatorname{sinc}^4(x)\, dx = \tfrac{1}{3}\pi \tag{10}$$

$$\int_0^\infty \operatorname{sinc}^5(x)\, dx = \tfrac{115}{384}\pi. \tag{11}$$

These are all special cases of the amazing general result

$$\int_0^\infty \frac{\sin^a x}{x^b}\, dx = \frac{\pi^{1-c}(-1)^{\lfloor (a-b)/2 \rfloor}}{2^{a-c}(b-1)!}$$

$$\times \sum_{k=0}^{\lfloor a/2 \rfloor - c} (-1)^k \binom{a}{k} (a-2k)^{b-1} [\ln(a-2k)]^c. \tag{12}$$



where a and b are POSITIVE INTEGERS such that $a \geq b > c$, $c \equiv a - b \pmod 2$, $\lfloor x \rfloor$ is the FLOOR FUNCTION, and 0^0 is taken to be equal to 1 (Kogan). This spectacular formula simplifies in the special case when n is a POSITIVE EVEN integer to

$$\int_0^\infty \frac{\sin^{2n} x}{x^{2n}}\, dx = \frac{\pi}{2(2n-1)!}\left\langle {2n-1 \atop n-1} \right\rangle. \tag{13}$$

where $\left\langle {n \atop k} \right\rangle$ is an EULERIAN NUMBER (Kogan). The solution of the integral can also be written in terms of the RECURRENCE RELATION for the coefficients

$$c(a,\ b) = \begin{cases} \dfrac{\pi}{2^{a+1-b}} \begin{pmatrix} a-1 \\ \frac{1}{2}(a-1) \end{pmatrix} \\ \quad \text{for } b = 1 \text{ or } b = 2 \\ \dfrac{a}{(b-1)(b-2)}[(a-1)c(a-2,\ b-2) \\ \quad -a \cdot c(a,\ b-2)] \\ \quad \text{otherwise} \end{cases} \tag{14}$$

(Zimmerman).

The half-infinite integral of sinc(x) can be derived using CONTOUR INTEGRATION. In the above figure, consider the path $\gamma \equiv \gamma_1 + \gamma_{12} + \gamma_2 + \gamma_{21}$. Now write $z = Re^{i\theta}$. On an arc, $dz = iRe^{i\theta}\, d\theta$ and on the X-AXIS, $dz = e^{i\theta}\, dR$. Write

$$\int_{-\infty}^{\infty} \operatorname{sinc} x \, dx = \Im \int_{\gamma} \frac{e^{iz}}{z} \, dx. \tag{15}$$

where $\Im$ denotes the IMAGINARY POINT. Now define

$$I \equiv \int_{\gamma} \frac{e^{iz}}{z} \, dz$$

$$= \lim_{R_1 \to 0} \int_{\pi}^{0} \frac{\exp(iR_1 e^{i\theta})}{R_1 e^{i\theta}} \, i\theta R_1 e^{i\theta} \, d\theta$$

$$+ \lim_{R_1 \to 0} \lim_{R_2 \to \infty} \int_{R_1}^{R_2} \frac{e^{iR}}{R} \, dR$$

$$+ \lim_{R_2 \to \infty} \int_{0}^{\pi} \frac{\exp(iz)}{z} \, dx + \lim_{R_1 \to 0} \int_{R_2}^{R_1} \frac{e^{-iR}}{-R} (-dR). \tag{16}$$

where the second and fourth terms use the identities $e^{i0} = 1$ and $e^{i\pi} = -1$. Simplifying,

$$I = \lim_{R_1 \to 0} \int_{\pi}^{0} \exp\left(iR_1 e^{i\theta}\right) i\theta \, d\theta + \int_{0^+}^{\infty} \frac{e^{iR}}{R} \, dR$$

$$+ \lim_{R_2 \to \infty} \int_{0}^{\pi} \frac{\exp(iz)}{z} \, dz + \int_{\infty}^{0^+} \frac{e^{-iR}}{-R} (-dR)$$

$$= -\int_{0}^{\pi} i\theta \, d\theta + \int_{0^+}^{\infty} \frac{e^{iR}}{R} \, dR + 0 + \int_{-\infty}^{0-} \frac{e^{iR}}{R} \, dR. \tag{17}$$

where the third term vanishes by JORDAN'S LEMMA. Performing the integration of the first term and combining the others yield

$$I = -i\pi + \int_{-\infty}^{\infty} \frac{e^{iz}}{z} \, dz = 0. \tag{18}$$

Rearranging gives

$$\int_{-\infty}^{\infty} \frac{e^{iz}}{z} \, dz = i\pi. \tag{19}$$

so

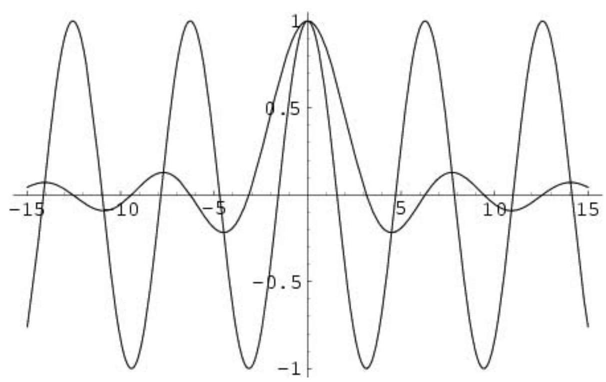
$$\int_{-\infty}^{\infty} \frac{\sin z}{z} \, dz = \pi. \tag{20}$$

The same result is arrived at using the method of RESIDUES by noting

$$I = 0 + \tfrac{1}{2} 2\pi i \operatorname*{Res}_{z=0} f(z)$$

$$= i\pi (z - 0) \frac{e^{iz}}{z} \Bigg|_{z=0} = i\pi \left[e^{iz} \right]_{z=0} = i\pi, \tag{21}$$

so



$$\Im(I) = \pi. \tag{22}$$

Since the integrand is symmetric, we therefore have

$$\int_{0}^{\infty} \frac{\sin x}{x} \, dx = \tfrac{1}{2} \pi, \tag{23}$$

giving the SINE INTEGRAL evaluated at 0 as

$$\operatorname{si}(0) = -\int_{0}^{\infty} \frac{\sin x}{x} \, dx = -\tfrac{1}{2} \pi. \tag{24}$$

An interesting property of sinc(x) is that the set of LOCAL EXTREMA of sinc(x) corresponds to its intersections with the COSINE function cos(x), as illustrated above.

Sinclair's Soap Film Problem

Find the shape of a soap film (i.e., MINIMAL SURFACE) which will fill two inverted conical FUNNELS facing each other is known as Sinclair's soap film problem (Bliss 1925, p. 121). The soap film will assume the shape of a CATENOID.

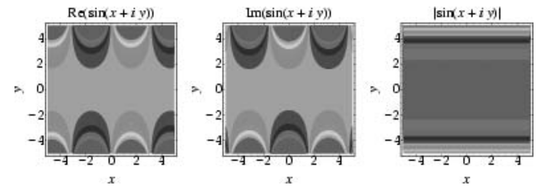
Sine



One of the basic TRIGONOMETRIC FUNCTIONS encountered in TRIGONOMETRY. Let θ be an ANGLE measured counterclockwise from the X-AXIS along the arc of the UNIT CIRCLE. Then $\sin\theta$ is the vertical coordinate of the arc endpoint. As a result of this definition, the sine function is periodic with period 2π. By the PYTHAGOREAN THEOREM, $\sin\theta$ also obeys the identity

$$\sin^2\theta+\cos^2\theta=1. \quad (1)$$

The definition of the sine function can be extended to complex arguments z using the definition

$$\sin z=\frac{e^{iz}-e^{-iz}}{2i}, \quad (2)$$

where E is the base of the NATURAL LOGARITHM and I is the IMAGINARY NUMBER. A related function known as the HYPERBOLIC SINE is similarly defined,

$$\sinh z=\tfrac{1}{2}(e^z-e^{-z}), \quad (3)$$

The sine function can be defined algebraically by the infinite sum

$$\sin x=\sum_{n=1}^{\infty}\frac{(-1)^{n-1}}{(2n-1)!}x^{2n-1} \quad (4)$$

and INFINITE PRODUCT

$$\sin x=x\prod_{n=1}^{x}\left(1-\frac{x^2}{n^2\pi^2}\right). \quad (5)$$

It is also given by the IMAGINARY PART of the complex exponential

$$\sin x=\Im\left[e^{ix}\right] \quad (6)$$

The multiplicative inverse of the sine function is the COSECANT, defined as

$$\csc x\equiv\frac{1}{\sin x}. \quad (7)$$

The sine function is also given by the slowly convergent INFINITE SERIES

$$\sin(z)=-\pi\sum_{k=1}^{\infty}\frac{\mu(k)\ln\left(\frac{n}{k}\right)\operatorname{frac}\left(\frac{kz}{2\pi}\right)}{k\ln n} \quad (8)$$

where $\mu(k)$ is the MÖBIUS FUNCTION and frac x is the FRACTIONAL PART (M. Trott).

Using the results from the EXPONENTIAL SUM FORMULAS

$$\sum_{n=0}^{N}\sin(nx)=\Im\left[\sum_{n=0}^{N}e^{inx}\right]$$

$$=\Im\left[\frac{\sin\left(\frac{1}{2}Nx\right)}{\sin\left(\frac{1}{2}x\right)}e^{i(N+1)x/2}\right]$$

$$= \frac{\sin\left(\frac{1}{2}Nx\right)}{\sin\left(\frac{1}{2}x\right)} \sin\left[\frac{1}{2}x(N+1)\right]. \qquad (9)$$

Similarly,

$$\sum_{n=0}^{\infty} p^n \sin(nx) = \Im\left[\sum_{n=0}^{\infty} p^n e^{inx}\right]$$

$$= \Im\left[\frac{1-pe^{-iz}}{1-2p\cos x+p^2}\right] = \frac{p\sin x}{1-2p\cos x+p^2}. \qquad (10)$$

The sum of $\sin^2(kx)$ can also be done in closed form,

$$\sum_{k=0}^{N} \sin^2(kx) = \tfrac{1}{4}\{1+2N-\csc x \sin[x(1+2N)\}. \qquad (11)$$

The sine function obeys the identity

$$\sin(n\theta) = 2\cos\theta\sin[(n-1)\theta] - \sin[(n-2)\theta] \qquad (12)$$

and the MULTIPLE-ANGLE FORMULA

$$\sin(nx) = \sum_{k=0}^{n} \binom{n}{k} \cos^k x \sin^{n-k} x \sin\left[\tfrac{1}{2}(n-k)\pi\right]. \qquad (13)$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT.

Cvijovic and Klinowski (1995) show that the sum

$$S_\nu(\alpha) = \sum_{k=0}^{\infty} \frac{\sin(2k+1)\alpha}{(2k+1)^\nu} \qquad (14)$$

has closed form for $\nu = 2n+1$,

$$S_{2n+1}(\alpha) = \frac{(-1)}{4(2n)!}\pi^{2n+1}E_{2n}\left(\frac{\alpha}{\pi}\right), \qquad (15)$$

where $E_n(x)$ is an EULER POLYNOMIAL.

A CONTINUED FRACTION representation of $\sin x$ is

$$\sin x = \cfrac{x}{1+\cfrac{x^2}{(2\cdot 3-x^2)\cfrac{2\cdot 3x^2}{(4\cdot 5-x^2)+\cfrac{4\cdot 5x^2}{(6\cdot 7-x^2)+\ldots}}}} \qquad (16)$$

The value of $\sin(2\pi/n)$ is IRRATIONAL for all n except 4 and 12, for which $\sin(\pi/2) = 1$ and $\sin(\pi/6) = 1/2$.

The FOURIER TRANSFORM of $\sin(2\pi k_0 x)$ is given by

$$\mathcal{F}[\sin(2\pi k_0 x)] = \int_{-\infty}^{\infty} e^{-2\pi ikx}\sin(2\pi k_0 x)\,dx$$

$$= \tfrac{1}{2}i[\delta(k+k_0) - \delta(k-k_0)]. \qquad (17)$$

Definite integrals involving $\sin x$ include

$$\int_0^\infty \sin(x^2)\,dx = \tfrac{1}{4}\sqrt{2\pi} \qquad (18)$$

$$\int_0^\infty \sin(x^3)\,dx = \tfrac{1}{6}\Gamma\left(\tfrac{1}{3}\right) \qquad (19)$$

$$\int_0^\infty \sin(x^4)\,dx = -\cos\left(\tfrac{5}{8}\pi\right)\Gamma\left(\tfrac{5}{4}\right) \qquad (20)$$

$$\int_0^\infty \sin(x^5)\,dx = \tfrac{1}{4}\left(\sqrt{5}-1\right)\Gamma\left(\tfrac{6}{5}\right), \qquad (21)$$

where $\Gamma(x)$ is the GAMMA FUNCTION.

Sine Integral

There are two types of "sine integrals" commonly defined,

$$\mathrm{Si}(x) \equiv \int_0^z \frac{\sin t}{t}\, dt \tag{1}$$

and

$$\mathrm{Si}(x) \equiv -\int_0^z \frac{\sin t}{t}\, dt \tag{2}$$

$$= \frac{1}{2i}[\mathrm{ei}(ix) - \mathrm{ei}(-ix)]$$

$$= \frac{1}{2i}[\mathrm{e}_1(ix) - \mathrm{e}_1(-ix)] \tag{3}$$

$$\mathrm{Si}(z) - \tfrac{1}{2}\pi, \tag{4}$$

where $\mathrm{ei}(x)$ is the EXPONENTIAL INTEGRAL and

$$\mathrm{e}_1(x) \equiv -\mathrm{ei}(-x). \tag{5}$$

$\mathrm{Si}(x)$ is the function returned by the *Mathematica* command `SinIntegral[x]` and displayed above. The half-infinite integral of the SINC FUNCTION is given by

$$\mathrm{si}(0) = -\int_0^\infty \frac{\sin x}{x}\, dx = -\tfrac{1}{2}\pi. \tag{6}$$

To compute the integral of a sine function times a power

$$I \equiv \int x^{2n} \sin(mx)\, dx, \tag{7}$$

use INTEGRATION BY PARTS. Let

$$u = x^{2n} \quad dv = \sin(mx)\, dx \tag{8}$$

$$du = 2nx^{2n-1}\, dx \quad v = \frac{1}{m}\cos(mx), \tag{9}$$

so

$$I = -\frac{1}{m} x^{2n}\cos(mx) + \frac{2n}{m}\int x2^{n-1}\cos(mx)\, dx. \tag{10}$$

Using INTEGRATION BY PARTS again,

$$u = x^{2n-1} \quad dv = \cos(mx)\, dx \tag{11}$$

$$du = (2n-1)x^{2n-2}\, dx \quad v\frac{1}{m}\sin(mx) \tag{12}$$

$$\int x^{2n}\sin(mx)\, dx = -\frac{1}{m}x^{2n}\cos(mx)$$

$$+\frac{2n}{m}\left[\frac{1}{m}x^{2n-1}\cos(mx) - \frac{2n-1}{m}\int x^{2n-2}\sin(mx)\, dx\right]$$

$$= -\frac{1}{m}x^{2n}\sin(mx) + \frac{2n}{m^2}x^{2n-1}\sin(mx)$$

$$-\frac{(2n)(2n-1)}{m^2}\int x^{2n-2}\sin(mx)\, dx$$

$$= -\frac{1}{m}x^{2n}\cos(mx) + \frac{2n}{m^2}x^{2n-1}\sin(mx) + \ldots$$

$$+\frac{(2n)!}{m^{2n}}\int x^0 \sin(mx)\, dx$$

$$= -\frac{1}{m}x^{2n}\cos(mx) + \frac{2n}{m^2}x^{2n-1}\sin(mx) + \ldots$$

$$-\frac{(2n)!}{m^{2n+1}}\cos(mx)$$

$$= \cos(mx)\sum_{k=0}^{n}(-1)^{k+1}\frac{(2n)!}{(2n-2k)!m^{2k+1}}x^{2n-2k}$$

$$+\sin(mx)\sum_{k=1}^{n}(-1)^{k+1}\frac{(2n)!}{(2k-2n-1)!m^{2k}}x^{2n-2k+1} \tag{13}$$

Letting $k' \equiv n - k$, so

$$\int x^{2n}\sin(mx)\, dx$$

$$= \cos(mx)\sum_{k=1}^{n}(-1)^{n-k+1}\frac{(2n)!}{(2k)!m^{2n-2k+1}}x^{2k}$$

$$+\sin(mx)\sum_{k=0}^{n-1}(-1)^{n-k+1}\frac{(2n)!}{(2k-1)!m^{2n-2k}}x^{2k+1}$$

$$= (-1)^{n+1}(2n)!\left[\cos(mx)\sum_{k=0}^{n}\frac{(-1)^k}{(2k)!m^{2n-2k+1}}x^{2k}\right.$$

$$\left.+\sin(mx)\sum_{k=1}^{n}\frac{(-1)^{k+1}}{(2k-3)!m^{2n-2k+2}}x^{2k-1}\right]. \tag{14}$$

General integrals OF THE FORM

$$I(k, l) = \int_0^\infty \frac{\sin^k x}{x^l}\, dx \tag{15}$$

are related to the SINC FUNCTION and can be computed analytically.

Sine Surface

The surface given by the PARAMETRIC EQUATIONS

$$x = a \sin u \quad (1)$$

$$y = a \sin v \quad (2)$$

$$z = a \sin(u+v). \quad (3)$$

The coefficients of the FIRST FUNDAMENTAL FORM are

$$E = a^2\left[\cos^2 u + \cos^2(u+v)\right] \quad (4)$$

$$F = a^2 \cos^2(u+v) \quad (5)$$

$$G = a^2\left[\cos^2 v + \cos^2(u+v)\right], \quad (6)$$

the SECOND FUNDAMENTAL FORM coefficients are

$$e = -\frac{a\cos v\sin v}{\sqrt{\cos^2 u\cos^2 v + (\cos^2 u + \cos^2 v)\cos^2(u+v)}} \quad (7)$$

$$f = -\frac{a\cos u\cos v\sin(u+v)}{\sqrt{\cos^2 u\cos^2 v + (\cos^2 u + \cos^2 v)\cos(u+v)}} \quad (8)$$

$$g = -\frac{a\cos u\sin u}{\sqrt{\cos^2 u\cos^2 v + (\cos^2 u + \cos^2 v)\cos^2(u+v)}} \quad (9)$$

the AREA ELEMENT is

$$dS = a^2 \times \sqrt{\cos^2 u\cos^2 v + (\cos^2 u + \cos^2 v)\cos^2(u+v)}, \quad (10)$$

the Gaussian curvature is

$$k = \frac{\cos u\cos v\left[\sin u\sin v - \cos u\cos v\sin^2(u+v)\right]}{\left[a\cos^2 u\cos^2 v + a(\cos^2 u + \cos^2 v)\cos^2(u+v)\right]^2}, \quad (11)$$

and the MEAN CURVATURE is a complicated expression.

Sine-Gordon Equation

A PARTIAL DIFFERENTIAL EQUATION which appears in differential geometry and relativistic field theory. Its name is a wordplay on its similar form to the KLEIN-GORDON EQUATION. The sine-Gordon equation is

$$v_{tt} - v_{xx} + \sin v = 0. \quad (1)$$

where v_{tt} and v_{xx} are PARTIAL DERIVATIVES. The equation can be transformed by defining

$$\xi \equiv \tfrac{1}{2}(x-t) \quad (2)$$

$$\eta \equiv \tfrac{1}{2}(x+t). \quad (3)$$

Then, by the CHAIN RULE,

$$\frac{\partial}{\partial x} = \frac{\partial\xi}{\partial x}\frac{\partial}{\partial\xi} + \frac{\partial\eta}{\partial x}\frac{\partial}{\partial\eta} \quad (4)$$

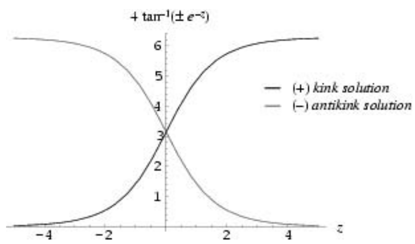
$$= \frac{1}{2}\left(\frac{\partial}{\partial\xi} + \frac{\partial}{\partial\eta}\right) \quad (5)$$

$$\frac{\partial}{\partial t} = \frac{\partial\xi}{\partial t}\frac{\partial}{\partial\xi} + \frac{\partial\eta}{\partial t}\frac{\partial}{\partial\eta} \quad (6)$$

$$= \frac{1}{2}\left(\frac{\partial}{\partial\eta} + \frac{\partial}{\partial\xi}\right) \quad (7)$$

This gives

$$\frac{\partial^2 v}{\partial x^2} = \frac{1}{4}\left(\frac{\partial}{\partial\xi} + \frac{\partial}{\partial\eta}\right)\left(\frac{\partial v}{\partial\xi} + \frac{\partial v}{\partial\eta}\right)$$



$$= \frac{1}{4}\left(\frac{\partial^2 v}{\partial\xi^2} + 2\frac{\partial^2 v}{\partial\xi\partial\eta} + \frac{\partial^2 v}{\partial\eta^2}\right) \quad (8)$$

$$\frac{\partial^2 v}{\partial t^2} = \frac{1}{4}\left(\frac{\partial}{\partial \eta} - \frac{\partial}{\partial \xi}\right)\left(\frac{\partial v}{\partial \eta} - \frac{\partial v}{\partial \xi}\right)$$

$$= \frac{1}{4}\left(\frac{\partial^2 v}{\partial \xi^2} - 2\frac{\partial^2 v}{\partial \xi \partial \eta} + \frac{\partial^2 v}{\partial \eta^2}\right) \tag{9}$$

Plugging in gives

$$v\xi_\eta = \sin v. \tag{10}$$

Traveling wave analysis by setting $v(x,\ t) = g(z)$ yields after one integration

$$z - z_0 = \sqrt{c^2 - 1}\int \frac{df}{\sqrt{2\left[d - 2\sin^2\left(\frac{1}{2}f\right)\right]}} \tag{11}$$

where d is a constant of integration (Tabor 1989, p. 306). For the particular case $d = 0$,

$$z - z_0 = \pm\sqrt{1 - c^2}\,\ln\left[\pm\tan\left(\tfrac{1}{4}f\right)\right], \tag{12}$$

so integrating gives

$$f(z) = \pm 4\tan^{-1}[e^{\pm(z - z_0)/(1 - c^2)^{1/2}}]. \tag{13}$$

The solution with the plus sign is called the "kink solution," while that with the minus sign is called the "antikink solution" (Tabor 1989, pp. 306–307).

Another solution to the sine-Gordon equation is given by making the substitution $v(\xi,\ \eta) = f(z)$, where $z = \xi\eta$, giving the ORDINARY DIFFERENTIAL EQUATION

$$zf'' + f' = \sin f. \tag{14}$$

However, this cannot be solved analytically, since letting $g \equiv e^{if}$ gives

$$g'' - \frac{g'^2}{f} + \frac{2g' - g^2 + 1}{2z} = 0. \tag{15}$$

which is the third PAINLEVÉ TRANSCENDENT (Tabor 1989, p. 309).

Now looking for a solution OF THE FORM

$$v(x,\ t) = 4\tan^{-1}\left[\frac{\phi(x)}{\psi(t)}\right] \tag{16}$$

gives

$$\frac{\psi^2}{\phi}\ \phi_{xx} + \frac{\phi^2}{\psi}\ \psi_{tt}$$
$$= (\psi^2 + 2\psi_t - \psi\psi_{tt}) + (-\phi^2 + 2\phi_x - \phi\phi_{xx}). \tag{17}$$

Further differentiation gives

$$\frac{(\phi_{xx}\phi)_x}{\phi\phi_x} = -\frac{(\psi_{tt}/\psi)_t}{\psi\psi_t} = -4k^2. \tag{18}$$

where k is a separation constant. Integrating twice then gives

$$\phi_{xx} = -k^2\phi^4 + m^2\phi^2 + n^2 \tag{19}$$

$$\psi_{tt} = k^2\psi^4 + (m^2 - 1)\psi^2 - n^2, \tag{20}$$

which can be solved in terms of ELLIPTIC FUNCTIONS (Infeld and Rowlands 2000, pp. 178–179).

A single-SOLITON solution is obtained when $k = n = 0$, $m > 1$:

$$v = 4\tan^{-1}\left[\exp\left(\frac{\pm x - \beta t}{\sqrt{1 - \beta^2}}\right)\right], \tag{21}$$

where

$$\beta \equiv \frac{\sqrt{m^2 - 1}}{m}, \tag{22}$$

with the plus and minus signs corresponding to the soliton and antisoliton solutions. A two-SOLITON solution exists with $k = 0$, $m > 1$:

$$v = 4\tan^{-1}\left[\frac{\beta\sinh(\beta m x)}{\cosh(\beta m t)}\right]. \tag{23}$$

A two-kink solution is given by

$$v = 4\tan^{-1}\left[\frac{m\sinh\left(\frac{x}{\sqrt{1 - m^2}}\right)}{\beta\cosh\left(\frac{mt}{\sqrt{1 - m^2}}\right)}\right] \tag{24}$$

(Perring and Skyrme 1962; Drazin 1988; Tabor 1989, pp. 307–308).

A "breather" solution occurs for $k \neq 0$, $n = 0$, $m^2 < 1$:

$$v = -4\tan^{-1}\left[\frac{m}{\sqrt{1 - m^2}}\ \frac{\sin\left(\sqrt{1 - m^2 t}\right)}{\cosh(mx)}\right]. \tag{25}$$

For a fixed $x,\ v$, this is a periodic function of t with frequency $2\pi/\sqrt{1 - m^2}$ (Infeld and Rowlands 2000, p. 179).

The so-called double sine-Gordon equation is given by

$$u_{xt} \pm \left[\sin u + \eta\sin\left(\tfrac{1}{2}u\right)\right] = 0 \tag{26}$$

(Calogero and Degasperis 1982, p. 135; Zwillinger 1997, p. 135).

Sines Law

LAW OF SINES

Sine-Tangent Theorem

If

$$\frac{\sin\alpha}{\sin\beta}=\frac{m}{n},$$

then

$$\frac{\tan\left[\frac{1}{2}(\alpha-\beta)\right]}{\tan\left[\frac{1}{2}(\alpha+\beta)\right]}=\frac{m-n}{m+n},$$

Single-Valued Function

A function which has the same value at every point z_0 independent of the path along which it is reached by ANALYTIC CONTINUATION (Knopp 1996, p. 93).

See also SINGLE-VALUED FUNCTION

References

Knopp, K. "Multiple-Valued Functions." Section II in *Theory of Functions Parts I and II, Two Volumes Bound as One, Part II.* New York: Dover, pp. 93–146, 1996.

Singly Even Number

An EVEN NUMBER OF THE FORM $4n+2$ (i.e., an INTEGER which is DIVISIBLE by 2 but not by 4). The first few for $n=0$, 1, 2, ... are 2, 6, 10, 14, 18, ... (Sloane's A016825)

See also DOUBLY EVEN NUMBER, EVEN NUMBER, ODD NUMBER

References

Singular Homology

The general type of HOMOLOGY which is what mathematicians generally mean when they say "homology." Singular homology is a more general version than Poincaré's original SIMPLICIAL HOMOLOGY.

See also HOMOLOGY (TOPOLOGY), SIMPLICIAL HOMOLOGY

Singular Knot

This entry contributed by SERGEI DUZHIN

A SMOOTH MAP $f:\mathbb{S}^1\to R^3$ whose IMAGE has singularities. In particular, in the theory of Vassiliev's knot invariants, singular knots with a finite number of ORDINARY DOUBLE POINTS play an important role.

See also ORDINARY DOUBLE POINT, VASSILIEV INVARIANT

Singular Matrix

A SQUARE MATRIX that not have a MATRIX INVERSE. A matrix is singular IFF its DETERMINANT is 0. For example, there are 10 singular 2×2 (0,1)-MATRICES:

$$\begin{bmatrix}0&0\\0&0\end{bmatrix},\begin{bmatrix}0&0\\0&1\end{bmatrix},\begin{bmatrix}0&0\\1&0\end{bmatrix},\begin{bmatrix}0&0\\1&1\end{bmatrix},\begin{bmatrix}0&1\\0&0\end{bmatrix}$$

$$\begin{bmatrix}0&1\\0&1\end{bmatrix},\begin{bmatrix}1&0\\0&0\end{bmatrix},\begin{bmatrix}1&0\\1&0\end{bmatrix},\begin{bmatrix}1&1\\0&0\end{bmatrix},\begin{bmatrix}1&1\\1&1\end{bmatrix}.$$

The following table gives the numbers of singular $n\times n$ matrices for certain matrix classes.

matrix type	Sloane	counts for $n=1$, 2, ...
(−1, 0, 1)-matrices	A000000	1, 33, 7875, ...
(−1, 1)-matrices	A000000	0, 8, 320, 43264, ...
(0, 1)-matrices	A046747	1, 10, 338, 42976, ...

Singular Measure

Two COMPLEX MEASURES μ and ν on a MEASURE SPACE X, are mutually singular if they are supported on different subsets. More precisely, $X = A \cup B$ where A and B are two DISJOINT SETS such that the following hold for any MEASURABLE SET E,

1. The sets $A \cap E$ and $B \cap E$ are measurable.
2. The TOTAL VARIATION MEASURE of μ is supported on A and that of ν on B, i.e.,

$$\|\mu\|(B \cap E) = 0 = \|\nu\|(A \cap E).$$

The relation of two measures being singular, written as $\mu \perp \nu$, is plainly symmetric. Nevertheless, it is sometimes said that "ν is singular with respect to μ."

A discrete singular measure (with respect to LEBESGUE MEASURE on the reals) is a MEASURE λ supported at 0, say $\lambda(E) = 1$ iff $0 \in E$. In general, a MEASURE λ is concentrated on a SUBSET A if $\lambda(E) = \lambda(E \cap A)$. For instance, the measure above is concentrated at 0.

Singular Point (Algebraic Curve)

A singular point of an ALGEBRAIC CURVE is a point where the curve has "nasty" behavior such as a CUSP or a point of self-intersection (when the underlying field K is taken as the REALS). More formally, a point (a, b) on a curve $f(x, y) = 0$ is singular if the x and y PARTIAL DERIVATIVES of f are both zero at the point (a, b). (If the field K is not the REALS or COMPLEX NUMBERS, then the PARTIAL DERIVATIVE is computed formally using the usual rules of CALCULUS.)

Consider the following two examples. For the curve

$$x^3 - y^2 = 0.$$

the CUSP at (0, 0) is a singular point. For the curve

$$x^2 + y^2 = -1.$$

$(0, i)$ is a nonsingular point and this curve is nonsingular.

See also ALGEBRAIC CURVE, CUSP

Singular Point (Differential Equation)

Consider a second-order ORDINARY DIFFERENTIAL EQUATION

$$y'' + P(x)y' + Q(x)y = 0.$$

If $P(x)$ and $Q(x)$ remain FINITE at $x = x_0$, then x_0 is called an ORDINARY POINT. If either $P(x)$ or $Q(x)$ diverges as $x \to x_0$, then x_0 is called a singular point. Singular points are further classified as follows:

1. If either $P(x)$ or $Q(x)$ diverges as $x \to x_0$ but $(x - x_0)P(x)$ and $(x - x_0)^2 Q(x)$ remain FINITE as $x \to x_0$, then $x = x_0$ is called a REGULAR SINGULAR POINT (or NONESSENTIAL SINGULARITY).
2. If $P(x)$ diverges more quickly than $1/(x - x_0)$, so $(x - x_0)P(x)$ approaches INFINITY as $x \to x_0$, or $Q(x)$ diverges more quickly than $1/(x - x_0)^2 Q$ so that $(x - x_0)^2 Q(x)$ goes to INFINITY as $x \to x_0$, then x_0 is called an IRREGULAR SINGULARITY (or ESSENTIAL SINGULARITY).

See also IRREGULAR SINGULARITY, REGULAR SINGULAR POINT, SINGULARITY

References
Arfken, G. "Singular Points." §8.4 in *Mathematical Methods for Physicists, 3rd ed.* Orlando, FL: Academic Press, pp. 451–454, 1985.

Singular Point (Function)

Singular points (also simply called "singularities") are points z_0 in the DOMAIN of a FUNCTION f where f fails to be ANALYTIC. ISOLATED SINGULARITIES may be classified as ESSENTIAL SINGULARITIES, POLES, or REMOVABLE SINGULARITIES.

ESSENTIAL SINGULARITIES are POLES of INFINITE order.

A POLE of order n is a singularity z_0 of $f(z)$ for which the function $(z - z_0)^n f(z)$ is nonsingular and for which $(z - z_0)^k f(z)$ is singular for $k = 0, 1, \ldots, n - 1$.

REMOVABLE SINGULARITIES are singularities for which it is possible to assign a COMPLEX NUMBER in such a way that $f(z)$ becomes ANALYTIC. For example,

the function $f(z) = z^2/z$ has a REMOVABLE SINGULARITY at 0, since $f(z) = z$ everywhere but 0, and $f(z)$ can be set equal to 0 at $z = 0$. REMOVABLE SINGULARITIES are not POLES.

The function $f(z) = \csc(1/z)$ has POLES at $z = 1/(2\pi n)$, and a nonisolated singularity at 0.

See also ESSENTIAL SINGULARITY, IRREGULAR SINGULARITY, ORDINARY POINT, POLE, REGULAR SINGULAR POINT, REMOVABLE SINGULARITY, SINGULAR POINT (DIFFERENTIAL EQUATION)

References

Arfken, G. "Singularities." §7.1 in *Mathematical Methods for Physicists, 3rd ed.* Orlando, FL: Academic Press, pp. 396–400, 1985.

Singular Series

$$\rho_{2s}(n) = \frac{\pi^8}{\Gamma(s)} n^{s-1} \sum_{p,\, q} \left(\frac{S_{p,\, q}}{q}\right)^{2s} e^{2np\pi i/q},$$

where $S_{p,\, q}$ is a GAUSSIAN SUM, and $\Gamma(s)$ is the GAMMA FUNCTION.

Singular System

A system is singular if its CONDITION NUMBER is INFINITE and ILL-CONDITIONED if it is too large.

See also CONDITION NUMBER, ILL-CONDITIONED MATRIX

Singular Value

There are two types of singular values, one in the context of elliptic integrals, and the other in linear algebra. For a MATRIX A, the values

$$\sqrt{\lambda_j(\mathsf{A}^*\mathsf{A})}, \tag{1}$$

where λ_j is an EIGENVALUE and A^* is the ADJOINT MATRIX, are called singular values (Marcus and Minc 1992, p. 69). Singular values can be found using the *Mathematica* command `SingularValues[m]`, which returns the so-called SINGULAR VALUE DECOMPOSITION as a list $\{u, w, v\}$, where u and v are matrices and w is the list of the singular values.

If

$$\mathsf{A} = \mathsf{U}\mathsf{H}. \tag{2}$$

where U is a UNITARY MATRIX and H is a HERMITIAN MATRIX, then the EIGENVALUES of H are the singular values of A.

For elliptic integrals, a MODULUS k_r such that

$$\frac{K'(k_r)}{K(k_r)} = \sqrt{r}, \tag{3}$$

where $K(k)$ is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND, and $K'(k_r) \equiv K\left(\sqrt{1-k_r^2}\right)$. The ELLIPTIC LAMBDA FUNCTION $\lambda^*(r)$ gives the value of k_r. Abel (quoted in Whittaker and Watson 1990, p. 525) proved that if r is an INTEGER, or more generally whenever

$$\frac{K'(k)}{K(k)} = \frac{a + b\sqrt{n}}{c + d\sqrt{n}}, \tag{4}$$

where a, b, c, d, and n are INTEGERS, then the MODULUS k is the ROOT of an algebraic equation with INTEGER COEFFICIENTS.

Singular Value Decomposition

A decomposition of a matrix A into the form

$$\mathsf{A} = \mathsf{U}^*\mathsf{D}\mathsf{V},$$

where U is a UNITARY MATRIX, U^* is its ADJOINT MATRIX, and D is a DIAGONAL MATRIX whose elements are the SINGULAR VALUES of the original matrix. If A is a COMPLEX MATRIX, then there always exists such a decomposition with positive singular values (Golub and van Loan 1996, pp. 70 and 73).

Singular value decomposition is implemented in *Mathematica* as `SingularValues[m]`, which returns a list $\{u, w, v\}$, where u and v are matrices and w is a list of the singular values.

Sinusoidal Spiral

A curve OF THE FORM

$$r^n = a^n \cos(n\theta)$$

with n RATIONAL, which is not a true SPIRAL. Sinusoidal spirals were first studied by Maclaurin. Special cases are given in the following table.

n	Curve
-2	HYPERBOLA
-1	LINE
$-\frac{1}{2}$	PARABOLA
$-\frac{1}{3}$	TSCHIRNHAUSEN CUBIC
$\frac{1}{3}$	CAYLEY'S SEXTIC
$\frac{1}{2}$	CARDIOID
1	CIRCLE
2	LEMNISCATE

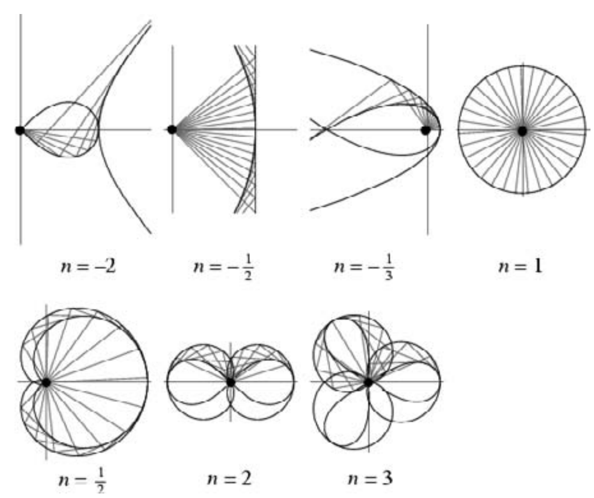
Sinusoidal Spiral Inverse Curve



The INVERSE CURVE of a SINUSOIDAL SPIRAL

$$r = a^{(1/n)}[\cos(nt)]^{1/n}$$

with INVERSION CENTER at the origin and inversion radius k is another SINUSOIDAL SPIRAL

$$r = ka^{(1/n)}[\cos(nt)]^{1/n},$$

Sinusoidal Spiral Pedal Curve

The PEDAL CURVE of a SINUSOIDAL SPIRAL

$$r = a^{(1/n)}[\cos(nt)]^{1/n}$$

with PEDAL POINT at the center is another SINUSOIDAL SPIRAL

$$x = \cos^{1+1/n}(nt)\cos[(n+1)t]$$

$$y = \cos^{1+1/n}(nt)\sin[(n+1)t].$$

See also PEDAL CURVE, SINUSOIDAL SPIRAL

Sister Celine's Method

A method for finding RECURRENCE RELATIONS for hypergeometric polynomials directly from the series expansions of the polynomials. The method is effective and easily implemented, but usually slower than ZEILBERGER'S ALGORITHM. Given a sum $f(n) = \Sigma_k F(n, k)$, the method operates by finding a recur-

rence of the form

$$\sum_{i=0}^{I}\sum_{j=0}^{J} a_{ij}(n)F(n-j,\ k-i)=0$$

by proceeding as follows (Petkovsek *et al.* 1996, p. 59):

1. Fix trial values of I and J.
2. Assume a recurrence formula of the above form where $a_{ij}(n)$ are to be solved for.
3. Divide each term of the assumed recurrence by $F(n,\ k)$ and reduce every ratio $F(n-j,\ k-i)/F(n,\ k)$ by simplifying the ratios of its constituent factorials so that only RATIONAL FUNCTIONS in n and k remain.
4. Put the resulting expression over a common DENOMINATOR, then collect the numerator as a POLYNOMIAL in k.
5. Solve the system of linear equations that results after setting the coefficients of each power of k in the NUMERATOR to 0 for the unknown coefficients a_{ij}.
6. If no solution results, start again with larger I or J.

Under suitable hypotheses, a "fundamental theorem" (Verbaten 1974, Wilf and Zeilberger 1992, Petkovsek *et al.* 1996) guarantees that this algorithm always succeeds for large enough I and J (which can be estimated in advance). The theorem also generalizes to multivariate sums and to q- and multi-q-sums (Wilf and Zeilberger 1992, Petkovsek *et al.* 1996).

Site Percolation

site percolation *bond percolation*

A PERCOLATION which considers the lattice vertices as the relevant entities (left figure).

See also BOND PERCOLATION, PERCOLATION THEORY

Siteswap

A siteswap is a sequence encountered in JUGGLING in which each term is a POSITIVE integer, encoded in BINARY. The transition rule from one term to the next consists of changing some 0 to 1, subtracting 1, and then dividing by 2, with the constraint that the DIVISION by two must be exact. Therefore, if a term is EVEN, the bit to be changed must be the units bit. In siteswaps, the number of 1-bits is a constant.

Each transition is characterized by the bit position of the toggled bit (denoted here by the numeral on top of the arrow). For example,

$$111 \xrightarrow{5} 10011 \xrightarrow{2} 1011 \xrightarrow{5} 10101 \xrightarrow{1} 1011 \xrightarrow{2} 111$$

$$\xrightarrow{6} 100011 \xrightarrow{3} 10101 \xrightarrow{3} 1110 \xrightarrow{0} 111 \xrightarrow{4} 1011 \ldots$$

The second term is given from the first as follows: 000111 with bit 5 flipped becomes 100111, or 39. Subtract 1 to obtain 38 and divide by two to obtain 19, which is 10011.

Six Exponentials Theorem

Let x_1 and x_2 be two linearly independent complex numbers, and let y_1, y_2, y_3 be three linearly independent complex numbers. Then at least one of

$$e^{x_1y_1},\ e^{x_1y_2},\ e^{x_1y_3},\ e^{x_2y_1},\ e^{x_2y_2},\ e^{x_2y_3}$$

is TRANSCENDENTAL (Waldschmidt 1979, p. 3.5). This theorem is due to Siegel, Schneider, Lang, and Ramachandra. The corresponding statement obtained by replacing y_1, y_2, y_3 with y_1, y_2 is called the FOUR EXPONENTIALS CONJECTURE and remains unproven.

WIGNER 6*J*-SYMBOL

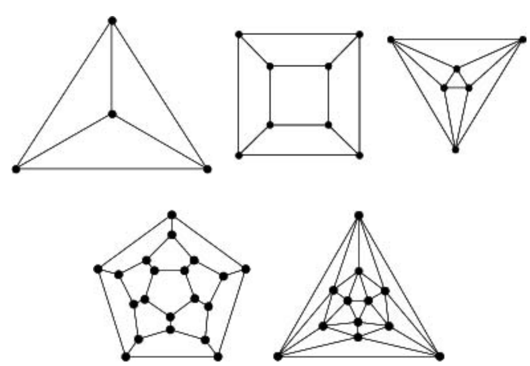
Six-Sphere Coordinates

6-SPHERE COORDINATES

Skein Relationship



A relationship between KNOT POLYNOMIALS for links in different orientations (denoted below as L_+, L_0, and L_-). J. H. Conway was the first to realize that the ALEXANDER POLYNOMIAL could be defined by a relationship of this type.

See also ALEXANDER POLYNOMIAL, HOMFLY POLYNOMIAL, SIGNATURE (KNOT)

Skeleton

In ALGEBRAIC TOPOLOGY, a p-skeleton is a SIMPLICIAL SUBCOMPLEX of K which is the collection of all SIMPLICES of K of dimension at most p, denoted $K^{(p)}$.

The GRAPH obtained by replacing the faces of a polyhedron with its edges and vertices is therefore the skeleton of the polyhedron. The polyhedral graphs corresponding to the skeletons of PLATONIC SOLIDS are illustrated above. The number of topologically distinct skeletons $N(n)$ with n VERTICES for $n = 4, 5, 6, ...$ are 1, 2, 7, 18, 52, ... (Sloane's A006869).

Skeleton Division

A LONG DIVISION in which most or all of the digits are replaced by a symbol (usually asterisks) to form a CRYPTARITHM.

See also CRYPTARITHM

Skew Conic

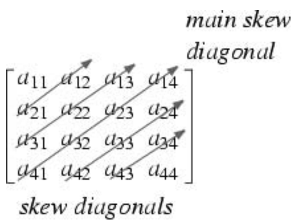
Also known as a GAUCHE CONIC, SPACE CONIC, TWISTED CONIC, or CUBICAL CONIC SECTION. A third-order SPACE CURVE having up to three points in common with a plane and having three points in common with the plane at infinity. A skew cubic is determined by six points, with no four of them COPLANAR. A line is met by up to four tangents to a skew cubic.

A line joining two points of a skew cubic (REAL or conjugate imaginary) is called a SECANT of the curve, and a line having one point in common with the curve is called a SEMISECANT or TRANSVERSAL. Depending on the nature of the roots, the skew conic is classified as follows:

1. The three ROOTS are REAL and distinct (CUBICAL HYPERBOLA).
2. One root is REAL and the other two are COMPLEX CONJUGATES (CUBICAL ELLIPSE).
3. Two of the ROOTS coincide (CUBICAL PARABOLIC HYPERBOLA).
4. All three ROOTS coincide (CUBICAL PARABOLA).

See also CONIC SECTION, CUBICAL ELLIPSE, CUBICAL HYPERBOLA, CUBICAL PARABOLA, CUBICAL PARABOLIC HYPERBOLA

Skew Coordinate System



A system of CURVILINEAR COORDINATES in which each family of surfaces intersects the others at angles other than right angles.

See also CURVILINEAR COORDINATES, ORTHOGONAL COORDINATE SYSTEM

References

Moon, P. and Spencer, D. E. *Field Theory Handbook, Including Coordinate Systems, Differential Equations, and Their Solutions, 2nd ed.* New York: Springer-Verlag, p. 1, 1988.

Skew Diagonal

A diagonal of a SQUARE MATRIX which is traversed in the "northeast" direction. "The" skew diagonal (or "secondary diagonal") of an $n \times n$ square matrix is the skew diagonal from a_{n1} to a_{1n}.

See also DIAGONAL

Skew Field

A FIELD in which the commutativity of multiplication is not required, more commonly called a DIVISION ALGEBRA.

See also DIVISION ALGEBRA, FIELD

Skew Hermitian Matrix

A SQUARE MATRIX A is skew Hermitian if is satisfies

$$\mathsf{A}^* = -\mathsf{A}, \qquad (1)$$

where A^* is the ADJOINT MATRIX. For example, the matrix

$$\begin{bmatrix} i & 1+i & 2i \\ -1+i & 5i & 3 \\ 2i & -3 & 0 \end{bmatrix} \qquad (2)$$

is a skew Hermitian matrix. A matrix m can be tested to see if it is skew Hermitian using the *Mathematica* function

```
SkewHermitianQ[m_List?MatrixQ] := (m === -Conjugate@Transpose@m)
```

The set of $n \times n$ skew Hermitian matrices is a VECTOR SPACE, and the COMMUTATOR

$$[\mathsf{A}, \mathsf{B}] = \mathsf{AB} - \mathsf{BA} \qquad (3)$$

of two skew Hermitian matrices is skew Hermitian. Hence, the skew Hermitian matrices are a LIE ALGEBRA, which is related to the LIE GROUP of UNITARY MATRICES. In particular, suppose $\mathsf{A}(t)$ is a path of unitary matrices through $\mathsf{A}(0) = \mathsf{I}$, i.e.,

$$\mathsf{A}(t) = \mathsf{A}^*(t) = \mathsf{I} \qquad (4)$$

for all t, where A^* is the ADJOINT MATRIX and I is the IDENTITY MATRIX. The DERIVATIVE at $t = 0$ of both sides must be equal so

$$\left.\frac{d\mathsf{A}}{dt}\right|_{t=0} + \left.\frac{d\mathsf{A}^*}{dt}\right|_{t=0} = 0. \qquad (5)$$

That is, the DERIVATIVE of $\mathsf{A}(t)$ at the identity must be a skew Hermitian matrix.

The EXPONENTIAL MAP of a skew Hermitian matrix is a UNITARY MATRIX.

See also ADJOINT MATRIX, HERMITIAN MATRIX, SKEW SYMMETRIC MATRIX, UNITARY MATRIX

Ayres, F. Jr. *Theory and Problems of Matrices.* New York: Schaum, pp. 13 and 118, 1962.

Skew Lines

Two or more LINES which have no intersections but are not PARALLEL, also called AGONIC LINES. Since two LINES in the PLANE must intersect or be PARALLEL, skew lines can exist only in three or more DIMENSIONS.

Three skew lines always define a one-sheeted HYPERBOLOID, except in the case where they are all parallel to a single PLANE but not to each other. In this case, they determine a HYPERBOLIC PARABOLOID (Hilbert and Cohn-Vossen 1999, p. 15).

Skew Quadrilateral

A four-sided QUADRILATERAL not contained in a plane. The lines connecting the midpoints of opposite sides of a skew quadrilateral intersect (and bisect) each other (Steinhaus 1983).

The problem of finding the minimum bounding surface of a skew quadrilateral was solved by Schwarz (Schwarz 1890, Wells 1991) in terms of ABELIAN INTEGRALS and has the shape of a SADDLE. It is given by solving

$$\left(1+f_y^2\right)f_{xy}-2f_xf_yf_{xy}+\left(1+f_x^2\right)f_{yy}=0.$$

Skew Symmetric Matrix

A SQUARE MATRIX A is skew symmetric if

$$\mathsf{A}^{\mathrm{T}}=-\mathsf{A}, \tag{1}$$

with A^{T} denoting the matrix TRANSPOSE. For example,

$$\mathsf{A}=\begin{bmatrix}0 & -1\\ 1 & 0\end{bmatrix} \tag{2}$$

is a skew symmetric matrix. The set of $n\times n$ skew symmetric matrices is denoted $o(n)$. A matrix m can be tested to see if it is skew symmetric using the *Mathematica* function

```
SkewSymmetricQ[l_List?MatrixQ] := (l === -
Transpose[l])
```

The set $o(n)$ of $n \times n$ skew symmetric matrices is a VECTOR SPACE, and the COMMUTATOR

$$[A, B] = AB - BA \tag{3}$$

of two skew symmetric matrices is skew symmetric. Hence, the skew symmetric matrices are a LIE ALGEBRA, which is related to the LIE GROUP of ORTHOGONAL MATRICES. In particular, suppose $A(t)$ is a path of orthogonal matrices through $A(0) = I$, i.e., $A(t)A^t(t) = I$ for all t. The DERIVATIVE at $t = 0$ of both sides must be equal so $dA/dt(0) + dA^t/dt(0) = 0$. That is, the DERIVATIVE of $A(t)$ at the identity must be a skew symmetric matrix.

The EXPONENTIAL MAP of a skew symmetric matrix is an ORTHOGONAL MATRIX.

Skewes Number

The Skewes number (or first Skewes number) is the number Sk_1 above which $\pi(n < \mathrm{Li}(n))$ must fail (assuming that the RIEMANN HYPOTHESIS is true), where $\pi(n)$ is the PRIME COUNTING FUNCTION and $\mathrm{Li}(n)$ is the LOGARITHMIC INTEGRAL. In 1912, Littlewood proved that Sk_1 exists (Hardy 1999, p. 17), and the upper bound

$$\mathrm{Sk}_1 = e^{e^{e^{79}}} \approx 10^{10^{10^{34}}}$$

was subsequently found by Skewes. The Skewes number has since been reduced to $e^{e^{27/4}} \approx 8.185 \times 10^{370}$ by te Riele (1987), although Conway and Guy (1996) claim that the best current limit is 10^{1167}. In 1914, Littlewood proved that the inequality must, in fact, fail infinitely often.

The second Skewes number Sk_2 is the number above which $\pi(n < \mathrm{Li}(n))$ must fail (assuming that the RIEMANN HYPOTHESIS is false). It is much larger than the Skewes number Sk_1,

$$\mathrm{Sk}_2 = 10^{10^{10^{10^3}}}.$$

Skewness

The degree of asymmetry of a distribution. If the distribution has a longer tail less than the maximum, the function has NEGATIVE skewness. Otherwise, it has POSITIVE skewness. Several types of skewness are defined. The FISHER SKEWNESS (the most common type of skewness, usually referred to simply as "the" skewness) is defined by

$$\gamma_1 = \frac{\mu_3}{\mu_2^{3/2}} = \frac{\mu_3}{\sigma^3}, \tag{1}$$

where μ_3 is the third CENTRAL MOMENT, and $\mu_2^{1/2} \equiv \sigma$ is the STANDARD DEVIATION. The following table gives the skewness for a number of common distributions.

distribution	skewness
BERNOULLI DISTRIBUTION	$\frac{1-2p}{\sqrt{p(1-p)}}$
BETA DISTRIBUTION	$\frac{2(b-a)}{(2a+b)}\sqrt{\frac{1+a+b}{ab}}$
BINOMIAL DISTRIBUTION	$\frac{1-2p}{\sqrt{np(1-p)}}$
CHI-SQUARED DISTRIBUTION	$2\sqrt{\frac{2}{r}}$
EXPONENTIAL DISTRIBUTION	2
FISHER-TIPPETT DISTRIBUTION	$\frac{12\sqrt{6}\zeta(3)}{\pi^3}$
F-DISTRIBUTION	$\frac{2(2n+m-2)}{m-6}\sqrt{\frac{2(m-4)}{n(m+n-2)}}$
GAMMA DISTRIBUTION	$\frac{2}{\sqrt{n}}$
GEOMETRIC DISTRIBUTION	$\frac{2-p}{\sqrt{1-p}}$
HALF-NORMAL DISTRIBUTION	$\frac{\sqrt{2}(4-\pi)}{(\pi-2)^{3/2}}$
HYPERGEOMETRIC DISTRIBUTION	$\frac{(m-n)(m+n-2N)}{m+n-2}\sqrt{\frac{m+n-1}{mnN(m+n-N)}}$

LAPLACE DISTRIBUTION	0
LOG NORMAL DISTRIBUTION	$\sqrt{e^{S^2}-1}(2+e^{S^2})$
MAXWELL DISTRIBUTION	$\frac{8}{3}\sqrt{\frac{2}{3\pi}}$
NEGATIVE BINOMIAL DISTRIBUTION	$\frac{2-p}{\sqrt{r(1-p)}}$
NORMAL DISTRIBUTION	0
POISSON DISTRIBUTION	$\nu^{-1/2}$
RAYLEIGH DISTRIBUTION	$(\pi-3)\sqrt{\frac{\pi}{2\left(2-\frac{1}{2}\pi\right)^3}}$
SNEDECOR'S F-DISTRIBUTION	$\frac{2(n+2m-2)}{(n-6)}\sqrt{\frac{2(n-4)}{m(m+n-2)}}$
STUDENT'S T-DISTRIBUTION	0
UNIFORM DISTRIBUTION	0

The PEARSON SKEWNESS is defined by

$$\beta_1 = \left(\frac{\mu^3}{\sigma^3}\right)^2 = \gamma_1^2. \tag{2}$$

The MOMENTAL SKEWNESS is defined by

$$\alpha^{(m)} \equiv \tfrac{1}{2}\gamma_1. \tag{3}$$

The PEARSON MODE SKEWNESS is defined by

$$\frac{[\text{mean}] - [\text{mode}]}{\sigma}. \tag{4}$$

PEARSON'S SKEWNESS COEFFICIENTS are defined by

$$\frac{3[\text{mean}] - [\text{mode}]}{s} \tag{5}$$

and

$$\frac{3[\text{mean}] - [\text{median}]}{s}. \tag{6}$$

The BOWLEY SKEWNESS (also known as QUARTILE SKEWNESS COEFFICIENT) is defined by

$$\frac{(Q_3-Q_2)-(Q_2-Q_1)}{Q_3-Q_1} = \frac{Q_1-2Q_2+Q_3}{Q_3-Q_1}, \tag{7}$$

where the Qs denote the INTERQUARTILE RANGES. The MOMENTAL SKEWNESS is

$$\alpha^{(m)} \equiv \tfrac{1}{2}\gamma = \frac{\mu_3}{2\sigma^3}. \tag{8}$$

An ESTIMATOR for the FISHER SKEWNESS γ_1 is

$$g_1 = \frac{k_3}{k_2^{3/2}}, \tag{9}$$

where the ks are K-STATISTICS. For a normal population with a SAMPLE SIZE of N, the VARIANCE of g_1 is

$$\operatorname{var}(g_1) \approx \frac{6}{N} \tag{10}$$

(Kendall *et al.* 1987).

Sklar's Theorem

Let H be a 2-D distribution function with marginal distribution functions F and G. Then there exists a COPULA C such that

$$H(x,\ y) = C(F(x),\ G(y)).$$

Conversely, for any univariate distribution functions F and G and any COPULA C, the function H is a two-dimensional distribution function with marginals F and G. Furthermore, if F and G are continuous, then C is unique.

Skolem Sequence

A Skolem sequence of order n is a sequence $S = \{s_1, s_2, \ldots, s_{2n}\}$ of $2n$ integers such that

1. For every $k \in \{1, 2, \ldots, n\}$, there exist exactly two elements $s_i, s_j \in S$ such that $s_i = s_j = k$, and
2. If $s_i = s_j = k$ with $i < j$, then $j - i = k$.

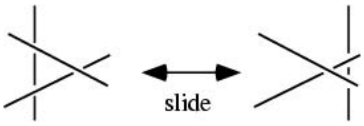
Slice Knot

A knot K in $\mathbb{S}^3 = \partial\mathbb{D}^4$ is a slice knot if it bounds a disk Δ^2 in $\mathbb{D}^4$ which has a tubular neighborhood $\Delta^2 \times \mathbb{D}^2$ whose intersection with $\mathbb{S}^3$ is a tubular neighborhood $K \times \mathbb{D}^2$ for K.



Every ribbon knot is a slice knot, and it is conjectured that every slice knot is a ribbon knot.

Slide Move

The Reidemeister move of type III.

See also Knot Move, Reidemeister Moves

Slide Rule

A mechanical device consisting of a sliding portion and a fixed case, each marked with logarithmic axes. By lining up the ticks, it is possible to do multiplication by taking advantage of the additive property of logarithms. More complicated slide rules also allow the extraction of roots and computation of trigonometric functions.

According to Steinhaus (1983, p. 301), the principle of the slide rule was first enumerated by E. Gunter in 1623, and in 1671, S. Partridge constructed an instrument similar to the modern slide rule. The slide rule was an indispensable tool for scientists and engineers through the 1960s, but the development of the desk calculator (and subsequently pocket calculator) rendered slide rules largely obsolete beginning in the early 1970s.

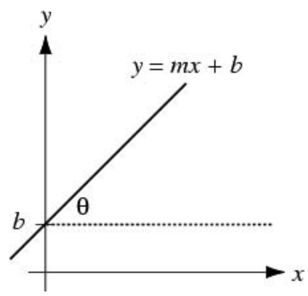
ALMOST PERFECT NUMBER



Slightly Excessive Number

QUASIPERFECT NUMBER

Slip Knot

RUNNING KNOT

Slope

A quantity which gives the inclination of a curve or line with respect to another curve or line. For a LINE in the xy-PLANE making an ANGLE θ with the x-AXIS, the slope m is a constant given by

$$m \equiv \frac{\Delta y}{\Delta x} = \tan\theta, \tag{1}$$

where Δx and Δy are changes in the two coordinates over some distance.

It is meaningless to talk about the slope of a curve in 3-dimensional space unless the slope *with respect to what* is specified.

J. Miller has undertaken a detailed study of the origin of the symbol m to denote slope. The consensus seems to be that it is not known why the letter m was chosen. One high school algebra textbook says the reason for m is unknown, but remarks that it is interesting that the French word for "to climb" is "monter." However, there is no evidence to make any such connection and in fact, Descartes, who was French, did not use m (Miller). Eves (1971) suggests "it just happened."

The earliest known example of the symbol m appearing in print is O'Brien (1844). Salmon (1960) subsequently used the symbols commonly employed today to give the slope-intercept form of a line

$$y = mx + b \tag{2}$$

in his famous treatise published in several editions beginning in 1848. Todhunter (1888) also employed the symbol m, writing the slope-intercept form

$$y = mx + c. \tag{3}$$

However, *Webster's New International Dictionary* (1909) gives the "slope form" as

$$y = sx + b. \tag{4}$$

(Miller).

In Swedish textbooks, the slope-intercept equation is usually written as

$$y = kx + m, \tag{5}$$

where k may derive from "koefficient" in the Swedish word for slope, "riktningskoefficient." In the Netherlands, the equation is commonly written as one of

$$y = ax + b \tag{6}$$

$$y = px + q \tag{7}$$

$$y = mx + n. \tag{8}$$

In Austria, k is used for the slope, and d for the y-intercept (Miller).

PEARLS OF SLUZE

Smale Horseshoe Map

The basic topological operations for constructing an ATTRACTOR consist of stretching (which gives sensitivity to initial conditions) and folding (which gives the attraction). Since trajectories in PHASE SPACE cannot cross, the repeated stretching and folding operations result in an object of great topological complexity.

The Smale horseshoe map consists of a sequence of operations on the unit square. First, stretch by a factor of 2 in the x direction, then compress by $2a$ in the y direction. Then, fold the rectangle and fit it back into the square. Repeating this generates the horseshoe attractor. If one looks at a CROSS SECTION of the final structure, it is seen to correspond to a CANTOR SET.

Small Number

Guy's "STRONG LAW OF SMALL NUMBERS" states that there aren't enough small numbers to meet the many demands made of them. Guy (1988) also gives several interesting and misleading facts about small numbers:

1. 10% of the first 100 numbers are SQUARE NUMBERS.
2. A QUARTER of the numbers < 100 are PRIMES.
3. All numbers less than 10, except for 6, are PRIME POWERS.
4. Half the numbers less than 10 are FIBONACCI NUMBERS.

References

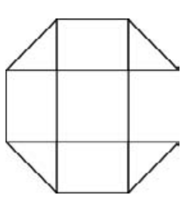
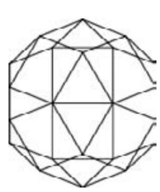
Cundy, H. and Rollett, A. "lpar;Small) Rhombicosidodecahedron. $S_k(n)$." §3.7.11 in *Mathematical Models, 3rd ed.* Stradbroke, England: Tarquin Pub., p. 111, 1989.



Wenninger, M. J. "The Rhombicosidodecahedron." Model 14 in *Polyhedron Models.* Cambridge, England: Cambridge University Press, p. 28, 1989.



Small Rhombicuboctahedron

The 26-faced ARCHIMEDEAN SOLID A_6 consisting of faces $8\{3\}+18\{4\}$. Although this solid is sometimes also called the truncated icosidodecahedron, this name is inappropriate since true TRUNCATION would yield rectangular instead of square faces. It is UNIFORM POLYHEDRON U_{10} and Wenninger model W_{13}. It has SCHLÄFLI SYMBOL $r\{{3 \atop 4}\}$ and WYTHOFF SYMBOL $34\,|\,2$.

Its DUAL POLYHEDRON is the DELTOIDAL ICOSITETRAHEDRON, also called the TRAPEZOIDAL ICOSITETRAHEDRON. The INRADIUS r of the dual, MIDRADIUS ρ of the solid and dual, and CIRCUMRADIUS R of the solid for $a=1$ are

$$r = \tfrac{1}{17}(6+\sqrt{2})\sqrt{5+2\sqrt{2}} = 1.22026\ldots$$

$$\rho = \tfrac{1}{2}\sqrt{4+2\sqrt{2}} = 1.30656\ldots$$

$$R = \tfrac{1}{2}\sqrt{5+2\sqrt{2}} = 1.39896\ldots$$

The distances between the solid center and centroids of the triangular and square faces are

$$r_3 = \tfrac{1}{2}(1+\sqrt{2}) \tag{1}$$

$$r_4 = \tfrac{1}{2}\sqrt{\tfrac{1}{3}(11+6\sqrt{2})}. \tag{2}$$

The SURFACE AREA and VOLUME are

$$S = 18+2\sqrt{3} \tag{3}$$

$$V = \tfrac{1}{3}(12+10\sqrt{2}). \tag{4}$$

The CONVEX HULL of the SMALL CUBICUBOCTAHEDRON is the small rhombicuboctahedron, whose dual is the DELTOIDAL ICOSITETRAHEDRON, so the dual of the SMALL CUBICUBOCTAHEDRON (i.e., the SMALL HEXACRONIC ICOSITETRAHEDRON) is one of the stellations of the DELTOIDAL ICOSITETRAHEDRON (Wenninger 1983, p. 57).

A version of the small rhombicuboctahedron in which the top and bottom halves are rotated with respect to each other is known as the ELONGATED SQUARE GYROBICUPOLA.

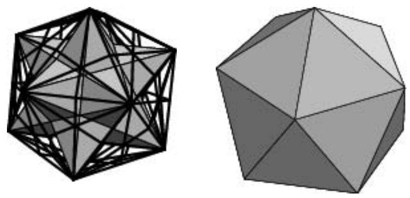
Wenninger, M. J. *Dual Models.* Cambridge, England: Cambridge University Press, p. 84, 1983.

Small Stellated Dodecahedron

One of the KEPLER-POINSOT SOLIDS whose DUAL POLYHEDRON is the GREAT DODECAHEDRON. It is also UNIFORM POLYHEDRON U_{34}, Wenninger model W_{21}, and is the first STELLATION of the DODECAHEDRON (Wenninger 1989). It was originally called the URCHIN by Kepler. The small stellated dodecahedron has SCHLÄFLI SYMBOL $\left\{\frac{5}{2}, 5\right\}$ and WYTHOFF SYMBOL $5|2\ \frac{5}{2}$. It is composed of 12 PENTAGRAMMIC faces. Its faces are $12\left\{\frac{5}{2}\right\}$.



The easiest way to construct a small stellated dodecahedron is by CUMULATION, i.e., building twelve PENTAGONAL PYRAMIDS and attaching them to the faces of a DODECAHEDRON. The height of the pyramids for a small stellated dodecahedron built on a DODECAHEDRON of unit edge length is $\sqrt{\frac{1}{5}(5+2\sqrt{5})}$. The CIRCUMRADIUS of the small stellated dodecahedron with *pentagrammic* edge length $a=1$ is

$$R=\tfrac{1}{2}\,5^{1/4}\phi^{-1/2}=\tfrac{1}{4}\,5^{1/4}\sqrt{2\left(\sqrt{5}-1\right)}.$$

Schläfli (1901, p. 134) did not recognize the small stellated dodecahedron because it, like the GREAT DODECAHEDRON, satisfies

$$N_0-N_1+N_2=12-30+12=-6, \qquad (1)$$

where N_0 is the number of vertices, N_1 the number of edges, and N_2 the number of faces (Coxeter 1973, p. 172), thus violating the POLYHEDRAL FORMULA.

The CONVEX HULL of the small stellated dodecahedron is a regular DODECAHEDRON and the dual of the DODECAHEDRON is the ICOSAHEDRON, so the dual of the small stellated dodecahedron is one of the ICOSAHEDRON STELLATIONS (Wenninger 1983, p. 40)

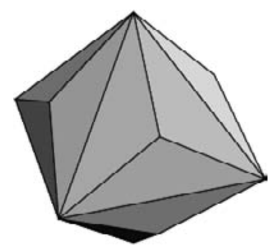
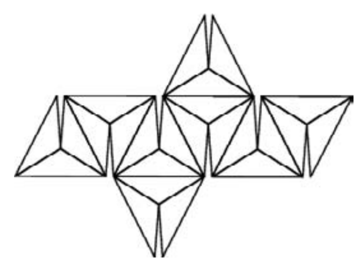
Small Stellated Triacontahedron

MEDIAL RHOMBIC TRIACONTAHEDRON

Small Stellated Truncated Dodecahedron



The UNIFORM POLYHEDRON U_{58} also called the QUASITRUNCATED SMALL STELLATED DODECAHEDRON whose DUAL POLYHEDRON is the GREAT PENTAKIS DODECAHEDRON. It has SCHLÄFLI SYMBOL t' $\left\{\frac{5}{2}, 5\right\}$ and WYTHOFF SYMBOL $2\ 5\left|\frac{5}{3}\right.$. Its faces are $12\{5\}+12\left\{\frac{10}{3}\right\}$. Its CIRCUMRADIUS with $a=1$ is



$$R=\tfrac{1}{4}\sqrt{34-10\sqrt{5}}.$$

References

Wenninger, M. J. *Polyhedron Models.* Cambridge, England: Cambridge University Press, p. 151, 1971.

Small Triakis Octahedron

The 24-faced DUAL POLYHEDRON of the TRUNCATED CUBE A_9 and Wenninger dual W_8. It can be constructed by CUMULATION of a unit edge-length OCTAHEDRON by a pyramid with height $\sqrt{3}-\frac{2}{3}\sqrt{6}$. For a TRUNCATED CUBE of unit side length the dual has edges of lengths

$$s_1=2 \tag{1}$$

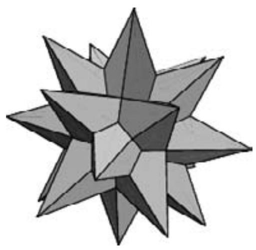
$$s_2=2+\sqrt{2}. \tag{2}$$

Normalizing so that $s_1=1$, the resulting small triakis octahedron has SURFACE AREA and VOLUME

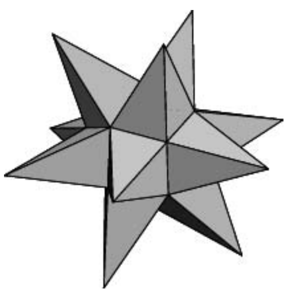
$$S=3\sqrt{7+4\sqrt{2}} \tag{3}$$

$$V=\tfrac{1}{2}\left(3+2\sqrt{2}\right). \tag{4}$$

See also ARCHIMEDEAN DUAL, ARCHIMEDEAN SOLID, GREAT TRIAKIS OCTAHEDRON, ICOSITETRAHEDRON,



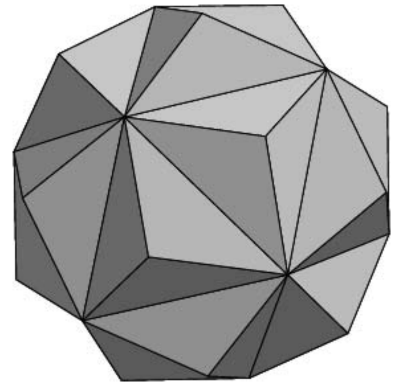
SMALL TRIAKIS OCTAHEDRON STELLATIONS, TRUNCATED CUBE



References

Wenninger, M. J. *Dual Models.* Cambridge, England: Cambridge University Press, p. 7, 1983.

Small Triakis Octahedron Stellations



R. Whorf found that there are probably several thousand stellations of the small triakis octahedron (Wenninger 1983, p. 36). In particular, the CONVEX HULLS of the GREAT CUBICUBOCTAHEDRON U_{14}, the Archimedean GREAT RHOMBICUBOCTAHEDRON $A_3 = U_{17}$, and GREAT RHOMBIHEXAHEDRON U_{21} are all the Archimedean TRUNCATED CUBE A_9, whose dual is the SMALL TRIAKIS OCTAHEDRON, so the duals of these solids (i.e., the GREAT HEXACRONIC ICOSITETRAHEDRON, GREAT DELTOIDAL ICOSITETRAHEDRON, and GREAT RHOMBIHEXAHEDRON) are all stellations of the small triakis octahedron (Wenninger 1983, p. 57).

References

Wenninger, M. J. *Dual Models.* Cambridge, England: Cambridge University Press, pp. 36, 38, and 57–58, 1983.

Small Triambic Icosahedron

The DUAL POLYHEDRON of the SMALL DITRIGONAL ICOSIDODECAHEDRON U_{30} and Wenninger model W_{70}. It can be constructed by CUMULATION of a unit edge-length ICOSAHEDRON by a pyramid with height $\sqrt{15}/15$. Wenninger (1989, p. 49) calls this solid the triakis octahedron (which is a term more commonly used for the dual of one of the Archimedean solids).

The CONVEX HULL of the SMALL DITRIGONAL ICOSIDODECAHEDRON is a regular DODECAHEDRON, whose dual is the ICOSAHEDRON, so the dual of the SMALL DITRIGONAL ICOSIDODECAHEDRON (the small triambic icosahedron) is one of the ICOSAHEDRON STELLATIONS (Wenninger 1983, p. 42).

Small World Problem

The small world problem asks for the probability that two people picked at random have at least one acquaintance in common.

See also BIRTHDAY PROBLEM

Smarandache Ceil Function

A SMARANDACHE-like function which is defined where $S_k(n)$ is defined as the smallest integer for which $n|S_k(n)^k$. The Smarandache $S_k(n)$ function can therefore be obtained by replacing any factors which are kth powers in n by their k roots.

$$S_k(n) = \frac{n}{M_k(n)},$$

where $M_k(n)$ is the number of solutions to $x^k \equiv 0 \pmod{n}$.

The functions $S_k(n)$ for $k = 2, 3, ..., 6$ for values such that $S_k(n) \neq n$ are tabulated by Begay (1997). The following tables gives $S_k(n)$ for small k and $n = 1, 2, ...$.

k	Sloane	$S_k(n)$
1	A000027	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, ...

Smarandache Constants

"The" Smarandache constant is the smallest solution to the generalized ANDRICA'S CONJECTURE, $x \approx 0.567148$.

The first Smarandache constant is defined as

$$S_1 \equiv \sum_{n=2}^{\infty} \frac{1}{[S(n)]!} > 1.093111, \tag{1}$$

where $S(n)$ is the SMARANDACHE FUNCTION. Cojocaru and Cojocaru (1996a) prove that S_1 exists and is bounded by $0.717 < S_1 < 1.253$. The lower limit given above is obtained by taking 40,000 terms of the sum.

Cojocaru and Cojocaru (1996b) prove that the second Smarandache constant

$$S_2 \equiv \sum_{n=2}^{\infty} \frac{S(n)}{n!} \approx 1.71400629359162 \tag{2}$$

is an IRRATIONAL NUMBER.

Cojocaru and Cojocaru (1996c) prove that the series

$$S_3 \equiv \sum_{n=2}^{\infty} \frac{1}{\prod_{i=2}^{n} S(i))} \approx 0.719960700043708 \tag{3}$$

converges to a number $0.71 < S_3 < 1.01$, and that

$$S_4(a) \equiv \sum_{n=2}^{\infty} \frac{n^a}{\prod_{i=2}^{n} S(i)} \tag{4}$$

converges for a fixed REAL NUMBER $a \geq 1$. The values for small a are

$$S_4(1) \approx 1.72875760530223 \tag{5}$$

$$S_4(2) \approx 4.50251200619297 \tag{6}$$

$$S_4(3) \approx 13.0111441949445 \tag{7}$$

$$S_4(4) \approx 42.4818449849626 \tag{8}$$

$$S_4(5) \approx 158.105463729329. \tag{9}$$

Sandor (1997) shows that the series

$$S_5 \equiv \sum_{n=1}^{\infty} \frac{(-1)^{n-1} S(n)}{n!} \tag{10}$$

converges to an IRRATIONAL. Burton (1995) and Dumitrescu and Seleacu (1996) show that the series

$$S_6 \equiv \sum_{n=2}^{\infty} \frac{S(n)}{(n+1)!} \tag{11}$$

converges. Dumitrescu and Seleacu (1996) show that the series

$$S_7 \equiv \sum_{n=r}^{\infty} \frac{S(n)}{(n+r)!} \tag{12}$$

and

$$S_8 \equiv \sum_{n=r}^{\infty} \frac{S(n)}{(n-r)!} \tag{13}$$

converge for r a natural number (which must be nonzero in the latter case). Dumitrescu and Seleacu (1996) show that

$$S_9 \equiv \sum_{n=1}^{\infty} \frac{1}{\sum_{i=2}^{n} \frac{S(i)}{i!}} \tag{14}$$

converges. Burton (1995) and Dumitrescu and Seleacu (1996) show that the series

$$S_{10} \equiv \sum_{n=2}^{\infty} \frac{1}{[S(n)]^a \sqrt{S(n)!}} \tag{15}$$

and

$$S_{11} \equiv \sum_{n=2}^{\infty} \frac{1}{[S(n)]^a \sqrt{[S(n)+1]!}} \tag{16}$$

converge for $a > 1$.

Smarandache Function

The smallest value $S(n)$ for a given n for which $n|S(n)!$ (n divides $S(n)$ FACTORIAL). For example, the number 8 does not divide 1!, 2!, 3!, but does divide $4! = 4 \cdot 3 \cdot 2 \cdot 1 = 8 \cdot 3$, so $S(8) = 4$. For a PRIME p, $S(p) = p$, and for an EVEN PERFECT NUMBER r, $S(r)$ is PRIME (Ashbacher 1997). Sloane places the restriction $S(n) > 0$, while Ashbacher (1995) and Russo (2000, p. 4) take $S(n) \geq 0$.

The Smarandache numbers for $n = 1, 2, ...$ are 1, 2, 3, 4, 5, 3, 7, 4, 6, 5, 11, ... (Sloane's A002034; but, depending on the convention, $S(1)$ may equal either 0 or 1). Letting $a(n)$ denote the smallest value of n for which $S(n) = 1, 2, ...$, then $a(n)$ is given by 1, 2, 3, 4, 5, 9, 7, 32, 27, 25, 11, 243, ... (Sloane's A046021). Some values of $S(n)$ first occur only for very large n, for example, $S(59, 049) = 24$, $S(177, 147) = 27$, $S(134, 217, 728) = 30$, $S(43, 046, 721) = 36$, and $S(9, 765, 625) = 45$. D. Wilson points out that if we let

$$I(n, p) = \frac{n - \sum(n, p)}{p - 1},$$

be the power of the PRIME p in $n!$, where $\Sigma(n, p)$ is the sum of the base-p digits of n, then it follows that

$$a(n) = \min p^{I(n-1, p)+1},$$

where the minimum is taken over the PRIMES p dividing n. This minimum appears to always be achieved when p is the GREATEST PRIME FACTOR of n. If $n = 2^{k-1}(2^k - 1)$ is an even PERFECT NUMBER (i.e., $2^k - 1$ is prime), then $S(n) = p$ (Ruiz 1999a). If p is a prime number and $n \geq 2$ an integer, then $S(p^{p^n}) = p^{n+1} - p^n + p$. (Ruiz 1999b).

The incrementally largest values of $S(n)$ are 1, 2, 3, 4, 5, 7, 11, 13, 17, 19, 23, 29, ... (Sloane's A046022), which occur for n = 1, 2, 3, 4, 5, 7, 11, 13, 17, 19, 23, 29, ... (Sloane's A046023), i.e., the values where $S(n) = n$.

Tutescu (1996) conjectures that the DIOPHANTINE EQUATION $S(n) = S(n+1)$ has no solution.

Smarandache Near-to-Primorial Function

$SNTP(n)$ is the smallest PRIME such that $p\#-1$, $p\#$, or $p\#+1$ is divisible by n, where $p\#$ is the PRIMORIAL of p. Ashbacher (1996) shows that $SNTP(n)$ only exists

1. If there are no square or higher powers in the factorization of n, or
2. If there exists a PRIME $q<p$ such that $n|(q\#\pm 1)$, where p is the smallest power contained in the factorization of n.

Therefore, $SNTP(n)$ does not exist for the SQUAREFUL numbers $n=4$, 8, 9, 12, 16, 18, 20, 24, 25, 27, 28, ... (Sloane's A013929). The first few values of $SNTP(n)$, where defined, are 2, 2, 2, 3, 3, 3, 5, 7, ... (Sloane's A046026).

Smarandache Paradox

Let A be some attribute (e.g., possible, present, perfect, etc.). If all is A, then the non-A must also be A. For example, "All is possible, the impossible too," and "Nothing is perfect, not even the perfect."

Smarandache Sequences

Smarandache sequences are any of a number of simply generated INTEGER SEQUENCES resembling those considered in published works by Smarandache such as the CONSECUTIVE NUMBER SEQUENCES and EUCLID NUMBERS (Iacobescu 1997). Some other "Smarandache" sequences are given below.

1. The concatenation of n copies of the INTEGER n: 1, 22, 333, 4444, 55555, ... (Sloane's A000461; Marimutha 1997),
2. The concatenation of the first n FIBONACCI NUMBERS: 1, 11, 112, 1123, 11235, ... (Sloane's A019523; Marimutha 1997),
3. The smallest number that is the sum of squares of *two* distinct earlier terms: 1, 2, 5, 26, 29, 677, ... (Sloane's A008318, Bencze 1997),
4. The smallest number that is the sum of squares of any number of distinct earlier terms: 1, 1, 2, 4, 5, 6, 16, 17, ... (Sloane's A008319, Bencze 1997),
5. The smallest number that is *not* the sum of squares of *two* distinct earlier terms: 1, 2, 3, 4, 6, 7, 8, 9, 11, ... (Sloane's A008320, Bencze 1997),
6. The smallest number that is *not* the sum of squares of any number of distinct earlier terms: 1, 2, 3, 6, 7, 8, 11, ... (Sloane's A008321, Bencze 1997),
7. The smallest number that is a sum of cubes of *two* distinct earlier terms: 1, 2, 9, 730, 737, ... (Sloane's A008322, Bencze 1997),
8. The smallest number that is a sum of cubes of any number of distinct earlier terms: 1, 1, 2, 8, 9, 10, 512, 513, 514, ... (Sloane's A019511, Bencze 1997),
9. The smallest number that is *not* a sum of cubes of *two* distinct earlier terms: 1, 2, 3, 4, 5, 6, 7, 8, 10, ... (Sloane's A031980, Bencze 1997),
10. The smallest number that is *not* a sum of cubes of any number of distinct earlier terms: 1, 2, 3, 4, 5, 6, 7, 10, 11, ... (Sloane's A031981, Bencze 1997),
11. The number of PARTITIONS of a number $n=1$, 2, ... into SQUARE NUMBERS: 1, 1, 1, 1, 2, 2, 2, 2, 3, 4, 4, 4, 5, 6, 6, 6, 8, 9, 10, 10, 12, 13, ... (Sloane's A001156, Iacobescu 1997),
12. The number of PARTITIONS of a number $n=1$, 2, ... into CUBIC NUMBERS: 1, 1, 1, 1, 1, 1, 1, 1, 2, 2,

2, 2, 2, 2, 2, 2, 3, 3, 3, 3, 3, 3, 3, ... (Sloane's A003108, Iacobescu 1997),
13. Two copies of the first n POSITIVE INTEGERS: 11, 1212, 123123, 12341234, ... (Sloane's A019524, Iacobescu 1997),
14. Numbers written in base of triangular numbers: 1, 2, 10, 11, 12, 100, 101, 102, 110, 1000, 1001, 1002, ... (Sloane's A000462, Iacobescu 1997),
15. Numbers written in base of double factorial numbers: 1, 10, 100, 101, 110, 200, 201, 1000, 1001, 1010, ... (Sloane's A019513, Iacobescu 1997),
16. Sequences starting with terms $\{a_1, a_2\}$ which contain no three-term arithmetic progressions starting with $\{1, 2\}$: 1, 2, 4, 5, 10, 11, 13, 14, 28, ... (Sloane's A003278, Iacobescu 1997, Mudge 1997, Weisstein),
17. Numbers OF THE FORM $\{n!\}^2+1$: 2, 5, 37, 577, 14401, 518401, 25401601, 1625702401, 131681894401, ... (Sloane's A020549, Iacobescu 1997),
18. Numbers OF THE FORM $\{n!\}^3+1$: 2, 9, 217, 13825, 1728001, 373248001, 128024064001, ... (Sloane's A019514, Iacobescu 1997),
19. Numbers OF THE FORM $1+1!2!3!\cdots n!$: 2, 3, 13, 289, 34561, 24883201, 125411328001, 5056584744960001, ... (Sloane's A019515, Iacobescu 1997),
20. Sequences starting with terms $\{a_1, a_2\}$ which contain no three-term geometric progressions starting with $\{1, 2\}$: 1, 2, 3, 5, 6, 7, 8, 10, 11, 13, 14, 15, 16, ... (Sloane's A000452, Iacobescu 1997),
21. Numbers repeating the digit 1 p_n times, where p_n is the nth prime: 11, 111, 11111, 1111111, ... (Sloane's A031974, Iacobescu 1997). These are a subset of the REPUNITS,
22. Integers with all 2s, 3s, 5s, and 7s (prime digits) removed: 1, 4, 6, 8, 9, 10, 11, 1, 1, 14, 1, 16, 1, 18, 19, 0, ... (Sloane's A019516, Iacobescu 1997),
23. Integers with all 0s, 1s, 4s, and 9s (square digits) removed: 2, 3, 5, 6, 7, 8, 2, 3, 5, 6, 7, 8, 2, 2, 22, 23, ... (Sloane's A031976, Iacobescu 1997).
24. (Smarandache-Fibonacci triples) Integers n such that $S(n)=S(n-1)+S(n-2)$, where $S(k)$ is the SMARANDACHE FUNCTION: 3, 11, 121, 4902, 26245, ... (Sloane's A015047; Aschbacher and Mudge 1995; Ibstedt 1997, pp. 19–23; Begay 1997). The largest known is 19,448,047,080,036,
25. (Smarandache-Radu triplets) Integers n such that there are no primes between the smaller and larger of $S(n)$ and $S(n+1)$: 224, 2057, 265225, ... (Sloane's A015048; Radu 1994/1995, Begay 1997, Ibstedt 1997). The largest known is 270,329,975,921,205,253,634,707,051,822,848,570-,391,313,
26. (Smarandache crescendo sequence): Integers obtained by concatenating strings of the first $n+1$ integers for $n=0$, 1, 2, ...: 1, 1, 2, 1, 2, 3, 1, 2, 3, 4, ... (Sloane's A002260; Brown 1997, Brown and Castillo 1997). The nth term is given by $n-m(m+1)/2+1$, where $m=\lfloor(\sqrt{8n+1}-1)/2\rfloor$, with $\lfloor x\rfloor$ the FLOOR FUNCTION (Hamel 1997),
27. (Smarandache descrescendo sequence): Integers obtained by concatenating strings of the first n integers for $n=\ldots$, 2, 1: 1, 2, 1, 3, 2, 1, 4, 3, 2, 1, ... (Sloane's A004736; Smarandache 1997, Brown 1997),
28. (Smarandache crescendo pyramidal sequence, a.k.a. Smarandache descrescendo symmetric sequence): Integers obtained by concatenating strings of rising and falling integers: 1, 1, 2, 1, 1, 2, 3, 2, 1, 1, 2, 3, 4, 3, 2, 1, ... (Sloane's A004737; Brown 1997, Brown and Castillo 1997, Smarandache 1997),
29. (Smarandache descrescendo pyramidal sequence): Integers obtained by concatenating strings of falling and rising integers: 1, 2, 1, 2, 3, 2, 1, 2, 3, 4, 3, 2, 1, 2, 3, 4, ... (Sloane's A004738; Brown 1997),
30. (Smarandache crescendo symmetric sequence): 1, 1, 1, 2, 2, 1, 1, 2, 3, 3, 2, 1, ... (Sloane's A004739, Brown 1997, Smarandache 1997),
31. (Smarandache permutation sequence): Numbers obtained by concatenating sequences of increasing length of increasing ODD NUMBERS and decreasing EVEN NUMBERS: 1, 2, 1, 3, 4, 2, 1, 3, 5, 6, 4, 2, ... (Sloane's A004741; Brown 1997, Brown and Castillo 1997),
32. (Smarandache pierced chain sequence): Numbers OF THE FORM

$$c(n)=101\underbrace{\underbrace{0101}\cdots\underbrace{0101}}_{n}$$

for $n=0$, 1, ...: 101, 1010101, 10101010101, ... (Sloane's A031982; Ashbacher 1997). In addition, $c(n)/101$ contains no PRIMES (Ashbacher 1997),
33. (Smarandache symmetric sequence): 1, 11, 121, 1221, 12321, 123321, ... (Sloane's A007907; Smarandache 1993, Dumitrescu and Seleacu 1994, sequence 3; Mudge 1995),
34. (Smarandache square-digital sequence): square numbers all of whose digits are also squares: 1, 4, 9, 49, 100, 144, ... (Sloane's A019544; Mudge 1997),
35. (Square-digits): numbers composed of digits which are squares: 0, 1, 4, 9, 10, 11, 14, 19, 40, 41, ... (Sloane's A046030),
36. (Cube-digits): numbers composed of digits which are cubes: 1, 8, 10, 11, 18, 80, 81, 88, 100, 101, ... (Sloane's A046031),
37. (Smarandache cube-digital sequence): cube-digit numbers which are themselves cubes: 1, 8,

1000, 8000, 1000000, ... (Sloane's A019545; Mudge 1997),

38. (Prime-digits): numbers composed of digits which are primes: 2, 3, 5, 7, 22, 23, 25, 27, 32, 33, 35, ... (Sloane's A046034),

39. (Smarandache prime-digital sequence): prime-digit numbers which are themselves prime: 2, 3, 5, 7, 23, 37, 53, ... (Sloane's A019546; Smith 1996, Mudge 1997).

40. (Smarandache deconstructive sequence): integers constructed by sequentially repeating the digits 1–9 in the following way: 1, 23, 456, 7891, 23456, 789123, 4567891, ... (Sloane's A007923; Smarandache 1993, Kashihara 1996, Ashbacher, Atanassov 1999ab). Of these, 23, 4567891, 23456789, 1234567891, ... (Sloane's A050234) are prime (Kashihara 1996, Ashbacher).

Smarandache-Kurepa Function

Given the sum-of-factorials function

$$\sum(n) = \sum_{k=1}^{n} k!,$$

SK(p) for p PRIME is the smallest integer n such that $p|1+\Sigma(n-1)$. The first few known values of SK(p) are 2, 4, 6, 6, 5, 7, 7, 12, 22, 16, 55, 54, 42, 24, ... for $p = 2$, 5, 7, 11, 17, 19, 23, 31, 37, 41, 61, 71, 73, 89, ... The function SK(p) doe not exists for $p = 3$, 13, 29, 43, 47, 53, 67, 79, 83, ...

Smarandache-Wagstaff Function

Given the sum-of-FACTORIALS function

$$\sum(n) = \sum_{k=1}^{n} k!,$$

$SW(p)$ is the smallest integer for p PRIME such that $\Sigma[SW(p)]$ is divisible by p. If $p \nmid \Sigma(n)$ for all $n < p$, then p never divides any sum for all n. Therefore, the values $SW(p)$ do not exist for 2, 5, 7, 13, 19, 31, ... (Sloane's A056985).

The function is defined for $p = 3$, 11, 17, 23, 29, 37, 41, 43, 53, 67, 73, 79, 97, ... (Sloane's A056983), with corresponding values 2, 4, 5, 12, 19, 24, 32, 19, 20, 20, 20, 7, 57, 6, ... (Sloane's A056985).

Smith Brothers

Consecutive SMITH NUMBERS. The first few Smith brothers are (728, 729), (2964, 2965), (3864, 3865), (4959, 4960), ... (Sloane's A050219 and A050220).

Smith Conjecture

The set of fixed points which do not move as a KNOT is transformed into itself is not a KNOT. The conjecture was proved in 1978 (Morgan and Bass 1984). According to Morgan and Bass (1984), the Smith conjecture stands in the first rank of mathematical problems when measured by the amount and depth of new mathematics required to solve it.

The generalized Smith conjecture states considers $\mathbb{S}^{n-2}$ to be a piecewise linear $(n-2)$-dimensional sphere in $\mathbb{S}^n$, and M^n the k-fold cyclic covering of $\mathbb{S}^n$ branched along S^{n-2}, and asks if S^{n-2} is unknotted if M^n is an $\mathbb{S}^n$ (Hartley 1983). This conjecture is true for $n \leq 3$, and false for $n \geq 4$, with counterexamples in the latter case provided by Giffen (1966), Gordon (1974), and Sumners (1975).

Smith Normal Form

Let A be an $n \times n$ MATRIX over a FIELD F. Using the three ELEMENTARY ROW AND COLUMN OPERATIONS over elements in the field, the $n \times n$ matrix $x\mathsf{I} - \mathsf{A}$ with entries from $F[x]$ can be put into the diagonal form

$$\begin{bmatrix} 1 & 0 & \cdots & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & \ddots & 0 & 0 & 0 & 0 & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & a_1(x) & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & a_2(x) & 0 & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & a_m(x) \end{bmatrix}.$$

called the Smith normal form, which that $a_1(x)$, $a_2(x)$, ..., $a_m(x)$ are monic nonzero elements of $F[x]$ with degrees at least one and satisfying $a_1(x) \times |a_2(x)| \ldots |a_m(x)|$ (Dummit and Foote 1998, pp. 390–391 and 414). The elements $a_i(x)$ are then called the INVARIANT FACTORS of A.

Smith Number

A COMPOSITE NUMBER the SUM of whose DIGITS is the sum of the DIGITS of its PRIME FACTORS (excluding 1). (The PRIMES are excluded since they trivially satisfy this condition). One example of a Smith number is the BEAST NUMBER

$$666 = 2 \cdot 3 \cdot 3 \cdot 37,$$

since

$$6 + 6 + 6 = 2 + 3 + 3 + (3 + 7) = 18.$$

Another Smith number is

$$4937775 = 3 \cdot 5 \cdot 5 \cdot 65837,$$

since

$$4 + 9 + 3 + 7 + 7 + 7 + 5$$
$$= 3 + 5 + 5 + (6 + 5 + 8 + 3 + 7) = 42.$$

The first few Smith numbers are 4, 22, 27, 58, 85, 94, 121, 166, 202, 265, 274, 319, 346, ... (Sloane's A006753). The corresponding digits sums are 4, 4, 9, 13, 13, 13, 4, 13, 4, 13, 13, 13, 13, ... (Sloane's A050218) McDaniel (1987a) showed that there are an infinite number of Smith numbers.

A generalized k-Smith number can also be defined as a number m satisfying $S_p(m) = kS(m)$, where $S_p(m)$ is the sum of the digits of m's prime factors and $S(m)$ is the usual sum of m's digits. The following table gives the first few k-Smith numbers for $k \geq 2$.

k	Sloane	k-Smith numbers
2	A050224	88, 169, 286, 484, 598, 682, 808, 844, 897, ...
3	A050225	6969, 19998, 36399, 39693, 66099, 69663, ...

A Smith number can be constructed from every factored REPUNIT R_n (Hoffman 1998, pp. 205–206). The largest known Smith number is

$$9 \times R_{1031} \left(10^{4594} + 3 \times 10^{2297} + 1\right)^{1476} \times 10^{3913210}.$$

Smith's Markov Process Theorem

Consider

$$P_2(y_1,\ t_1|y_3,\ t_3) = \int P_2(y_1,\ t_1|y_2,\ t_2) P_3(y_1,\ t_1;\ y_2,\ t_2|y_3,\ t_3)\, dy_2. \quad (1)$$

If the probability distribution is governed by a MARKOV PROCESS, then

$$P_3(y_1,\ t_1;\ y_2,\ t_2|y_3,\ t_3) = P_2(y_2,\ t_2|y_3,\ t_3) = P_2(y_2|y_3,\ t_3 - t_2). \quad (2)$$

Assuming no time dependence, so $t_1 \equiv 0$,

$$P_2(y_1|y_3,\ t_3) = \int P_2(y_1|y_2, t_2) P_2(y_2|y_3,\ t_3 - t_2)\, dy_2. \quad (3)$$

See also MARKOV PROCESS

Smith's Network Theorem

In a NETWORK with three EDGES at each VERTEX, the number of HAMILTONIAN CIRCUITS through a specified EDGE is 0 or EVEN.

See also EDGE (GRAPH), HAMILTONIAN CIRCUIT, NETWORK

Smooth Function

A smooth function is a function that has continuous second-order derivatives over some domain. A function can therefore be said to be smooth over a restricted interval such as (a, b) or $[a, b]$.

See also CONTINUOUS FUNCTION, DERIVATIVE

Smooth Manifold

Another word for a C^∞ (infinitely differentiable) MANIFOLD. A smooth manifold is a TOPOLOGICAL MANIFOLD together with its "functional structure" (Bredon 1995) and so differs from a TOPOLOGICAL MANIFOLD because the notion of differentiability exists on it. Every smooth manifold is a TOPOLOGICAL MANIFOLD, but not necessarily vice versa. (The first nonsmooth TOPOLOGICAL MANIFOLD occurs in 4-D.) In 1959, Milnor showed that a 7-D HYPERSPHERE can be made into a smooth manifold in 28 ways.

See also DIFFERENTIABLE MANIFOLD, HYPERSPHERE, MANIFOLD, TOPOLOGICAL MANIFOLD

References

Bredon, G. E. *Topology & Geometry.* New York: Springer-Verlag, p. 69, 1995.

Smooth Number

An INTEGER is k-smooth if it has no PRIME FACTORS $> k$. The following table gives the first few k-smooth numbers for small k. Berndt (1994, p. 52) called the 7-smooth numbers "highly composite numbers."

k	Sloane	k-smooth numbers
2	A000079	1, 2, 4, 8, 16, 32, 64, 128, 256, 512, ...
3	A003586	1, 2, 3, 4, 6, 8, 9, 12, 16, 18, 24, ...
5	A051037	1, 2, 3, 4, 5, 6, 8, 9, 10, 12, 15, 16, ...
7	A002473	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 14, 15, ...
11	A051038	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, ...

The probability that a random POSITIVE INTEGER $\leq n$ is k-smooth is $\psi(n, k)/n$, where $\psi(n, k)$ is the number of k-smooth numbers $\leq n$. This fact is important in application of Kraitchik's extension of FERMAT'S FACTORIZATION METHOD because it is related to the number of random numbers which must be examined to find a suitable subset whose product is a square.

Since about $\pi(k)$ k-smooth numbers must be found (where $\pi(k)$ is the PRIME COUNTING FUNCTION), the number of random numbers which must be examined is about $\pi(k)n/\psi(n, k)$. But because it takes about $\pi(k)$ steps to determine if a number is k-smooth using TRIAL DIVISION, the expected number of steps needed to find a subset of numbers whose product is a square is $\sim [\pi(k)]^2 n/\psi(n, k)$ (Pomerance 1996). Canfield *et al.* (1983) showed that this function is minimized when

$$k \sim \exp\left(\tfrac{1}{2}\sqrt{\ln n \ln \ln n}\right)$$

and that the minimum value is about

$$\exp\left(2\sqrt{\ln n \ln \ln n}\right).$$

In the CONTINUED FRACTION FACTORIZATION ALGORITHM, n can be taken as $2\sqrt{n}$, but in FERMAT'S FACTORIZATION METHOD, it is $n^{1/2+\epsilon}$. k is an estimate for the largest PRIME in the FACTOR BASE (Pomerance 1996).

Smooth Structure

A smooth structure on a TOPOLOGICAL MANIFOLD (also called a differentiable structure) is given by a smooth ATLAS of coordinate charts, i.e., the TRANSITION FUNCTIONS between the coordinate charts are C^∞ smooth. A manifold with a smooth structure is called a DIFFERENTIABLE MANIFOLD or a SMOOTH MANIFOLD.

A smooth structure is used to define DIFFERENTIABILITY for real-valued functions on a manifold. This extends to a notion of when a map between two differentiable manifolds is smooth, and naturally to the definition of a DIFFEOMORPHISM. In addition, the smooth structure is used to define TANGENT VECTORS, the collection of which is the TANGENT BUNDLE.

Two smooth structures are considered equivalent if there is a HOMEOMORPHISM of the manifold which pulls back one atlas to an atlas compatible to the other one, i.e., a DIFFEOMORPHISM. For instance, any two smooth structures on the circle $\mathbb{S}^1$ are equivalent, as can be seen by integration.

It is surprising that some manifolds admit more than one smooth structure. The first such example was an EXOTIC SPHERE of $\mathbb{S}^7$, the 7-dimensional HYPERSPHERE, found by Milnor (1956) using the calculus of OCTONIONS. In the 1980s, several mathematicians, including Casson, Freedman, and Donaldson, showed that 4-dimensional Euclidean space $\mathbb{R}^4$ has smooth structures that are distinct from the standard structure. These are called EXOTIC R4, and some of their techniques involve DONALDSON THEORY.

Another approach to smooth structures is through SHEAF theory. Notice that a coordinate chart for an n-dimensional manifold is really an ordered collection of n continuous functions. Whenever two coordinate charts overlap on the manifold, the functions from one chart are infinitely differentiable with respect to those from the other chart. The collection of compa-

tible real-valued continuous functions defines the sheaf of smooth functions. Conversely, one can define a smooth structure to be defined by a subsheaf of continuous functions which satisfies the mutually differentiable condition.

Smooth Surface

A surface PARAMETERIZED in variables u and v is called smooth if the TANGENT VECTORS in the u and v directions satisfy

$$\mathbf{T}_u + \mathbf{T}_v \neq 0,$$

where $\mathbf{A} \times \mathbf{B}$ is a CROSS PRODUCT.

Smoothing

The modification of a set of data to make it smooth and nearly continuous and remove or diminish outlying points.

sn

JACOBI ELLIPTIC FUNCTIONS

Snake

A simple circuit in the d-HYPERCUBE which has no chords (i.e., for which all snake edges are edges of the HYPERCUBE). Klee (1970) asked for the maximum length $s(d)$ of a d-snake. Klee (1970) gave the bounds

$$\frac{7}{4(d-1)} \leq \frac{s(d)}{2^d}\,\frac{1}{2} - \frac{1+12/2^{-d}}{7d(d-1)^2+2} \tag{1}$$

for $d \geq 6$ (Danzer and Klee 1967, Douglas 1969), as well as numerous references. Abbott and Katchalski (1988) show

$$s(d) \geq 77 \cdot 2^{d-8}, \tag{2}$$

and Snevily (1994) showed that

$$s(d) \leq 2^{d-1}\left(1 - \frac{1}{20d-41}\right) \tag{3}$$

for $d \leq 12$, and conjectured

$$s(d) \leq 3 \cdot 2^{d-3} + 2 \tag{4}$$

for $d \leq 5$. The first few values for $s(d)$ for $d = 1, 2, \ldots$, are 2, 4, 6, 8, 14, 26, ... (Sloane's A000937).

Snedecor's F-Distribution

If a random variable X has a CHI-SQUARED DISTRIBUTION with m degrees of freedom (χ_m^2) and a random variable Y has a CHI-SQUARED DISTRIBUTION with n degrees of freedom (χ_n^2), and X and Y are independent, then

$$F \equiv \frac{X/m}{Y/n} \tag{1}$$

is distributed as Snedecor's F-distribution with m and n degrees of freedom

$$f(F(m,\ n)) = \frac{\Gamma\left(\frac{m+n}{2}\right)\left(\frac{m}{n}\right)^{m/2} F^{(m-2)/2}}{\Gamma\left(\frac{m}{2}\right)\Gamma\left(\frac{n}{2}\right)\left(1+\frac{m}{n}F\right)^{(m+2)/2}} \tag{2}$$

for $0 < F < \infty$. The RAW MOMENTS are

$$\mu_1' = \frac{n}{n-2} \tag{3}$$

$$\mu_2' = \frac{n^2(m+2)}{m(n-2)(n-4)} \tag{4}$$

$$\mu_3' = \frac{n^3(m+2)(m+4)}{m^2(n-2)(n-4)(n-6)} \tag{5}$$

$$\mu_4' = \frac{n^4(m+2)(m+4)(m+6)}{m^3(n-2)(n-4)(n-6)(n-8)}, \tag{6}$$

so the CENTRAL MOMENTS are given by

$$\mu_2 = \frac{2n^2(m+n-2)}{m(n-2)^2(n-4)} \tag{7}$$

$$\mu_3 = \frac{8n^3(m+n-2)(2m+n-2)}{m^2(n-2)^3(n-4)(n-6)} \tag{8}$$

$$\mu_4 = \frac{12n^4(m+n-2)\left[4(n-2)^2+m^2(n+10)+m(n-2)(n+10)\right]}{m^3(n-2)^4(n-4)(n-6)(n-8)}. \tag{9}$$

and the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \mu_1' = \frac{n}{n-2} \tag{10}$$

$$\sigma^2 = \frac{2n^2(m+n-2)}{m(n-2)^2(n-4)} \tag{11}$$

$$\gamma_1 = \frac{\mu_3}{\sigma^3} = 2\sqrt{\frac{2(n-4)}{m(m+n-2)}}\,\frac{2m+n-2}{n-6} \tag{12}$$

$$\gamma_2 = \frac{\mu_4}{\sigma^4} - 3 = \frac{3(n-4)\left[4(n-2)^2+m^2(n+10)+m(n-2)(n+10)\right]}{m(m+n-2)(n-6)(n-8)}. \tag{13}$$

The CHARACTERISTIC FUNCTION can be computed, but it is rather messy and involves the GENERALIZED HYPERGEOMETRIC FUNCTION ${}_3F_2(a,\ b,\ c;\ d,\ e;\ z)$. Letting

$$w \equiv \frac{\frac{mF}{n}}{1+\frac{mF}{n}} \tag{14}$$

gives a BETA DISTRIBUTION (Beyer 1987, p. 536).

Snub Cube

The 38-faced ARCHIMEDEAN SOLID A_7, also called the SNUB CUBOCTAHEDRON, whose faces are $32\{3\}+6\{4\}$. It has two ENANTIOMERS. It is UNIFORM POLYHEDRON U_{12} and Wenninger model W_{17}. It has SCHLÄFLI SYMBOL $s\{{3 \atop 4}\}$ and WYTHOFF SYMBOL $|234$.

Its DUAL POLYHEDRON is the PENTAGONAL ICOSITETRAHEDRON. The INRADIUS r of the dual, MIDRADIUS ρ of the dual and solid, and CIRCUMRADIUS R for unit edge length are given by the unique positive real roots of the equations

$$896r^6-1248r^4+64r^2-1=0 \tag{1}$$

$$64\rho^6-112\rho^4+20\rho^2-1=0 \tag{2}$$

$$32R^6-80R^4+44R^2-7=0 \tag{3}$$

which given by

$$r=1.157661791\ldots \tag{4}$$

$$\rho=1.247223168\ldots \tag{5}$$

$$R=1.3437133737446\ldots \tag{6}$$

The SURFACE AREA of the snub cube of side length 1 is

$$S=6+8\sqrt{3} \tag{7}$$

and the VOLUME V is given by the positive real solution to the equation

$$729V^6-45684V^4+19386V^2-12842=0, \tag{8}$$

which is given approximately by

$$V\approx 7.88948. \tag{9}$$

The distances from the center to the centroids of the triangular and square faces are given by the unique positive roots to the equations

$$864r_3^6-1296r_3^4+36r_3^2-1=0 \tag{10}$$

$$32r_4^6-32r_4^4-12r_4^2-1=0, \tag{11}$$

which are given by

$$r_3=1.213355800\ldots \tag{12}$$

$$r_4=1.142613508\ldots \tag{13}$$

Snub Cube-Pentagonal Icositetrahedron Compound

The compound of the SNUB CUBE and its dual, the PENTAGONAL ICOSITETRAHEDRON. It can be constructed from the snub cube with unit edge length by heights h_3 and h_4, given by the unique positive real roots of

$$3456h_3^6-864h_3^4+216h_3^2-1=0 \tag{1}$$

$$128h_4^6+96h_4^4+16h_4^2-1=0. \tag{2}$$

The corresponding solid has edge lengths

$$128s_1^6-64s_1^4+16s_1^2-1=0 \tag{3}$$

$$s_2=1/2 \tag{4}$$

$$128s_3^6-6s_3^3-1=0, \tag{5}$$

and

$$s_4=\tfrac{1}{2}\sqrt{2}, \tag{6}$$

where s_1 and s_3 are unique real roots of the above

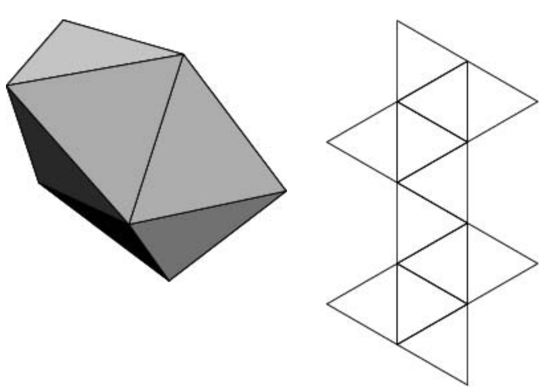
polynomials. The CIRCUMRADIUS is given by the root of

$$32R^6 - 80R^4 + 44R^2 - 7 = 0, \quad (7)$$

the SURFACE AREA by the root of

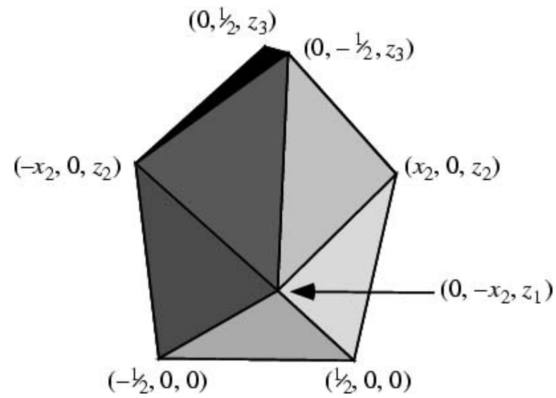
$$\begin{aligned} &1028869776 + 35418062592S - 45028405440S^2 \\ &+22712607360S^3 - 5396081328S^4 \\ &+463818960S^5 + 35732664S^6 - 7379424S^7 \\ &+23652S^8 + 29160S^9 - 576S^{10} - 36S^{11} + S^{12}, \end{aligned} \quad (8)$$

and VOLUME by the root of



$$128V^6 - 8864V^4 + 19152V^2 - 10609 = 0. \quad (9)$$

See also COMPOUND POLYHEDRON, PENTAGONAL ICOSITETRAHEDRON, SNUB CUBE



Snub Cuboctahedron

SNUB CUBE

Snub Disphenoid

The 12-faced convex DELTAHEDRA also known as the SIAMESE DODECAHEDRON, which is also JOHNSON SOLID J_{84}.

The coordinates of the VERTICES of a snub disphenoid of unit side length may be found by solving the set of four simultaneous equations

$$\left(\tfrac{1}{2}\right)^2 + x_2^2 + z_1^2 = 1$$

$$\left(x_2 - \tfrac{1}{2}\right)^2 + (z_3 - z_1)^2 = 1$$

$$\left(\tfrac{1}{2}\right)^2 + x_2^2 + (z_3 - z_2)^2 = 1$$

$$x_2^2 + x_2^2 + (z_2 - z_1)^2 = 1$$

for the four unknowns x_2, z_1, z_2, and z_3. The analytic solution requires solving the CUBIC EQUATION, and the solutions are given by the unique positive real roots of

$$2x_2^3 - 3x_2^2 - 2x_2 + 2 = 0 \quad (1)$$

$$32z_1^6 + 64z_1^4 - 22z_1^2 - 1 = 0 \quad (2)$$

$$16z_2^6 + 8z_2^4 - 15z_2^2 - 8 = 0 \quad (3)$$

$$2z_3^6 - z_3^4 - 8z_3^2 - 4 = 0. \quad (4)$$

Numerically,

$$x_2 \approx 0.644584$$

$$z_1 \approx 0.578369$$

$$z_2 \approx 0.989492$$

$$z_3 \approx 1.56786.$$

The SURFACE AREA of the unit snub disphenoid is

$$S = 3\sqrt{3}, \quad (5)$$

and the VOLUME V is given by the positive real root of

$$5832V^6 - 1377V^4 - 2160V^2 - 4 = 0, \quad (6)$$

approximately $V \approx 0.859494$.

TRUNCATED ICOSAHEDRON

Sociable Numbers

Numbers which result in a periodic ALIQUOT SEQUENCE, where an ALIQUOT SEQUENCE is the sequence of numbers obtained by repeatedly applying the restricted divisor function

$$s(n) = \sigma(n) - n \quad (1)$$

to n. Here $\sigma(n)$ is the usual DIVISOR FUNCTION.

If the period is 1, the number is called a PERFECT NUMBER. If the period is 2, the two numbers are called an AMICABLE PAIR. In general, if the period is $t \geq 3$, the number is called sociable of order t. Only two sociable numbers were known prior to 1970, the sets of orders 5 and 28 discovered by Poulet (1918). In 1970, Cohen discovered nine groups of order 4.

For example, 1264460 is a sociable number of order four since its ALIQUOT SEQUENCE is 1264460, 1547860, 1727636, 1305184, 1264460, ... The first few sociable numbers are 12496, 14316, 1264460, 2115324, 2784580, 4938136, ... (Sloane's A003416), which have orders 5, 28, 4, 4, 4, 4, ... (Sloane's A052470). The table below summarizes the numbers of sociable cycles known as a function of order as given in the compilation by Moews (1995).

order	known
3	0
4	53
5	1
6	2
8	2
9	1
28	1
total	60

Y. Kohmoto has considered a generalization of the sociable numbers defined according to the generalized ALIQUOT SEQUENCE

$$a(n) = \frac{\sigma(a(n-1))}{m}. \quad (2)$$

MULTIPERFECT NUMBERS are fixed points of this mapping, since if $a(n) = a(n-1)$, then

$$ma(n) = \sigma(a(n)), \quad (3)$$

which is the definition of an m-multiperfect number. If the sequence $a(n)$ becomes cyclic after $k > 1$ terms, it is then called an $1/m$-sociable number of order k.

If M_m and M_n are distinct MERSENNE PRIMES, then

$$\tfrac{1}{2}\sigma(2^{m-1}M_n) = \tfrac{1}{2}(2^m - 1)2^n = 2^{n-1}M_m \quad (4)$$

$$\tfrac{1}{2}\sigma(2(n-1)M_m) = 2^{m-1}M_n, \quad (5)$$

so $2^{m-1}M_n$ and $2^{n-1}M_m$ are $1/2$-sociable numbers of order 2.

The following table summarizes the smallest members of the generalized $1/m$-aliquot sequences of order k, found by Kohmoto.

m	k	starting numbers
3	2	14913024
4	2	2096640, 422688000
4	12	3396556800

Social Choice Theory

The theory of analyzing a decision between a collection of alternatives made by a collection of n voters with separate opinions. Any choice for the entire group should reflect the desires of the individual voters to the extent possible.

Fair choice procedures usually satisfy anonymity (invariance under permutation of voters), duality (each alternative receives equal weight for a single vote), and monotonicity (a change favorable for X does not hurt X). Simple majority vote is anonymous, dual, and monotone. May's theorem states a stronger result.

See also Anonymous, Arrow's Paradox, Dual Voting, May's Theorem, Monotonic Voting, Voting

Socle

The socle of a group G is the subgroup generated by its minimal normal subgroups. For example, the symmetric group S_4 has two nontrivial normal subgroups: A_4 and $N=\{\{1, 2, 3, 4\}, \{2, 1, 4, 3\}, \{3, 4, 1, 2\}, \{4, 3, 2, 1\}\}$. But A_4 contains N, so N is the only minimal subgroup, and the socle of S_4 is N.

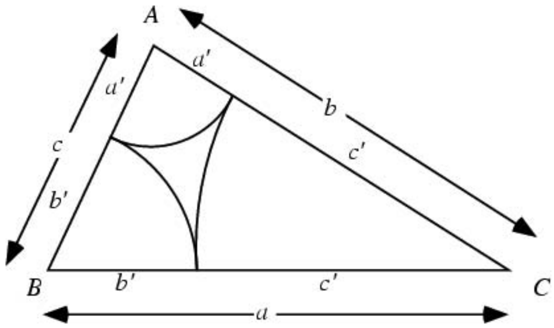
Soddy Centers

Soddy Points

Soddy Circles

Given three distinct noncollinear points A, B, and C, let three circles be drawn, one centered about each point and each one tangent to the other two. Call the



RADII r_i ($r_3 = a'$, $r_1 = b'$, $r_2 = c'$). Then the CIRCLES satisfy

$$a' + b' = c \quad (1)$$

$$a' + c' = b \quad (2)$$

$$b' + c' = a, \quad (3)$$

as shown in the diagram below.

Solving for the RADII then gives

$$a' = \tfrac{1}{2}(b + c - a) \quad (4)$$

$$b' = \tfrac{1}{2}(a + c - b) \quad (5)$$

$$c' = \tfrac{1}{2}(a + b - c). \quad (6)$$

The TRIANGLE illustrated above has sides a, b, and c, and SEMIPERIMETER

$$s \equiv \tfrac{1}{2}(a + b + c). \quad (7)$$

Plugging in,

$$2s = (a' + b') + (a' + c') + (b' + c') = 2(a' + b' + c'), \quad (8)$$

giving

$$a' + b' + c' = s. \quad (9)$$

In addition,

$$a = b' + c' = a' + b' + c' - a' = s - a'. \quad (10)$$

Switching a and a' to opposite sides of the equation and noting that the above argument applies equally well to b' and c' then gives

$$a' = s - a \quad (11)$$

$$b' = s - b \quad (12)$$

$$c' = s - c. \quad (13)$$

As can be seen from the first figure, there exist exactly two nonintersecting CIRCLES which are TANGENT to all three CIRCLES. These are called the inner and outer Soddy circles (S and S', respectively), and their centers are called the inner and outer SODDY POINTS.

The inner Soddy circle is the solution to the FOUR COINS PROBLEM and its center S, the inner Soddy point, is the EQUAL DETOUR POINT. The center of the outer Soddy circle, the outer Soddy point S', is the ISOPERIMETRIC POINT (Kimberling 1994).

Frederick Soddy (1936) gave the FORMULA for finding the RADII of the Soddy circles (r_4) given the RADII r_i ($i = 1, 2, 3$) of the other three. The relationship is

$$2\left(\epsilon_1^2 + \epsilon_2^2 + \epsilon_3^2 + \epsilon_4^2\right) = (\epsilon_1 + \epsilon_2 + \epsilon_3 + \epsilon_4)^2, \quad (14)$$

where $\epsilon_i \equiv \pm\kappa_i = \pm 1/r_i$ are the so-called BENDS, defined as the signed CURVATURES of the CIRCLES. If the contacts are all external, the signs are all taken as POSITIVE, whereas if one circle surrounds the other three, the sign of this circle is taken as NEGATIVE (Coxeter 1969). Using the QUADRATIC FORMULA to solve for ϵ_4, expressing in terms of radii instead of curvatures, and simplifying gives

$$r_4^{\pm} = \frac{r_1 r_2 r_3}{r_2 r_3 + r_1(r_2 + r_3) \pm 2\sqrt{r_1 r_2 r_3 (r_1 + r_2 + r_3)}}. \quad (15)$$

Here, the NEGATIVE solution corresponds to the outer Soddy circle and the POSITIVE one to the inner Soddy circle.

This FORMULA is called the DESCARTES CIRCLE THEOREM since it was known to Descartes. Soddy extended the result to TANGENT SPHERES, and Gosper has further extended the result to $n + 2$ mutually tangent n-D HYPERSPHERES.

Bellew has derived a generalization applicable to a CIRCLE surrounded by n CIRCLES which are, in turn, circumscribed by another CIRCLE. The relationship is

$$\left[n(c_n - 1)^2 + 1\right] \sum_{i=1}^{n+1} \kappa_i^2 + n\left(3nc_n^2 - 2n - 6\right)c_n^2(c_n - 1)^2 = \left[\frac{f(n)}{n(e_n - 1) + 1}\right], \quad (16)$$

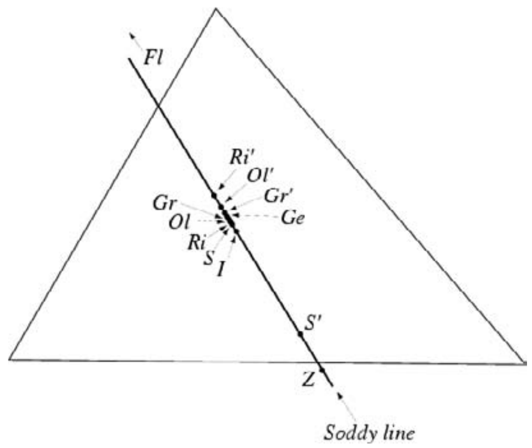
where κ_{n+1} is the curvature of the central circle,

$$f(n) = \left[n(c_n - 1)^2 + 1\right] \sum_{i=1}^{n+1} \kappa_i + nc_n(c_n - 1) \times \left[nc_n^2 + (3 - n)c_n - 4\right] \quad (17)$$

and

$$c_n \equiv \csc\left(\frac{\pi}{n}\right). \quad (18)$$

For $n = 3$, this simplifies to the DESCARTES CIRCLE THEOREM



$$2 \sum_{i=1}^{4} \kappa_1^2 = \left(\sum_{i=1}^{4} \kappa_i\right)^2. \quad (19)$$

Soddy Line

A line on which the incenter I, Gergonne point Ge, inner and outer Soddy points S and S', Griffiths points Gr, Gr', Oldknow points Ol, Ol', Rigby points Ri, Ri', and Fletcher point Fl lie. The Soddy line can be given parametrically in trilinear coordinates by

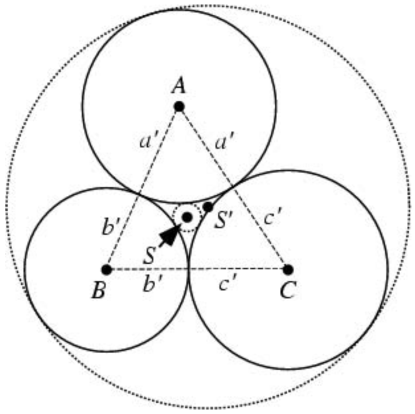
$$I + \lambda Ge,$$

where λ is a parameter (Oldknow 1996). The Soddy line is also given by

$$\sum (f-e)\alpha = 0,$$

where cyclic permutations of the d, e, and f are taken and the sum is over trilinear coordinates α, β, and γ. The following table gives the values of λ corresponding to a number of special points on the Soddy line.

λ	Center
-4	Outer Griffiths point Gr'
-2	Outer Oldknow point Ol'
$-\frac{4}{3}$	Outer Rigby point Ri'
-1	Outer Soddy point S'
0	incenter I
1	Inner Soddy point S
$\frac{4}{3}$	Inner Rigby point Ri
2	Inner Oldknow point Ol
4	Inner Griffiths point Gr
∞	Gergonne point Ge



S', I, S, and Ge form a harmonic range (Vandeghen 1964, Oldknow 1996). There are a total of 22 harmonic ranges for sets of four points out of these 10 (Oldknow 1996). The Soddy line intersects the Euler line in the de Longchamps point, and the Gergonne line in the Fletcher point.

Solenoidal Field

A solenoidal VECTOR FIELD satisfies

$$\nabla \cdot \mathbf{B} = 0 \tag{1}$$

for every VECTOR $\mathbf{B}$, where $\nabla \cdot \mathbf{B}$ is the DIVERGENCE. If this condition is satisfied, there exists a vector $\mathbf{A}$, known as the VECTOR POTENTIAL, such that

$$\mathbf{B} \equiv \nabla \times \mathbf{A}, \tag{2}$$

where $\nabla \times \mathbf{A}$ is the CURL. This follows from the vector identity

$$\nabla \cdot \mathbf{B} = \nabla \cdot (\nabla \times \mathbf{A}) = 0. \tag{3}$$

If $\mathbf{A}$ is an IRROTATIONAL FIELD, then

$$\mathbf{A} \times \mathbf{r} \tag{4}$$

is solenoidal. If $\mathbf{u}$ and $\mathbf{v}$ are irrotational, then

$$\mathbf{u} \times \mathbf{v} \tag{5}$$

is solenoidal. The quantity

$$(\nabla u) \times (\nabla v), \tag{6}$$

where ∇u is the GRADIENT, is always solenoidal. For a function ϕ satisfying LAPLACE'S EQUATION

$$\nabla^2 \phi = 0. \tag{7}$$

it follows that $\nabla\phi$ is solenoidal (and also IRROTATIONAL).

Solid of Revolution

To find the VOLUME of a solid of rotation by adding up a sequence of thin cylindrical shells, consider a region bounded above by $y = f(x)$, below by $y = g(x)$, on the left by the LINE $x = a$, and on the right by the LINE $x = b$. When the region is rotated about the Y-AXIS, the resulting VOLUME is given by

$$V = 2\pi \int_b^a x[f(x) - g(x)] \, dx.$$

To find the volume of a solid of rotation by adding up a sequence of thin flat disks, consider a region bounded above by $y = f(x)$, below by $y = g(x)$, on the left by the LINE $x = a$, and on the right by the LINE $x = b$. When the region is rotated about the X-AXIS, the resulting VOLUME is

$$V = \pi \int_b^a \left\{ [f(x)]^2 - [g(x)]^2 \right\} dx.$$

See also SURFACE OF REVOLUTION, VOLUME

Solid Partition

Solid partitions are generalizations of PLANE PARTITIONS. MacMahon (1960) conjectured the GENERATING FUNCTION for the number of solid partitions was

$$f(z)=\frac{1}{(1-z)(1-z^2)^3(1-z^3)^6(1-z^4)^{10}\cdots},$$

but this was subsequently shown to disagree at $n=6$ (Atkin *et al.* 1967). Knuth (1970) extended the tabulation of values, but was unable to find a correct generating function. The first few values are 1, 4, 10, 26, 59, 140, ... (Sloane's A000293).

See also PARTITION FUNCTION P

Solitary Number

A number which does not have any FRIENDS. Solitary numbers include all PRIMES, PRIME POWERS, and numbers for which $(n,\ \sigma(n))=1$, where $(a,\ b)$ is the GREATEST COMMON DIVISOR of a and b and $\sigma(n)$ is the DIVISOR FUNCTION. The first few numbers satisfying $(n,\ \sigma(n))=1$ are 1, 2, 3, 4, 5, 7, 8, 9, 11, 13, 16, 17, 19, 21, ... (Sloane's A014567).

However, there exist numbers such as $n=18$, 45, 48, and 52 which are solitary but for which $(n,\ \sigma(n))\neq 1$. It is believed that 10, 14, 15, 20, 22, and many others are also solitary, although a proof appears to be extremely difficult.

Solomon's Seal Polygon

HEXAGRAM

Soluble Group

SOLVABLE GROUP

Solvable Congruence

A CONGRUENCE that has a solution.

Solvable Group

A solvable group is a GROUP having a "normal series" such that each "normal factor" is ABELIAN. The special case of a solvable FINITE GROUP is a group whose composition indices are all PRIME NUMBERS. Solvable groups are sometimes called "soluble groups," a turn of phrase that is a source of possible amusement to chemists.

The term "solvable" derives from this type of group's relationship to GALOIS'S THEOREM, namely that the SYMMETRIC GROUP S_n is unsolvable for $n \geq 5$ while it is solvable for $n = 1$, 2, 3, and 4. As a result, the POLYNOMIAL equations of degree ≥ 5 are not solvable using finite additions, multiplications, divisions, and ROOT EXTRACTIONS.

Every FINITE GROUP of order < 60, every ABELIAN GROUP, and every SUBGROUP of a solvable group is solvable. Betten (1996) has computed a table of solvable groups of order up to 242 (Besche and Eick 1999).

See also ABELIAN GROUP, COMPOSITION SERIES, GALOIS'S THEOREM, SOLVABLE LIE GROUP, SYMMETRIC GROUP

Solvable Lie Algebra

A LIE ALGEBRA $\mathfrak{g}$ is solvable when its COMMUTATOR SERIES, or derived series, $\mathfrak{g}^k$ vanishes for some k. Any NILPOTENT LIE ALGEBRA is solvable. The basic example is the VECTOR SPACE of UPPER TRIANGULAR MATRICES, because every time two such matrices commute, their nonzero entries move further from the diagonal.

The following *Mathematica* function tests whether a Lie algebra $\mathfrak{g}$ is solvable, when given a list of matrices which form a basis for $\mathfrak{g}$.

```
MatrixBasis[a_-
List]:=Partition[#1,Length[a[[1]]]]&/@
   LatticeReduce[Flatten/@a]
              LieCommutator[a_,b_]:=a.b-b.a
NextDerived[{}]={};
                        NextDerived[g_List]:=
MatrixBasis[Flatten[Outer[LieCommutator,g,-
g,1],1]]              SolvableLieQ[g_List]:=
FixedPoint[NextDerived,g]=={}
```

For example,

```
borel5=Flatten[Table[ReplacePart[
                                         Ta-
ble[0,{i,5},{j,5}],1,{k,l}],{k,5},{l,k,5}],1];
  SolvableLieQ[borel5]
```

yields `True`.

See also BOREL SUBALGEBRA, COMMUTATOR SERIES (LIE ALGEBRA), LIE ALGEBRA, LIE GROUP, NILPOTENT

LIE GROUP, NILPOTENT LIE ALGEBRA, REPRESENTATION (LIE ALGEBRA), REPRESENTATION (SOLVABLE LIE GROUP), SOLVABLE LIE GROUP, SPLIT SOLVABLE LIE ALGEBRA

Solvable Lie Group

A solvable Lie group is a LIE GROUP G which is CONNECTED and whose LIE ALGEBRA $\mathfrak{g}$ is a SOLVABLE LIE ALGEBRA. That is, the COMMUTATOR SERIES

$$\mathfrak{g}^1 = [\mathfrak{g}, \mathfrak{g}], \ \mathfrak{g}^2 = [\mathfrak{g}^1 \cdot \mathfrak{g}^1], \ \ldots \tag{1}$$

eventually vanishes, $\mathfrak{g}^k = 0$ for some k. Since NILPOTENT LIE ALGEBRAS are also SOLVABLE, any NILPOTENT LIE GROUP is a solvable Lie group.

The basic example is the GROUP of invertible UPPER TRIANGULAR MATRICES with positive DETERMINANT, e.g.,

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ 0 & a_{22} & a_{23} \\ 0 & 0 & a_{33} \end{bmatrix} \tag{2}$$

such that $\prod_i a_{ii} > 0$. The LIE ALGEBRA $\mathfrak{g}$ of G is its TANGENT SPACE at the identity matrix, which is the VECTOR SPACE of all upper triangular matrices, and it is a SOLVABLE LIE ALGEBRA. Its COMMUTATOR SERIES is given by

$$\mathfrak{g}^1 = \begin{bmatrix} 0 & b_{12} & b_{13} \\ 0 & 0 & b_{23} \\ 0 & 0 & 0 \end{bmatrix} \tag{3}$$

$$\mathfrak{g}^2 = \begin{bmatrix} 0 & 0 & c_{13} \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \tag{4}$$

$$\mathfrak{g}^3 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}. \tag{5}$$

Any real solvable Lie group is DIFFEOMORPHIC to EUCLIDEAN SPACE. For instance, the group of matrices in the example above is diffeomorphic to $\mathbb{R}^6$, via the EXPONENTIAL MAPExponential Map (Lie Group). However, in general, the exponential map in a SOLVABLE LIE ALGEBRA need not be SURJECTIVE.

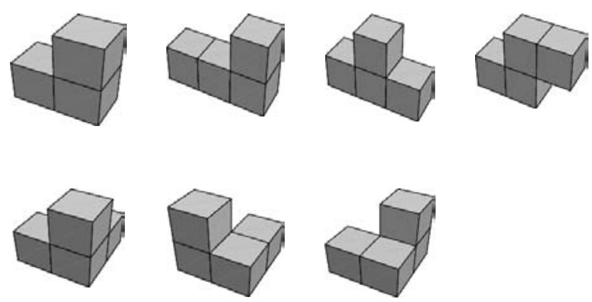
SOMA

Let $k \geq 0$ and $n \geq 2$ be integers. A SOMA, or more specifically a SOMA(k, n), is an $n \times n$ array A, whose entries are k-subsets of a kn-set Ω, such that each element of Ω occurs exactly once in each row and exactly once in each column of A, and no 2-subset of Ω is contained in more than one entry of A (Soicher 1999).



A SOMA(k, n) can be constructed by superposing k mutually orthogonal LATIN SQUARES of order n with pairwise disjoint symbol-sets, and so a SOMA(k, n) can be seen as a generalization of k mutually orthogonal LATIN SQUARES of order n.

Soma Cube

A solid DISSECTION puzzle invented by Piet Hein during a lecture on Quantum Mechanics by Werner Heisenberg. There are seven soma pieces composed of all the *irregular* face-joined cubes (POLYCUBES) with ≤ 4 cubes. The object is to assemble the pieces into a CUBE. There are 240 essentially distinct ways of doing so (Beeler 1972, Berlekamp *et al.* 1982), as first enumerated one rainy afternoon in 1961 by J. H. Conway and Mike Guy.

A commercial version of the cube colors the pieces black, green, orange, white, red, and blue. When the 48 symmetries of the cube, three ways of assembling the black piece, and 2^5 ways of assembling the green, orange, white, red, and blue pieces are counted, the total number of solutions rises to 1,105,920.

Somer-Lucas Pseudoprime

An ODD COMPOSITE NUMBER N is called a Somer-Lucas d-pseudoprime (with $d \geq 1$) if there EXISTS a nondegenerate LUCAS SEQUENCE $U(P, Q)$ with $U_0 = 0$, $U_1 = 1$, $D = P^2 - 4Q$, such that $(N, D) = 1$ and the rank appearance of N in the sequence $U(P, Q)$ is $(1/a)(N - (D/N))$, where (D/N) denotes the JACOBI SYMBOL.

Sommerfeld's Formula

There are (at least) two equations known as Sommerfeld's formula. The first is

$$J_\nu(z) = \frac{1}{2\pi} \int_{-\eta+i\infty}^{2\pi-\eta+i\infty} e^{iz \cos t} e^{i\nu(t-\pi/2)}\, dt,$$

where $J_\nu(z)$ is a BESSEL FUNCTION OF THE FIRST KIND. The second states that under appropriate restrictions,

$$\int_0^\infty J_0(\tau r) e^{-|x|\sqrt{\tau^2-k^2}} \frac{\tau\, d\tau}{\sqrt{\tau^2 - k^2}} = \frac{e^{ik\sqrt{\tau^2+k^2}}}{\sqrt{r^2 + x^2}}.$$

Somos Sequence

The Somos sequences are a set of related symmetrical RECURRENCE RELATIONS which, surprisingly, always give integers. The Somos sequence of order k is defined by

$$a_n = \frac{\sum_{j=1}^{\lfloor k/2 \rfloor} a_{n-j} a_{n-(k-j)}}{a_{n-k}},$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION and $a_j = 1$ for $j = 0$, ..., $k-1$. The 2- and 3-Somos sequences consist entirely of 1s. The k-Somos sequences for $k = 4$, 5, 6, and 7 are

$$a_n = \frac{a_{n-1}a_{n-3} + a_{n-2}^2}{a_{n-4}}$$

$$a_n = \frac{a_{n-1}a_{n-4} + a_{n-2}a_{n-3}}{a_{n-5}}$$

$$a_n = \frac{1}{a_{n-6}} \left[a_{n-1}a_{n-5} + a_{n-2}a_{n-4} + a_{n-3}^2 \right]$$

$$a_n = \frac{1}{a_{n-7}} \left[a_{n-1}a_{n-6} + a_{n-2}a_{n-5} + a_{n-3}a_{n-4} \right].$$

giving 1, 1, 1, 2, 3, 7, 23, 59, 314, 1529, ... (Sloane's A006720), 1, 1, 1, 1, 2, 3, 5, 11, 37, 83, 274, 1217, ... (Sloane's A006721), 1, 1, 1, 1, 1, 3, 5, 9, 23, 75, 421, 1103, ... (Sloane's A006722), 1, 1, 1, 1, 1, 1, 3, 5, 9, 17, 41, 137, 769, ... (Sloane's A006723). Gale (1991) gives simple proofs of the integer-only property of the 4-Somos and 5-Somos sequences. Hickerson proved 6-Somos generates only integers using computer algebra, and empirical evidence suggests 7-Somos is also integer-only.

However, the k-Somos sequences for $k \geq 8$ do not give integers. The values of n for which a_n first becomes nonintegral for the k-Somos sequence for $k = 8$, 9, ... are 17, 19, 20, 22, 24, 27, 28, 30, 33, 34, 36, 39, 41, 42, 44, 46, 48, 51, 52, 55, 56, 58, 60, ... (Sloane's A030127).

Sophie Germain Prime

A PRIME p is said to be a Sophie Germain prime if both p and $2p+1$ are PRIME. The first few Sophie Germain primes are 2, 3, 5, 11, 23, 29, 41, 53, 83, 89, 113, 131, ... (Sloane's A005384).

Sophie Germain primes p OF THE FORM $p=k\cdot 2^n-1$ (which makes $2p+1$ a PRIME) correspond to the indices of composite MERSENNE NUMBERS M_p. The largest known Sophie Germain prime is $92.305\times 2^{16.998}+1$, found in 1998 (Hoffman 1998, p. 190). It is not known if there are an infinite number of Sophie German primes (Hoffman 1998, p. 190).

Around 1825, Sophie Germain proved that the first case of FERMAT'S LAST THEOREM is true for such primes, i.e., if p is a Sophie Germain prime, there do not exist INTEGERS x, y, and z different from 0 and not multiples of p such that

$$x^p+y^p=z^p.$$

Sorites Paradox

Sorites paradoxes are a class of paradoxical arguments also known as little-by-little arguments. The name "sorites" derives from the Greek word *soros*, meaning "pile" or "heap." Sorites paradoxes are exemplified by the problem that a single grain of wheat does not comprise a heap, nor do two grains of wheat, three grains of wheat, etc. However, at some point, the collection of grains becomes large enough to be called a heap, but there is apparently no definite point where this occurs.

Sorting

Sorting is the rearrangement of numbers (or other orderable objects) in a list into their correct lexographic order. Alphabetization is therefore a form of sorting. Because of the extreme importance of sorting in almost all database applications, a great deal of effort has been expended in the creation and analysis of efficient sorting algorithms.

The minimum number of comparisons $a(n)$ needed for a merge sort of n elements for $n=1, 2, ...$ are 0, 1, 3, 5, 7, 10, 13, 16, 19, 22, 26, 30, ... (Sloane's A001768). An upper limit $b(n)$ is given by the sequence

$$a(n) \leq b(n) = 1 + kn - 2^k$$

where

$$k = \lfloor \log_2 n \rfloor + 1,$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION (Steinhaus 1983, pp. 55–6), or equivalently,

$$b(n) = \sum_{k=1}^{n} \lceil \log_2 k \rceil,$$

giving 0, 1, 3, 5, 8, 11, 14, 17, 21, 25, 29, ... (Sloane's A001855).

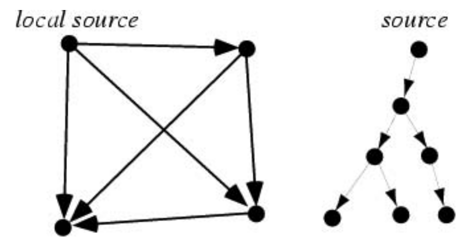
Sort-Then-Add Sequence



A sequence produced by sorting the digits of a number and adding them to the previous number. The algorithm terminates when a sorted number is obtained. For $n = 1, 2, ...$, the algorithm terminates on 1, 2, 3, 4, 5, 6, 7, 8, 9, 11, 11, 12, 13, 14, 15, 16, 17, 18, 19, 22, 33, ... (Sloane's A033862). The first few numbers not known to terminate are 316, 452, 697, 1376, 2743, 5090, ... (Sloane's A033861). The least numbers of sort-then-add persistence $n = 1, 2, ...$, are 1, 10, 65, 64, 175, 98, 240, 325, 302, 387, 198, 180, 550, ... (Sloane's A033863).

Space

The concept of a space is an extremely general and important mathematical construct. Members of the space obey certain addition properties. Spaces which have been investigated and found to be of interest are usually named after one or more of their investigators. This practice unfortunately leads to names which give very little insight into the relevant properties of a given space.

The everyday type of space familiar to most people is called EUCLIDEAN SPACE. In Einstein's theory of Special Relativity, Euclidean 3-space plus time (the "fourth dimension") are unified into the so-called MINKOWSKI SPACE. One of the most general type of mathematical spaces is the TOPOLOGICAL SPACE.

Space Conic

SKEW CONIC

Space Curve

A curve which may pass through any region of 3-D space, as contrasted to a PLANE CURVE which must lie in a single PLANE. Von Staudt (1847) classified space curves geometrically by considering the curve

$$\phi : I \to \mathbb{R}^3 \quad (1)$$

at $t_0 = 0$ and assuming that the parametric functions $\phi_i(t)$ for $i = 1, 2, 3$ are given by POWER SERIES which converge for small t. If the curve is contained in no PLANE for small t, then a coordinate transformation puts the PARAMETRIC EQUATIONS in the normal form

$$\phi_1(t) = t^{1+k_1} + \ldots \quad (2)$$

$$\phi_2(t) = t^{2+k_1+k_2} + \ldots \quad (3)$$

$$\phi_3(t) = t^{3+k_1+k_2+k_3} + \ldots \quad (4)$$

for integers $k_1, k_2, k_3 \geq 0$, called the local numerical invariants.

Space-Filling Polyhedron

A space-filling polyhedron is a POLYHEDRON which can be used to generate a TESSELLATION of space. Although even Aristotle himself proclaimed in his work *On the Heavens* that the TETRAHEDRON fills

space, it in fact does not (Hilbert and Cohn-Vossen 1999, p. 45). The CUBE is the only PLATONIC SOLID possessing this property (Gardner 1984, pp. 183–84). However, a combination of TETRAHEDRA and OCTAHEDRA do fill space (Steinhaus 1983, p. 210; Wells 1991, p. 232). In addition, octahedra, truncated octahedron, and cubes, combined in the ratio 1:1:3, can also fill space (Wells 1991, p. 235).

Of the Archimedean solids, the RHOMBIC DODECAHEDRON and TRUNCATED OCTAHEDRON are space-fillers (Steinhaus 1983, pp. 185–90; Wells 1991, pp. 233–34). The ELONGATED DODECAHEDRON and hexagonal PRISM are also space-fillers. These five solids are all "primary" PARALLELOHEDRA (Coxeter 1973). In 1914, Föppl discovered a space-filling compound of tetrahedra and truncated tetrahedra (Wells 1991, p. 234).

The CUBOCTAHEDRON, TRIANGULAR ORTHOBICUPOLA, and squashed dodecahedron appearing in SPHERE PACKING also fill space (Steinhaus 1983, pp. 203–07), as does an arbitrary TRIANGULAR PRISM or any non-self-intersecting quadrilateral PRISM.

There exists a tetrahedron with bevelled edges which fills space (Wells 1991, p. 234). There exists one 16-sided space-filling POLYHEDRON, but it is unknown if it is the unique 16-sided space-filler. There exists an 18-faced space-filler, as well space-fillers of up to 38 faces, as discovered by P. Engel in 1980 (Wells 1991, pp. 234–35). P. Schmitt discovered a nonconvex aperiodic polyhedral space-filler around 1990, and a convex POLYHEDRON known as the SCHMITT-CONWAY BIPRISM which fills space only aperiodically was found by J. H. Conway in 1993 (Eppstein).

Span (Geometry)

The largest possible distance between two points drawn from a finite set of points.

See also COMPUTATIONAL GEOMETRY, CONVEX HULL, JUNG'S THEOREM, POINT DISTANCES

Span (Link)

The span of an unoriented LINK diagram (also called the SPREAD) is the difference between the highest and lowest degrees of its BRACKET POLYNOMIAL. The span is a topological invariant of a knot. If a KNOT K has a reduced alternating projection of n crossings, then the span of K is $4n$.

See also LINK

Span (Polynomial)

The difference between the highest and lowest degrees of a POLYNOMIAL.

Span (Set)

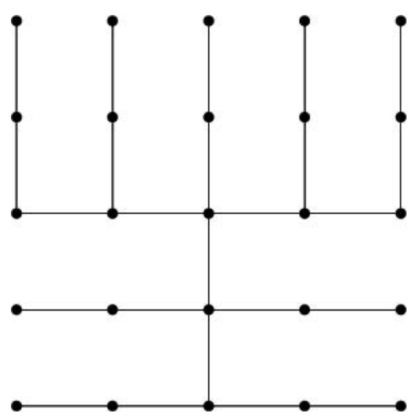
For a SET S, the span is defined by $\max S - \min S$, where max is the MAXIMUM and min is the MINIMUM.

References

Guy, R. K. *Unsolved Problems in Number Theory, 2nd ed.* New York: Springer-Verlag, p. 207, 1994.

Span (Vector Space)

The span of SUBSPACE generated by VECTORS $\mathbf{v}_1$ and $\mathbf{v}_2 \in \mathbb{V}$ is



$$\mathrm{Span}(\mathbf{v}_1,\ \mathbf{v}_2) \equiv \{r\mathbf{v}_1 + s\mathbf{v}_2 : r,\ s \in \mathbb{R}\}$$

A set of vectors $m = \{\mathbf{v}_1,\ \ldots,\ \mathbf{v}_n\}$ can be tested to see if they span n-D space using the following *Mathematica* function.

```
SpanningVectorsQ[m_List?MatrixQ]            : =
(NullSpace[m]  = =  {})
```

See also BASIS (VECTOR SPACE), LINEAR COMBINATION, NULLSPACE, VECTOR SPACE

Spanning Tree

A spanning tree of a GRAPH is a subset of $n-1$ edges which form a TREE. The shortest-path spanning tree is the tree have the smallest possible total distance, where the distance used is MANHATTAN DISTANCE (Skiena 1990, p. 227).

The number of nonidentical spanning trees of a GRAPH G is equal to any COFACTOR of the DEGREE MATRIX of G minus the ADJACENCY MATRIX of G (Skiena 1990, p. 235). This result is known as the MATRIX TREE THEOREM. A TREE contains a unique spanning tree, a CYCLE GRAPH C_n containing n spanning trees, and a COMPLETE GRAPH K_n contains n^{n-2} spanning trees (Skiena 1990, p. 236). A count of the spanning trees of a graph can be found using the command `NumberOfSpanningTrees[g]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

Spearman Rank Correlation Coefficient

A nonparametric (distribution-free) rank statistic proposed by Spearman in 1904 as a measure of the strength of the associations between two variables (Lehmann and D'Abrera 1998). The Spearman rank correlation coefficient can be used to give an R-ESTIMATE.

The Spearman rank correlation coefficient is defined by

$$r' \equiv 1 - 6 \sum \frac{d^2}{N(N^2-1)}, \tag{1}$$

where d is the difference in RANK of corresponding variables, and is an approximation to the exact CORRELATION COEFFICIENT

$$r \equiv \frac{\sum xy}{\sqrt{\sum x^2 \sum y^2}} \tag{2}$$

computed from the original data. Because it uses ranks, the Spearman rank correlation coefficient is much easier to compute.

The VARIANCE, KURTOSIS, and higher order MOMENTS are

$$\sigma^2 = \frac{1}{N-1} \tag{3}$$

$$\gamma_2 = -\frac{114}{25N} - \frac{6}{5N^2} - \ldots \quad (4)$$

$$\gamma_3 = \gamma_5 = \ldots = 0. \quad (5)$$

Student was the first to obtain the VARIANCE.

Special Linear Lie Algebra

Denoted $\mathfrak{sl}_n$.

See also LIE ALGEBRA, SPECIAL LIE ALGEBRA

Special Matrix

An INTEGER MATRIX whose entries satisfy

$$a_{ij} = \begin{cases} 0 & \text{if } j > i+1 \\ -1 & \text{if } j = i+1 \\ 0 \text{ or } 1 & \text{if } j \leq 1. \end{cases}$$

There are 2^{n-1} special MINIMAL MATRICES of size $n \times n$.

References

Knuth, D. E. "Problem 10470." *Amer. Math. Monthly* **102**, 655, 1995.

Special Orthogonal Group

The special orthogonal group $SO_n(q)$ is the SUBGROUP of the elements of GENERAL ORTHOGONAL GROUP $GO_n(q)$ with DETERMINANT 1. SO_3 (often written $SO(3)$ is the ROTATION GROUP for 3-dimensional space.

See also BIPOLYHEDRAL GROUP, GENERAL ORTHOGONAL GROUP, ICOSAHEDRAL GROUP, ROTATION GROUP, SPECIAL LINEAR GROUP, SPECIAL UNITARY GROUP

References

Conway, J. H.; Curtis, R. T.; Norton, S. P.; Parker, R. A.; and Wilson, R. A. Special Orthogonal Matrix

A SQUARE MATRIX A is a special orthogonal matrix if

$$\mathsf{A}\mathsf{A}^{\mathrm{T}} = \mathsf{I}, \tag{1}$$

where I is the IDENTITY MATRIX, and the DETERMINANT satisfies

$$\det \mathsf{A} = 1. \tag{2}$$

The first condition means that A is an ORTHOGONAL MATRIX, and the second restricts the determinant to +1 (while a *general* ORTHOGONAL MATRIX may have determinant -1 or $+1$). For example,

$$\frac{1}{\sqrt{2}}\begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix} \tag{3}$$

is a special orthogonal matrix since

$$\begin{bmatrix} \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} \\ \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{bmatrix}\begin{bmatrix} \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \tag{4}$$

and its DETERMINANT is $1/2-(-1/2)=1$. A matrix m can be tested to see if it is a special orthogonal matrix using the *Mathematica* function

```
SpecialOrthogonalQ[m_List?MatrixQ] : =
  (Transpose[m].m = = IdentityMatrix@Length@m
&& Det[m] = = 1)
```

The special orthogonal matrices are CLOSED under multiplication and the inverse operation, and therefore form a MATRIX GROUP called the SPECIAL ORTHOGONAL GROUP $SO(n)$.

See also INNER PRODUCT, ORTHOGONAL GROUP, ORTHOGONAL MATRIX, ORTHOGONAL TRANSFORMATION, SKEW SYMMETRIC MATRIX, SPECIAL LINEAR MATRIX, SPECIAL ORTHOGONAL GROUP, SPIN GROUP, UNITARY MATRIX

Special Point

A POINT which does not lie on at least one ORDINARY LINE.

See also ORDINARY POINT

References

Guy, R. K. "Unsolved Problems Come of Age." *Amer. Math. Monthly* **96**, 903–09, 1989.

Special Series Theorem

If the difference between the order and the dimension of a series is less than the GENUS (CURVE), then the series is special.

References

Coolidge, J. L. *A Treatise on Algebraic Plane Curves.* New York: Dover, p. 253, 1959.

Special Unitary Group

The special unitary group $SU_n(q)$ is the set of $n \times n$ UNITARY MATRICES with DETERMINANT +1 (having n^2-1 independent parameters). $SU(2)$ is HOMEOMORPHIC with the ORTHOGONAL GROUP $O_3^+(2)$. It is also called the UNITARY UNIMODULAR GROUP and is a LIE GROUP.

Special unitary groups can be represented by matrices

$$U(a,\ b) = \begin{bmatrix} a & b \\ -\bar{b} & \bar{a} \end{bmatrix}, \tag{1}$$

where $\bar{a}a+\bar{b}b=1$ and $a,\ b$ are the CAYLEY-KLEIN PARAMETERS. The special unitary group may also be represented by matrices

$$U(\xi,\ \eta,\ \zeta) = \begin{bmatrix} e^{i\xi}\cos\eta & e^{i\zeta}\sin\eta \\ -e^{-i\zeta}\sin\eta & e^{-i\xi}\cos\eta \end{bmatrix}, \tag{2}$$

or the matrices

$$U_x\left(\tfrac{1}{2}\phi\right) = \begin{bmatrix} \cos\left(\frac{1}{2}\phi\right) & i\sin\left(\frac{1}{2}\phi\right) \\ i\sin\left(\frac{1}{2}\phi\right) & \cos\left(\frac{1}{2}\phi\right) \end{bmatrix} \tag{3}$$

$$U_y\left(\tfrac{1}{2}\beta\right) = \begin{bmatrix} \cos\left(\frac{1}{2}\beta\right) & \sin\left(\frac{1}{2}\beta\right) \\ -\sin\left(\frac{1}{2}\beta\right) & \cos\left(\frac{1}{2}\beta\right) \end{bmatrix} \tag{4}$$

$$U_z(\xi) = \begin{bmatrix} e^{i\xi} & 0 \\ 0 & e^{-i\xi} \end{bmatrix} \tag{5}$$

The order $2j+1$ representation is

$$U_{p,\,q}^{(j)}(\alpha,\ \beta,\ \gamma)$$
$$=\sum_m \frac{(-1)^{m-q-p}\sqrt{(j+p)!(j-p)!(j+q)!(j-q)!}}{(j-p-m)!(j+q-m)!(m+p-q)!m!}$$
$$\times e^{iq\alpha}\cos^{2j+q-p-2m}\left(\tfrac{1}{2}\beta\right)\sin^{p+2m-q}\left(\tfrac{1}{2}\beta\right)e^{ip\gamma} \quad (6)$$

The summation is terminated by putting $1/(-N)! = 0$. The CHARACTER is given by

$$X^{(j)}(\alpha)=\begin{cases} 1+2\cos\alpha+\ldots+2\cos(j\alpha) \\ 2\left[\cos\left(\tfrac{1}{2}\alpha\right)+\cos\left(\tfrac{3}{2}\alpha\right)+\ldots+\cos(j\alpha)\right]\end{cases}$$
$$=\begin{cases} \dfrac{\sin\left[\left(j+\frac{1}{2}\right)\alpha\right]}{\sin\left(\frac{1}{2}\alpha\right)} & \text{for } j=0,\ 1,\ 2,\ \ldots \\ \dfrac{\sin\left[\left(j+\frac{1}{2}\right)\alpha\right]}{\sin\left(\frac{1}{2}\alpha\right)} & \text{for } j=\frac{1}{2},\ \frac{3}{2},\ \ldots. \end{cases} \quad (7)$$

References

Arfken, G. "Special Unitary Group, $SU(2)$ and $SU(2)$-O_3^+ Homomorphism." *Mathematical Methods for Physicists, 3rd ed.* Orlando, FL: Academic Press, pp. 253–59, 1985.

Conway, J. H.; Curtis, R. T.; Norton, S. P.; Parker, R. A.; and Wilson, R. A. "The Groups $GU_n(q)$, $SU_n(q)$, $PGU_n(q)$, and $PSU_n(q)=U_n(q)$." §2.2 in *Atlas of Finite Groups: Maximal Subgroups and Ordinary Characters for Simple Groups.* Oxford, England: Clarendon Press, p. x, 1985.

Special Unitary Matrix

A SQUARE MATRIX U is a special unitary matrix if

$$\mathsf{UU}^* = \mathsf{I}. \quad (1)$$

where I is the IDENTITY MATRIX and U* is the ADJOINT MATRIX, and the DETERMINANT is

$$\det \mathsf{U} = 1. \quad (2)$$

The first condition means that U is a UNITARY MATRIX, and the second condition provides a restriction beyond a general UNITARY MATRIX, which may have determinant $e^{i\theta}$ for θ any real number. For example,

$$\frac{1}{\sqrt{2}}\begin{bmatrix} i & i \\ i & -i \end{bmatrix} \quad (3)$$

is a special unitary matrix. A matrix m can be tested to see if it is a special unitary matrix using the *Mathematica* function

```
SpecialUnitaryQ[m_List?MatrixQ] : =
   (Conjugate@Transpose@m.m  = =  IdentityMa-
trix@Length@m
   && Det[m]  = =  1)
```

The special unitary matrices are CLOSED under multiplication and the inverse operation, and therefore form a MATRIX GROUP called the SPECIAL UNITARY GROUP $SU(n)$.

See also HERMITIAN INNER PRODUCT, SKEW HERMITIAN MATRIX, SPECIAL LINEAR MATRIX, SPECIAL UNITARY GROUP, SPIN GROUP, UNITARY GROUP UNITARY MATRIX

Species

A species of structures is a rule F which

1. Produces, for each finite set U, a finite set $F[U]$,
2. Produces, for each bijection $\sigma : U \to V$, a function

$$F[\sigma] : F[U] \to F[V].$$

The functions $F[\sigma]$ should further satisfy the following functorial properties:

1. For all bijections $\sigma : U \to V$ and $\tau : V \to W$,
$$F[\tau \circ \sigma] = F[\tau] \circ F[\sigma].$$
2. For the IDENTITY MAP $\mathrm{Id}_U : U \to U$,
$$F\,[\underset{U}{\mathrm{Id}}] = \underset{F[U]}{\mathrm{Id}}.$$

An element $\sigma \in F[U]$ is called an F-structure on U (or a structure of species F on U). The function $F[\sigma]$ is called the transport of F-structures along σ.

Spectral Rigidity

The mean square deviation of the best local fit straight line to a staircase cumulative spectral density over a normalized energy scale.

References

Ott, E. *Chaos in Dynamical Systems.* New York: Cambridge University Press, p. 341, 1993.

Spectral Theorem

Let H be a HILBERT SPACE, $B(H)$ the set of BOUNDED linear operators from H to itself, T an OPERATOR on H, and $\sigma(T)$ the SPECTRUM of T. Then if $T \in B(H)$ and T is normal, there exists a unique resolution of the identity E on the BOREL SUBSETS of $\sigma(T)$ which satisfies

$$T = \int_{\sigma(T)} \lambda\, dE(\lambda).$$

Furthermore, every projection $E(\omega)$ COMMUTES with every $S \in B(H)$ that COMMUTES with T.

References

Golub, G. H. and van Loan, C. F. *Matrix Computations, 3rd ed.* Baltimore, MD: Johns Hopkins University Press, p. 310, 1996.

Spectrum (Operator)

Let T be an OPERATOR on a HILBERT SPACE. The spectrum $\sigma(T)$ of T is the set of λ such that $(T - \lambda I)$ is not invertible on all of the HILBERT SPACE, where the λs are COMPLEX NUMBERS and I is the IDENTITY OPERATOR. The definition can also be stated in terms of the resolvent of an operator

$$\rho(T) = \{\lambda : (T - \lambda I) \text{ is invertible}\},$$

and then the spectrum is defined to be the complement of $\rho(T)$ in the COMPLEX PLANE. It is easy to demonstrate that $\rho(T)$ is an OPEN SET, which shows that the spectrum is closed (in fact, it is even compact).

If Ω is a domain in $\mathbb{R}^d$ (i.e., a Lebesgue measurable subset of $\mathbb{R}^d$ with finite nonzero LEBESGUE MEASURE), the Iosevich *et al.* (1999) say a set $\Lambda \subset \mathbb{R}^d$ is a spectrum of Ω is $\{e^{2\pi i x\lambda}\}_{\lambda\in\Lambda}$ is an ORTHOGONAL BASIS of $L^2(\Omega)$.

See also FUGLEDE'S CONJECTURE, HILBERT SPACE, ORTHOGONAL BASIS, SPECTRAL THEOREM

Spectrum (Ring)

The spectrum of a RING is the set of proper PRIME IDEALS,

$$\mathrm{Spec}(R) = \{\mathfrak{p} : \mathfrak{p} \text{ is a prime ideal in } \mathrm{R}\}. \quad (1)$$

The classical example is the spectrum of POLYNOMIAL RINGS. For instance,

$$\mathrm{Spec}(\mathbb{C}[x]) = \{\langle x - a\rangle : a \in \mathbb{C}\} \cup \{\langle 0\rangle\}. \quad (2)$$

and

$$\mathrm{Spec}(\mathbb{C}[x, y]) = \{\langle x - a, y - b\rangle, (a, b) \in \mathbb{C}^2\}$$
$$\cup \{\langle f(x, y)\rangle : f \text{ is irreducable}\} \cup \{\langle 0\rangle\}. \quad (3)$$

The points are, in classical algebraic geometry, ALGEBRAIC VARIETIES. Note that $\langle x - a, y - b\rangle$ are MAXIMAL IDEALS, hence also prime.

The spectrum of a ring has a TOPOLOGY called the ZARISKI TOPOLOGY. The closed sets are of the form

$$V(S) = \{\langle p\rangle : S \subset \langle p\rangle\}. \quad (4)$$

For example,

$$\mathrm{Spec}(\mathbb{Z}) = \{\langle p\rangle : p \text{ is prime}\} \cup \{\langle 0\rangle\}. \quad (5)$$

Every PRIME IDEAL is closed except for $\langle 0\rangle$, whose closure is $V(0) = \mathrm{Spec}(\mathbb{Z})$.

Spectrum Sequence

A spectrum sequence is a SEQUENCE formed by successive multiples of a REAL NUMBER a rounded down to the nearest INTEGER $s_n = \lfloor na \rfloor$. If a is IRRATIONAL, the spectrum is called a BEATTY SEQUENCE.

References

Kenney, J. F. and Keeping, E. S. *Mathematics of Statistics, Pt. 1, 3rd ed.* Princeton, NJ: Van Nostrand, p. 223, 1962.

Spencer's Formula

Define the notation

$$[n]f_0 = f_{-(n-1)/2} + \ldots + f_0 + \ldots + f_{(n-1)/2} \quad (1)$$

and let δ be the central difference, so

$$\delta^2 f_0 = f_1 - 2f_0 + f_{-1}. \quad (2)$$

Spencer's 21-term moving average formula is then given by

$$f'_0 = \frac{[5][5][7]}{5 \cdot 5 \cdot 7}(1 - 4\delta^2)f_0,$$

which, written explicitly, gives

$$f'_0 = \tfrac{1}{350}[60f_0 + 57(f_{-1} + f_1) + 47(f_{-2} + f_2) + 33(f_{-3} + f_3)$$
$$+18(f_{-4} + f_4) + 6(f_{-5} + f_5) - 2(f_{-6} + f_6) - 5(f_{-7} + f_7)$$
$$-5(f_{-8} + f_8) - 3(f_{-9} + f_9) - (f_{-10} + f_{10})] \quad (3)$$

Sphere

A sphere is defined as the set of all points in $\mathbb{R}^3$ which are a distance r (the "RADIUS") from a given point (the "CENTER"). Twice the RADIUS is called the DIAMETER, and pairs of points on opposite sides of a DIAMETER are called ANTIPODES. The term "sphere" technically refers to the outer surface of a "BUBBLE," which is denoted $\mathbb{S}^2$. However, in common usage, the word *sphere* is also used to mean the UNION of a sphere and its INTERIOR (a "solid sphere"), where the INTERIOR is called a BALL.

The SURFACE AREA of the sphere and VOLUME of the BALL of RADIUS R are given by

$$S = 4\pi R^2 \tag{1}$$

$$V = \tfrac{4}{3}\pi R^3 \tag{2}$$

(Beyer 1987, p. 130). In *On the Sphere and Cylinder* (ca. 225 BC), Archimedes became the first to derive these equations (although he expressed π in terms of the sphere's circular CROSS SECTION). The fact that

$$\frac{V_{\text{sphere}}}{V_{\text{circumscribed cylinder}} - V_{\text{sphere}}} = 2 \tag{3}$$

was also known to Archimedes (Steinhaus 1983, p. 223; Wells 1991, pp. 236–37).

Any CROSS SECTION through a sphere is a CIRCLE (or, in the degenerate case where the slicing PLANE is tangent to the sphere, a point). The size of the CIRCLE is maximized when the PLANE defining the CROSS SECTION passes through a DIAMETER.

The equation of a sphere of RADIUS r is given in CARTESIAN COORDINATES by

$$x^2 + y^2 + z^2 = r^2. \tag{4}$$

which is a special case of the ELLIPSOID

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1 \tag{5}$$

and SPHEROID

$$\frac{x^2 + y^2}{a^2} + \frac{z^2}{c^2} = 1. \tag{6}$$

A sphere may also be specified in SPHERICAL COORDINATES by

$$x = \rho \cos\theta \sin\phi \tag{7}$$

$$y = \rho \sin\theta \sin\phi \tag{8}$$

$$z = \rho \cos\phi. \tag{9}$$

where θ is an azimuthal coordinate running from 0 to 2π (LONGITUDE), ϕ is a polar coordinate running from 0 to π (COLATITUDE), and ρ is the RADIUS. Note that there are several other notations sometimes used in which the symbols for θ and ϕ are interchanged or where r is used instead of ρ. If ρ is allowed to run from 0 to a given RADIUS r, then a solid BALL is obtained.

The volume of the sphere, $V = 4/3\pi R^3$, can be found in Cartesian, cylindrical, and spherical coordinates, respectively, using the integrals

$$V = \int_{-R}^{R} \int_{-\sqrt{R^2-x^2}}^{\sqrt{R^2-x^2}} \int_{-\sqrt{R^2-x^2-y^2}}^{\sqrt{R^2-x^2-y^2}} dz\, dy\, dx \tag{10}$$

$$= \int_0^{2\pi} \int_0^{R} \int_{-\sqrt{R^2-x^2}}^{\sqrt{R^2-x^2}} r\, dz\, dr\, d\theta \tag{11}$$

$$= \int_0^{2\pi} \int_0^{\pi} \int_0^{R} \rho^2 \sin\phi\, d\rho\, d\phi\, d\theta. \tag{12}$$

Converting to "standard" parametric variables $a = \rho$, $u = \theta$, and $v = \phi$ gives the coefficients of the FIRST FUNDAMENTAL FORM

$$E = a^2 \sin^2 v \tag{13}$$

$$F = 0 \quad (14)$$

$$G = a^2. \quad (15)$$

SECOND FUNDAMENTAL FORM coefficients

$$e = a \sin^2 v \quad (16)$$

$$f = 0 \quad (17)$$

$$g = a. \quad (18)$$

AREA ELEMENT

$$dA = a \sin v \, du \wedge dv. \quad (19)$$

GAUSSIAN CURVATURE

$$K = \frac{1}{a^2}. \quad (20)$$

and MEAN CURVATURE

$$H = \frac{1}{a}. \quad (21)$$

A sphere may also be represented parametrically by letting $u \equiv r \cos \phi$, so

$$x = \sqrt{r^2 - u^2} \cos \theta \quad (22)$$

$$y = \sqrt{r^2 - u^2} \sin \theta \quad (23)$$

$$z = u, \quad (24)$$

where θ runs from 0 to 2π and u runs from $-r$ to r.

Given two points on a sphere, the shortest path on the surface of the sphere which connects them (the SPHERE GEODESIC) is an ARC of a CIRCLE known as a GREAT CIRCLE. The equation of the sphere with points $\{x_1, y_1, z_1\}$ and $\{x_2, y_2, z_2\}$ lying on a DIAMETER is given by

$$(x - x_1)(x - x_2) + (y - y_1)(y - y_2) + (z - z_1)(z - z_2) = 0. \quad (25)$$

Four points are sufficient to uniquely define a sphere. Given the points $\{x_i, y_i, z_i\}$ with $i = 1, 2, 3$, and 4, the sphere containing them is given by the beautiful DETERMINANT equation

$$\begin{vmatrix} x^2+y^2+z^2 & x & y & z & 1 \\ x_1^2+y_1^2+z_1^2 & x_1 & y_1 & z_1 & 1 \\ x_2^2+y_2^2+z_2^2 & x_2 & y_2 & z_2 & 1 \\ x_3^2+y_3^2+z_3^2 & x_3 & y_3 & z_3 & 1 \\ x_4^2+y_4^2+z_4^2 & x_4 & y_4 & z_4 & 1 \end{vmatrix} = 0 \quad (26)$$

(Beyer 1987, p. 210).

The generalization of a sphere in n dimensions is called a HYPERSPHERE. An n-D HYPERSPHERE can be specified by the equation

$$x_1^2 + x_2^2 + \ldots + x_n^2 = r^2. \quad (27)$$

The distribution of ANGLES for random rotation of a sphere is

$$P(\theta) = \frac{2}{\pi} \sin^2\left(\tfrac{1}{2}\theta\right), \quad (28)$$

giving a MEAN of $\pi/2 + 2/\pi$.

Sphere Embedding

A 4-sphere has POSITIVE CURVATURE, with

$$R^2 = x^2 + y^2 + z^2 + w^2 \quad (1)$$

$$2x \frac{dx}{dw} + 2y \frac{dy}{dw} + 2z \frac{dz}{dw} + 2w = 0. \quad (2)$$

Since

$$\mathbf{r} \equiv x\hat{\mathbf{x}} + y\hat{\mathbf{y}} + z\hat{\mathbf{z}}. \quad (3)$$

$$dw = -\frac{x\,dx + y\,dy + z\,dz}{w} = -\frac{\mathbf{r} \cdot d\mathbf{r}}{\sqrt{R^2 - r^2}}. \quad (4)$$

To stay on the surface of the sphere,

$$\begin{aligned} ds^2 &= dx^2 + dy^2 + dz^2 + dw^2 \\ &= dx^2 + dy^2 + dz^2 + \frac{r^2\,dr^2}{R^2 - r^2} \\ &= dr^2 + r^2\,d\Omega^2 + \frac{dr^2}{\frac{R^2}{r^2} - 1} \\ &= dr^2\left(1 + \frac{1}{\frac{R^2}{r^2} - 1}\right) + r^2\,d\Omega^2 \\ &= dr^2\left(\frac{\frac{R^2}{r^2}}{\frac{R^2}{r^2} - 1}\right) + r^2\,d\Omega^2 \\ &= \frac{dr^2}{1 - \frac{r^2}{R^2}} + r^2\,d\Omega^2. \end{aligned} \tag{5}$$

With the addition of the so-called expansion parameter, this is the Robertson-Walker line element.

Sphere Eversion

Smale (1958) proved that it is mathematically possible to turn a SPHERE inside-out without introducing a sharp crease at any point. This means there is a regular homotopy from the standard embedding of the 2-SPHERE in EUCLIDEAN 3-space to the mirror-reflection embedding such that at every stage in the homotopy, the sphere is being IMMERSED in EUCLIDEAN SPACE. This result is so counterintuitive and the proof so technical that the result remained controversial for a number of years.

In 1961, Arnold Shapiro devised an explicit eversion but did not publicize it. Phillips (1966) heard of the result and, in trying to reproduce it, actually devised an independent method of his own. Yet another eversion was devised by Morin, which became the basis for the movie by Max (1977). Morin's eversion also produced explicit algebraic equations describing the process. The original method of Shapiro was subsequently published by Francis and Morin (1979).

Sphere Geodesic

GREAT CIRCLE

Sphere Inversion

INVERSION in 3 dimensions with respect to an INVERSION SPHERE.

See also INVERSION, INVERSION SPHERE

Sphere Line Picking

Pick two points at random on a unit sphere. The first one can be placed at the north pole, i.e., assigned the coordinate (0, 0, 1), without loss of generality. The second point is then chosen at random using SPHERE POINT PICKING, and so can be assigned coordinates

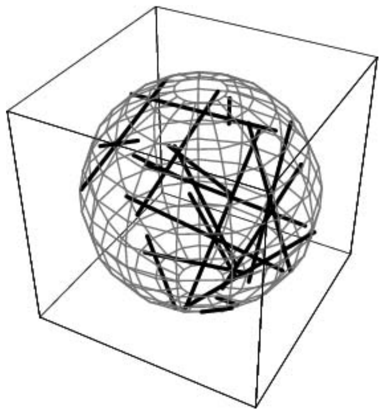
$$x = \sqrt{1 - u^2}\cos\theta \tag{1}$$

$$y = \sqrt{1 - u^2}\sin\theta \tag{2}$$

$$z = u \tag{3}$$

with $u \in [-1, 1]$ and $\theta \in [0, 2\pi)$. The distance ℓ between first and second points is then

$$\ell = \sqrt{x^2 + y^2 + (z - 1)^2} = \sqrt{2 - 2u}, \tag{4}$$



and solving for u gives

$$u = \tfrac{1}{2}(2 - \ell^2). \tag{5}$$

Now the probability function $P\ell$ for distance is then given by

$$P_\ell = P_u\left|\frac{\partial u}{\partial \ell}\right| = \tfrac{1}{2}\,\ell\,d\ell \tag{6}$$

(Solomon 1978, p. 163), since $P_u = 1/2$ and $du/d\ell = -\ell$. Here, $\ell \in [0, 2]$.

Therefore, somewhat surprisingly, large distances are the most common, contrary to most people's intuition. A plot of 15 random lines is shown above. The RAW MOMENTS are

$$\mu_n' = \langle \ell^n \rangle = \int_0^2 \ell^n P_\ell \, d\ell = \frac{2^{n+1}}{2+n}. \quad (7)$$

giving the first few as

$$\mu_1' = \tfrac{4}{3} \quad (8)$$

$$\mu_2' = 2 \quad (9)$$

$$\mu_3' = \tfrac{16}{5} \quad (10)$$

$$\mu_4' = \tfrac{16}{3}. \quad (11)$$

so the CENTRAL MOMENTS are

$$\mu = \tfrac{4}{3} \quad (12)$$

$$\mu_2 = \sigma^2 = \tfrac{2}{9} \quad (13)$$

$$\mu_3 = -\tfrac{8}{135} \quad (14)$$

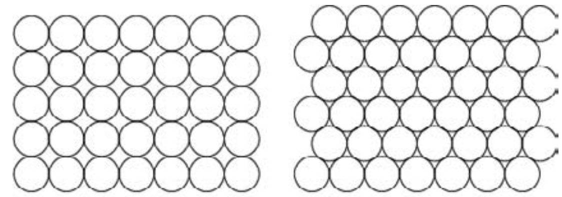
$$\mu_4 = \tfrac{16}{135}. \quad (15)$$

so the VARIANCE, SKEWNESS and KURTOSIS are

$$\sigma^2 = \tfrac{2}{9} \quad (16)$$

$$\gamma_1 = \tfrac{4}{5}\sqrt{2} \quad (17)$$

$$\gamma_2 = -\tfrac{5}{3} \quad (18)$$



(Solomon 1978, p. 163).

Sphere Packing

square packing *hexagonal packing*

In 2-D, there are two periodic CIRCLE PACKINGS for identical circles: square lattice and hexagonal lattice. Fejes Tóth (1940) proved that the hexagonal lattice is the densest of *all* possible plane packings (Conway and Sloane 1993, pp. 8–).

In 3-D, there are three periodic packings for identical spheres: cubic lattice, face-centered cubic lattice, and hexagonal lattice. It was hypothesized by Kepler in 1611 that close packing (cubic or hexagonal) is the densest possible (has the greatest PACKING DENSITY η, which is the fraction of a VOLUME filled by identical packed SPHERES), and this assertion is known as the KEPLER CONJECTURE. The problem of finding the densest packing of spheres (not necessarily periodic) is therefore known as the KEPLER PROBLEM. The KEPLER CONJECTURE is intuitively obvious, but the proof remained elusive until it was accomplished in a series of papers by Hales culminating in 1998. Gauss (1831) did prove that the face-centered cubic is the densest *lattice* packing in 3-D (Conway and Sloane 1993, p. 9). This result has since been extended to HYPERSPHERE PACKING.

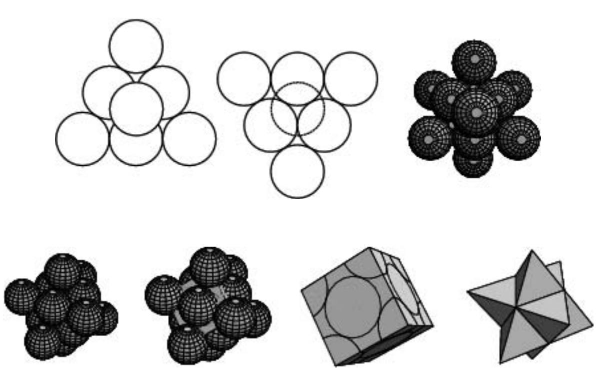
The maximum number of equivalent spheres (or n-D hyperspheres) which can touch an equivalent sphere (hypersphere) without intersections is called the n-D KISSING NUMBER.

In 3-D, face-centered cubic close packing and hexagonal close packing (which is distinct from hexagonal lattice packing), both give

$$\eta_{\rm CCP} = \eta_{\rm HCP} = \frac{\pi}{3\sqrt{2}} \approx 74.048\% \quad (1)$$

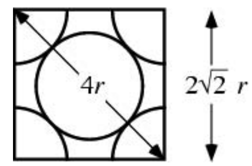
(Steinhaus 1983, p. 202; Wells 1986, p. 29; Wells 1991, p. 237). For packings in 3-D, C. A. Rogers (1958) showed that the maximum possible PACKING DENSITY $\eta_{\rm max}$ satisfies

$$\eta_{\rm max} < \sqrt{18}\left(\cos^{-1}\tfrac{1}{3} - \tfrac{1}{3}\pi\right) \approx 77.96355700\% \quad (2)$$



(Le Lionnais 1983). This was subsequently improved to 77.844% (Lindsey 1986), then 77.836% (Muder 1988). However, Rogers (1958) remarks that "many mathematicians believe, and all physicists know" that the actual answer is 74.048% (Conway and Sloane 1993, p. 3).

Hilbert and Cohn-Vossen (1999, pp. 48–0) consider a tetrahedral packing in which each sphere touched four neighbors and the density is $\pi\sqrt{3}/16 \approx 0.3401$.



The rigid packing with *lowest* density known has $\eta \approx 0.0555$ (Gardner 1966), significantly lower than that reported by Hilbert and Cohn-Vossen (1999, p. 51). To be rigid, each SPHERE must touch at least four others, and the four contact points cannot be in a single HEMISPHERE or all on one equator.

RANDOM CLOSE PACKING of spheres in 3-D gives packing densities in the range 0.06 to 0.65 (Jaeger and Nagel 1992, Torquato *et al.* 2000). The PACKING DENSITIES for several packing types are summarized in the following table.

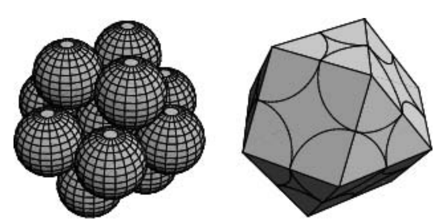
Packing	η (exact)	η	reference
loose packing	–	0.0555	Gardner (1966)
tetrahedral lattice	$\frac{\pi\sqrt{3}}{16}$	0.3401	Hilbert and Cohn-Vossen (1999, pp. 48–0)
cubic lattice	$\frac{\pi}{6}$	0.5236	
hexagonal lattice	$\frac{\pi}{3\sqrt{3}}$	0.6046	
random	–	0.6400	Jaeger and Nagel 1992
face-centered cubic lattice	$\frac{\pi}{3\sqrt{2}}$	0.7405	Steinhaus 1983, p. 202; Wells 1986, p. 29; Wells 1991, p. 237
square lattice (2-D)	$\frac{\pi}{4}$	0.7854	
hexagonal lattice (2-D)	$\frac{\pi}{2\sqrt{3}}$	0.9069	

Arranging layers of close-packed spheres such that the spheres of every third layer overlying one another gives cubic close packing. To see where the name comes from, consider packing six SPHERES together in the shape of an EQUILATERAL TRIANGLE and place another SPHERE on top to create a TRIANGULAR PYRAMID. Now create another such grouping of seven SPHERES and place the two PYRAMIDS together facing in opposite directions. A CUBE emerges (Steinhaus 1983, pp. 203–04). Connecting the centers of these 14 spheres gives a STELLA OCTANGULA.

Consider the CUBE defined by 14 spheres in cubic close packing, as illustrated above. This "unit cell" contains eight 1/8-spheres (one at each VERTEX) and six HEMISPHERES. The total VOLUME of SPHERES in the unit cell is therefore

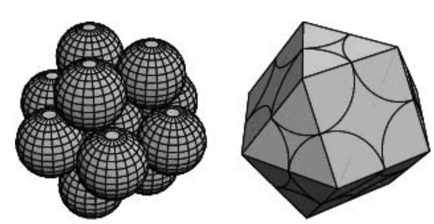
$$V_{\text{spheres in unit cell}} = \left(8 \cdot \tfrac{1}{8} + 6 \cdot \tfrac{1}{2}\right) \frac{4\pi}{3}\, r^3$$

$$= 4 \cdot \frac{4\pi}{3}\, r^3 = \tfrac{16}{3}\,\pi r^3. \tag{3}$$



The diagonal of the face is $4r$, so each side is $2\sqrt{2}r$. The VOLUME of the unit cell is therefore

$$V_{\text{unit cell}} = \left(2\sqrt{2}r\right)^3 = 16\sqrt{2}r^3. \tag{4}$$



and the PACKING DENSITY is

$$\eta_{\text{CCP}} = \frac{\frac{16}{3}\,\pi r^2}{16\sqrt{2}r^3} = \frac{\pi}{3\sqrt{2}} \tag{5}$$

(Conway and Sloane 1993, p. 2).

In cubic close packing, each sphere is surrounded by 12 other spheres. Taking a collection of 13 such spheres gives the cluster illustrated above. Connecting the centers of the external 12 spheres gives a CUBOCTAHEDRON (Steinhaus 1983, pp. 203–05; Wells 1991, p. 237).

In hexagonal close packing, layers of spheres are packed so that spheres in alternating layers overlie one another. As in cubic close packing, each sphere is surrounded by 12 other spheres. Taking a collection of 13 such spheres gives the cluster illustrated above. Connecting the centers of the external 12 spheres gives JOHNSON SOLID J_{27} known as the TRIANGULAR ORTHOBICUPOLA (Steinhaus 1983, pp. 203–05; Wells 1991, p. 237).

Hexagonal close packing must give the same packing density as cubic close packing, since sliding one sheet of SPHERES cannot affect the volume they occupy. To verify this, construct a 3-D diagram containing a hexagonal unit cell with three layers (Steinhaus 1983, pp. 203–04). Both the top and the bottom contain six 1/6-SPHERES and one HEMISPHERE. The total number of spheres in these two rows is therefore

$$2\left(6\cdot\tfrac{1}{6}+1\cdot\tfrac{1}{2}\right)=3. \qquad (6)$$

The VOLUME of SPHERES in the middle row cannot be simply computed using geometry. However, symmetry requires that the piece of the SPHERE which is cut off is exactly balanced by an extra piece on the other side. There are therefore three SPHERES in the middle layer, for a total of six, and a total VOLUME

$$V_{\text{spheres in unit cell}}=6\cdot\frac{4\pi}{3}r^3(3+3)=8\pi r^3. \qquad (7)$$

The base of the HEXAGON is made up of 6 EQUILATERAL TRIANGLES with side lengths $2r$. The unit cell base AREA is therefore

$$A_{\text{unit cell}}=6\left[\tfrac{1}{2}(2r)\left(\sqrt{3}r\right)\right]=6\sqrt{3}r^2. \qquad (8)$$

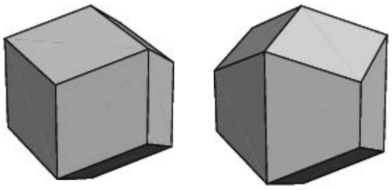
The height is the same as that of two TETRAHEDRA length $2r$ on a side, so

$$h_{\text{unit cell}}=2\left(2r\sqrt{\frac{2}{3}}\right). \qquad (9)$$

giving

$$\eta_{\text{HCP}}=\frac{8\pi r^3}{(6\sqrt{3}r^2)\left(4r\sqrt{\frac{2}{3}}\right)}=\frac{\pi}{3\sqrt{2}} \qquad (10)$$

(Conway and Sloane 1993, pp. 7 and 9).



If we had actually wanted to compute the VOLUME of SPHERE inside and outside the HEXAGONAL PRISM, we could use the SPHERICAL CAP equation to obtain

$$V_{\subset}=\tfrac{1}{3}\pi h^2(3r-h)=\frac{1}{3}\pi r^3\frac{1}{3}\left(3-\frac{1}{\sqrt{3}}\right)$$

$$=\frac{1}{9}\pi r^3\left(3-\frac{\sqrt{3}}{3}\right)=\tfrac{1}{27}\pi r^3\left(9-\sqrt{3}\right) \qquad (11)$$

$$V_{\supset}=\pi r^3\left[\tfrac{4}{3}-\tfrac{1}{27}(9-\sqrt{3})\right]=\tfrac{1}{27}\pi r^3\left(36-9+\sqrt{3}\right)$$

$$=\tfrac{1}{27}\pi r^3\left(27+\sqrt{3}\right). \qquad (12)$$

If spheres packed in a cubic lattice, face-centered cubic lattice, and hexagonal lattice are allowed to expand uniformly until running into each other, they form cubes, hexagonal prisms, and rhombic dodecahedra, respectively. In particular, if the spheres of cubic close packing are expanded until they fill up the gaps, they form a solid RHOMBIC DODECAHEDRON (left figure above), and if the spheres of hexagonal close packing are expanded, they form a second irregular dodecahedron consisting of six rhombi and six trapezoids (right figure above; Steinhaus 1983, p. 206). The latter can be obtained from the former by slicing in half and rotating the two halves 60° with respect to each other. The lengths of the short and long edges of the rotated dodecahedron have lengths 2/3 and 4/3 times the length of the rhombic faces. Both the RHOMBIC DODECAHEDRON and squashed dodecahedron are SPACE-FILLING POLYHEDRA.

Compressing a random packing gives polyhedra with an average of 13.3 faces (Coxeter 1958, 1961).

For sphere packing inside a CUBE, see Goldberg (1971), Schaer (1966), and Friedman.

Sphere Point Picking

To pick a random point on the surface of a UNIT SPHERE, it is incorrect to select SPHERICAL COORDINATES θ and ϕ from uniform distributions $\theta \in [0, 2\pi)$ and $\phi \in [0, \pi]$, since the area element $d\Omega = \sin\phi \, d\theta \, d\phi$ is a function of ϕ, and hence points picked in this way will be "bunched" near the poles (left figure above).

To obtain points such that any small area on the sphere is expected to contain the same number of points (right figure above), choose u and v to be random variates on $(0, 1)$. Then

$$\theta = 2\pi u \tag{1}$$

$$\phi = \cos^{-1}(2v - 1) \tag{2}$$

gives the SPHERICAL COORDINATES for a set of points which are uniformly distributed over $\mathbb{S}^2$. This works since the differential element of SOLID ANGLE is given by

$$d\Omega = \sin\phi \, d\theta \, d\phi = d\theta \, d(\cos\phi). \tag{3}$$

Similarly, we can pick $u = \cos\phi$ to be uniformly distributed (so we have $du = \sin\phi \, d\phi$) and obtain the points

$$x = \sqrt{1 - u^2} \cos\theta \tag{4}$$

$$y = \sqrt{1 - u^2} \sin\theta \tag{5}$$

$$z = u, \tag{6}$$

with $\theta \in [0, 2\pi)$ and $u \in [-1, 1]$, which are also uniformly distributed over $\mathbb{S}^2$.

Marsaglia (1972) derived an elegant method that consists of picking x_1 and x_2 from independent uniform distributions on $(-1, 1)$ and rejecting points for which $x_1^2 + x_2^2 \geq 1$. From the remaining points,

$$x = 2x_1 \sqrt{1 - x_1^2 - x_2^2} \tag{7}$$

$$y = 2x_2 \sqrt{1 - x_1^2 - x_2^2} \tag{8}$$

$$z = 1 - 2(x_1^2 + x_2^2) \quad (9)$$

have a uniform distribution on the surface of a unit sphere. This method can also be extended to HYPERSPHERE POINT PICKING. The plots above show the distribution of points for 100, 1000, and 5000 initial points (where the counts refers to the number of points before throwing away).

Cook (1957) extended a method of von Neumann (1951) to give a simple method of picking points uniformly distributed on the surface of a UNIT SPHERE. Pick four numbers x_0, x_1, x_2, and x_3 from a UNIFORM DISTRIBUTION on $(-1, 1)$, and reject pairs with

$$x_0^2 + x_1^2 + x_2^2 + x_3^2 \geq 1. \quad (10)$$

From the remaining points, the rules of QUATERNION transformation then imply that the points with CARTESIAN COORDINATES

$$x = \frac{2(x_1 x_3 + x_0 x_2)}{x_0^2 + x_1^2 + x_2^2 + x_3^2} \quad (11)$$

$$y = \frac{2(x_2 x_3 - x_0 x_1)}{x_0^2 + x_1^2 + x_2^2 + x_3^2} \quad (12)$$

$$z = \frac{x_0^2 + x_3^2 - x_1^2 - x_2^2}{x_0^2 + x_1^2 + x_2^2 + x_3^2} \quad (13)$$

have the desired distribution (Cook 1957, Marsaglia 1972). The plots above show the distribution of points for 100, 1000, and 5000 initial points (where the counts refers to the number of points before throwing away).

Another easy way to pick a random point on a SPHERE is to generate three Gaussian random variables x, y, and z. Then the distribution of the vectors

$$\frac{1}{\sqrt{x^2 + y^2 + z^2}} \begin{bmatrix} x \\ y \\ z \end{bmatrix} \quad (14)$$

is uniform over the surface $\mathbb{S}^2$ (Muller 1959, Marsaglia 1972).

Sphere Tetrahedron Picking

Pick four points on a sphere. What is the probability that the TETRAHEDRON having these points as VERTICES contains the CENTER of the sphere? In the 1-D case, the probability that a second point is on the opposite side of 1/2 is 1/2. In the 2-D case, pick two points. In order for the third to form a TRIANGLE containing the CENTER, it must lie in the quadrant bisected by a LINE SEGMENT passing through the center of the CIRCLE and the bisector of the two points. This happens for one QUADRANT, so the probability is 1/4. Similarly, for a sphere the probability is one OCTANT, or 1/8.

Pick four points at random on the surface of a unit SPHERE using

$$x = \sqrt{1 - u^2} \cos\theta \quad (1)$$

$$y = \sqrt{1 - u^2} \sin\theta \quad (2)$$

$$z = u \quad (3)$$

with $u \in [-1, 1]$ and $\theta \in [0, \pi)$. Now find the distribution of possible VOLUMES of the (nonregular) TETRAHEDRA determined by these points. Without loss of generality, the first point may be taken as $u_1 = 1$, or $(0, 0, 1)$, while the second may be taken as $(0, u_2)$, or $\left(\sqrt{1 - u_2^2}, 0, u_2\right)$. The average VOLUME is then

$$\bar{V} = \frac{f_{-1}^1 f_{-1}^1 f_{-1}^1 f_{-1}^1 \int_0^{2x} \int_0^{2x} |V(x_i)| \, du_2 \, du_3 \, du_4 \, d\theta_3 \, d\theta_4}{f_{-1}^1 f_{-1}^1 f_{-1}^1 f_{-1}^1 \int_0^{2x} \int_0^{2x} du_2 \, du_3 u_4 \, d\theta_3 \, d\theta_4}, \quad (4)$$

where the VERTICES are located at $\{x_i, y_i, z_i\}$ where $i = 1, \ldots, 4$, and the (signed) VOLUME is given by the DETERMINANT

$$V = \frac{1}{3!}\begin{vmatrix} x_1 & y_1 & z_1 & 1 \\ x_2 & y_2 & z_2 & 1 \\ x_3 & y_3 & z_3 & 1 \\ x_4 & y_4 & z_4 & 1 \end{vmatrix}. \tag{5}$$

The analytic result is difficult to compute, but is numerically given by $\bar{V} \approx 0.120$.

Sphere with Tunnel

Find the tunnel between two points A and B on a gravitating sphere which gives the shortest transit time under the force of gravity. Assume the sphere to be nonrotating, of radius a, and with uniform density ρ. Then the standard form Euler-Lagrange differential equation in polar coordinates is

$$r_{\phi\phi}(r^3 - ra^2) + r_\phi^2(2a^2 - r^2) + a^2r^2 = 0. \tag{1}$$

along with the boundary conditions $r(\phi = 0) = r_0$, $r_\phi(\phi = 0) = 0$, $r(\phi = \phi_A) = a$, and $r(\phi = \phi_B) = a$. Integrating once gives

$$r_\phi^2 = \frac{a^2r^2}{r_0^2}\frac{r^2 - r_0^2}{a^2 - r^2}. \tag{2}$$

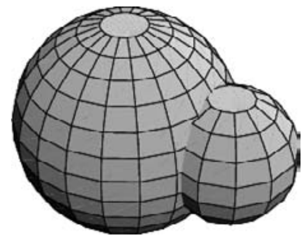
But this is the equation of a hypocycloid generated by a circle of radius $\frac{1}{2}(a - r_0)$ rolling inside the circle of radius a, so the tunnel is shaped like an arc of a hypocycloid. The transit time from point A to point B is

$$T = \pi\sqrt{\frac{a^2 - r_0^2}{ag}}, \tag{3}$$

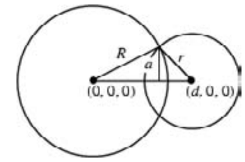
where

$$g = \frac{GM}{a^2} = \tfrac{4}{3}\pi\rho G a \tag{4}$$

is the surface gravity with G the universal gravitational constant.



Sphere-Cone Intersection



Cone-Sphere Intersection

Sphere-Cylinder Intersection

Cylinder-Sphere Intersection

Sphere-Sphere Intersection

Let two spheres of radii R and r be located along the x-axis centered at (0, 0, 0) and (d, 0, 0), respectively. Not surprisingly, the analysis is very similar to the case of the circle-circle intersection. The equations of the two spheres are

$$x^2 + y^2 + z^2 = R^2 \tag{1}$$

$$(x - d)^2 + y^2 + z^2 = r^2. \tag{2}$$

Combining (1) and (2) gives

$$(x - d)^2 + (R^2 - x^2) = r^2. \tag{3}$$

Multiplying through and rearranging give

$$x^2 - 2dx + d^2 - x^2 = r^2 - R^2. \tag{4}$$

Solving for x gives

$$x = \frac{d^2 - r^2 + R^2}{2d}. \tag{5}$$

The intersection of the spheres is therefore a curve lying in a plane parallel to the yz-plane at a single x-coordinate. Plugging this back into (1) gives

$$y^2 + z^2 = R^2 - x^2 = R^2 - \left(\frac{d^2 - r^2 + R^2}{2d}\right)^2$$
$$= \frac{4d^2B^2 - (d^2 - r^2 + R^2)^2}{4d^2}. \tag{6}$$

which is a circle with radius

$$a = \frac{1}{2d}\sqrt{4d^2R^2 - (d^2 - r^2 + R^2)^2}$$
$$= \frac{1}{2d}[(-d + r - R)(-d - r + R)(-d + r + R)$$
$$\times (d + r + R)]^{1/2}. \tag{7}$$

The volume of the 3-D lens common to the two spheres can be found by adding the two spherical caps. The distances from the spheres' centers to the bases of the caps are

$$d_1 = x \tag{8}$$

$$d_2 = d - x, \tag{9}$$

so the heights of the caps are

$$h_1 = R - d_1 = \frac{(r - R + d)(r + R - d)}{2d} \tag{10}$$

$$h_2 = r - d_2 = \frac{(R - r + d)(R + r - d)}{2d}. \tag{11}$$

The VOLUME of a SPHERICAL CAP of height h' for a SPHERE of RADIUS R' is

$$V(R', h') = \tfrac{1}{3}\pi h'^2(3R' - h'). \tag{12}$$

Letting $R_1 = R$ and $R_2 = r$ and summing the two caps gives

$$V = V(R_1, h_1) + V(R_2, h_2)$$
$$= \frac{\pi(R + r - d)^2(d^2 + 2dr - 3r^2 + 2dR + 6rR - 3R^2)}{12d}. \tag{13}$$

This expression gives $V = 0$ for $d = r + R$ as it must. In the special case $r = R$, the VOLUME simplifies to

$$V = \tfrac{1}{12}\pi(4R + d)(2R - d)^2. \tag{14}$$

The SURFACE AREA of the sphere R that lies inside the sphere r is equal to the GREAT CIRCLE of the sphere r, provided that $r \le 2R$ (Kern and Blank 1948, p. 97).

Kern, W. F. and Bland, J. R. *Solid Mensuration with Proofs, 2nd ed.* New York: Wiley, p. 97, 1948.

Spherical Bessel Differential Equation

Take the HELMHOLTZ DIFFERENTIAL EQUATION

$$\nabla^2 F + k^2 F = 0 \tag{1}$$

in SPHERICAL COORDINATES. This is just LAPLACE'S EQUATION in SPHERICAL COORDINATES with an additional term,

$$\frac{d^2R}{dr^2}\Phi\Theta = \frac{2}{r}\frac{dR}{dr}\Phi\Theta + \frac{1}{r^2\sin^2\phi}\frac{d^2\Theta}{d\theta^2}\Phi R$$
$$+\frac{\cos\phi}{r^2\sin\phi}\frac{d\Phi}{d\phi}\Theta R + \frac{1}{r^2}\frac{d^2\Phi}{d\phi^2}\Theta R + k^2 R\Phi\Theta = 0. \tag{2}$$

Multiply through by $r^2/R\Phi\Theta$,

$$\frac{r^2}{R}\frac{d^2R}{dr^2} + \frac{2r}{R}\frac{dR}{dr} + k^2r^2 + \frac{1}{\Theta\sin^2\phi}\frac{d^2\Theta}{d\theta^2} + \frac{\cos\phi}{\Phi\sin\phi}\frac{d\Phi}{d\phi}$$
$$+\frac{1}{\Phi}\frac{d^2\Phi}{d\phi^2} = 0. \tag{3}$$

This equation is separable in R. Call the separation constant $n(n+1)$,

$$\frac{r^2}{R}\frac{d^2R}{dr^2} + \frac{2r}{R}\frac{dR}{dr} + k^2r^2 = n(n+1). \tag{4}$$

Now multiply through by R,

$$r^2\frac{d^2R}{dr^2} + 2r\frac{dR}{dr} + [k^2r^2 - n(n+1)]R = 0. \tag{5}$$

This is the SPHERICAL BESSEL DIFFERENTIAL EQUATION. It can be transformed by letting $x \equiv kr$, then

$$r\frac{dR(r)}{dr} = kr\frac{dR(r)}{k\,dr} = kr\frac{dR(r)}{d(kr)} = x\frac{dR(r)}{dx}. \tag{6}$$

Similarly,

$$r^2\frac{d^2R(r)}{dr^2} = x^2\frac{d^2R(r)}{dx^2}. \tag{7}$$

so the equation becomes

$$x^2\frac{d^2R}{dx^2} = 2x\frac{dR}{dx} + [x^2 - n(n+1)]R = 0. \tag{8}$$

Now look for a solution OF THE FORM $R(r) = Z(x)x^{-1/2}$, denoting a derivative with respect to x by a prime,

$$R' = Z'x^{-1/2} - \tfrac{1}{2}Zx^{-3/2} \tag{9}$$

$$R'' = Z''x^{-1/2} - \tfrac{1}{2}Z'x^{-3/2} - \tfrac{1}{2}Z'x^{-3/2} - \tfrac{1}{2}\left(-\tfrac{3}{2}\right)Zx^{-5/2}$$
$$= Z''x^{-1/2} - Z'x^{-3/2} + \tfrac{3}{4}Zx^{-5/2} \tag{10}$$

so

$$x^2\left(Z''x^{-1/2} - Z'x^{-3/2} + \tfrac{3}{4}Zx^{-5/2}\right)$$
$$+2x\left(Z'x^{-1/2} - \tfrac{1}{2}Zx^{-3/2}\right) + [x^2 - n(n+1)]Zx^{-1/2} = 0 \tag{11}$$

$$x^2\left(Z'' - Z'x^{-1} + \tfrac{3}{4}Zx^{-2}\right) + 2x\left(Z' - \tfrac{1}{2}Zx^{-1}\right)$$
$$+[x^2 - n(n+1)]Z = 0 \tag{12}$$

$$x^2Z'' + (-x + 2x)Z' + \left[\tfrac{3}{4} - 1 + x^2 - n(n+1)\right]Z = 0 \tag{13}$$

$$x^2Z'' + xZ' + \left[x^2 - \left(n^2 + n + \tfrac{1}{4}\right)\right]Z = 0 \tag{14}$$

$$x^2Z'' + xZ' + \left[x^2 - \left(n + \tfrac{1}{2}\right)^2\right]Z = 0. \tag{15}$$

But the solutions to this equation are BESSEL FUNCTIONS of half integral order, so the normalized solutions to the original equation are

$$R(r) \equiv A \frac{J_{n+1/2}(kr)}{\sqrt{kr}} + B \frac{Y_{n+1/2}(kr)}{\sqrt{kr}} \quad (16)$$

which are known as SPHERICAL BESSEL FUNCTIONS. The two types of solutions are denoted $j_n(x)$ (SPHERICAL BESSEL FUNCTION OF THE FIRST KIND) or $n_n(x)$ (SPHERICAL BESSEL FUNCTION OF THE SECOND KIND), and the general solution is written

$$R(r) = A' j_n(kr) + B' n_n(kr). \quad (17)$$

where

$$j_n(z) \equiv \sqrt{\frac{\pi}{2}} \frac{J_{n+1/2}(z)}{\sqrt{z}} \quad (18)$$

$$n_n(z) \equiv \sqrt{\frac{\pi}{2}} \frac{Y_{n+1/2}(z)}{\sqrt{z}}. \quad (19)$$

Spherical Bessel Function

A solution to the SPHERICAL BESSEL DIFFERENTIAL EQUATION. The two types of solutions are denoted $j_n(x)$ (SPHERICAL BESSEL FUNCTION OF THE FIRST KIND) or $n_n(x)$ (SPHERICAL BESSEL FUNCTION OF THE SECOND KIND).

See also SPHERICAL BESSEL DIFFERENTIAL EQUATION, SPHERICAL BESSEL FUNCTION OF THE FIRST KIND, SPHERICAL BESSEL FUNCTION OF THE SECOND KIND

Spherical Bessel Function of the First Kind

$$j_n(x) \equiv \sqrt{\frac{\pi}{2x}} J_{n+1/2}(x) \quad (1)$$

$$= 2^n x^n \sum_{s=0}^{\infty} \frac{(-1)^s (s+n)!}{s!(2s+2n+1)!} x^{2s} \quad (2)$$

$$= \frac{x^n}{(2n+1)!!} \times \left[1 - \frac{\frac{1}{2}x^2}{1!(2n+3)} + \frac{\left(\frac{1}{2}x^2\right)^2}{2!(2n+3)(2n+5)} + \ldots\right] \quad (3)$$

$$= (-1)^n x^n \left(\frac{d}{x\,dx}\right)^n \frac{\sin x}{x} \quad (4)$$

where $j_n(z)$ is a BESSEL FUNCTION OF THE FIRST KIND. The first few functions are

$$j_0(x) = \frac{\sin x}{x} \quad (5)$$

$$j_1(x) = \frac{\sin x}{x^2} - \frac{\cos x}{x} \quad (6)$$

$$j_2(x) = \left(\frac{3}{x^3} - \frac{1}{x}\right) \sin x - \frac{3}{x^2} \cos x. \quad (7)$$

Spherical Bessel functions are not explicitly implemented in *Mathematica*.

Spherical Bessel Function of the Second Kind

$$n_n(x) \equiv \sqrt{\frac{\pi}{2x}}\, Y_{n+1/2}(x) \tag{1}$$

$$= \frac{(-1)^{n+1}}{2^n x^{n+1}} \sum_{s=0}^{\infty} \frac{(-1)^s (s-n)!}{s!(2s-2n)!} x^{2s} \tag{2}$$

$$= \frac{(-1)^{n+1}}{2^n x^{n+1}} \sum_{s=0}^{\infty} \frac{(-1)^s 4^{n-s} \sqrt{\pi}}{\Gamma(s+1)\Gamma\left(\frac{1}{2}-n+s\right)} \tag{3}$$

$$= -\frac{(2n-1)!!}{x^{n+1}} \times \left[1 - \frac{\frac{1}{2}x^2}{1!(1-2n)} + \frac{\left(\frac{1}{2}x^2\right)^2}{2!(1-2n)(3-2n)} + \ldots\right] \tag{4}$$

$$= (-1)^{n+1} \sqrt{\frac{\pi}{2x}} J_{-n-1/2}(x). \tag{5}$$

where $Y_n(z)$ is a BESSEL FUNCTION OF THE SECOND KIND and $j_n(z)$ is a BESSEL FUNCTION OF THE FIRST KIND.
The first few functions are

$$n_0(x) = -\frac{\cos x}{x} \tag{6}$$

$$n_1(x) = -\frac{\cos x}{x^2} - \frac{\sin x}{x} \tag{7}$$

$$n_2(x) = -\left(\frac{3}{x^3} - \frac{1}{x}\right)\cos x - \frac{3}{x^2}\sin x. \tag{8}$$

Spherical Bessel functions are not explicitly implemented in *Mathematica*.

Spherical Bessel Function of the Third Kind

SPHERICAL HANKEL FUNCTION OF THE FIRST KIND, SPHERICAL HANKEL FUNCTION OF THE SECOND KIND

Spherical Cap

A spherical cap is the region of a SPHERE which lies above (or below) a given PLANE. If the PLANE passes through the CENTER of the SPHERE, the cap is a called a HEMISPHERE, and if the cap is cut by a second PLANE, it is called a SPHERICAL SEGMENT. However, Harris and Stocker (1998) use the term "spherical segment" as a synonym for what is here called a spherical cap and "zone" for SPHERICAL SEGMENT.
Let the SPHERE have RADIUS R, then the VOLUME of a spherical cap of height h and base RADIUS a is given by the equation of a SPHERICAL SEGMENT

$$V_{\text{spherical segment}} = \tfrac{1}{6}\pi h(3a^2 + 3b^2 + h^2) \tag{1}$$

with $b = 0$, giving

$$V_{\text{cap}} = \tfrac{1}{6}\pi h(3a^2 + h^2). \tag{2}$$

Using the PYTHAGOREAN THEOREM gives

$$(R-h)^2 + a^2 = R^2, \tag{3}$$

which can be solved for a^2 as

$$a^2 = 2Rh - h^2. \tag{4}$$

so the radius of the base circle is

$$a = \sqrt{h(2R-h)}. \tag{5}$$

and plugging this in gives the equivalent formula

$$V_{\text{cap}} = \tfrac{1}{3}\pi h^2(3R-h). \tag{6}$$

In terms of the so-called CONTACT ANGLE (the angle

between the normal to the sphere at the bottom of the cap and the base plane)

$$R - h = R \sin \alpha \tag{7}$$

$$\alpha \equiv \sin^{-1}\left(\frac{R-h}{R}\right), \tag{8}$$

so

$$V_{\text{cap}} = \tfrac{1}{3}\pi R^3(2 - 3\sin\alpha + \sin^3\alpha). \tag{9}$$

The CENTROID occurs at a distance

$$\bar{z} = \frac{3(2R-h)^2}{4(3R-h)} \tag{10}$$

above the center of the sphere (Harris and Stocker 1998, p. 107).

Consider a cylindrical box enclosing the cap so that the top of the box is tangent to the top of the SPHERE. Then the enclosing box has VOLUME

$$V_{\text{box}} = \pi a^2 h = \pi(R\cos\alpha)[R(1-\sin\alpha)]$$

$$= \pi R^3(1 - \sin\alpha - \sin^2\alpha + \sin^3\alpha), \tag{11}$$

so the hollow volume between the cap and box is given by

$$V_{\text{box}} - V_{\text{cap}} = \tfrac{1}{3}\pi R^3\left(1 - 3\sin^2\alpha + 2\sin^3\alpha\right). \tag{12}$$

If a second PLANE cuts the cap, the resulting SPHERICAL FRUSTUM is called a SPHERICAL SEGMENT. The SURFACE AREA of the spherical cap is given by the same equation as for a general ZONE:

$$S_{\text{cap}} = 2\pi Rh = \pi(a^2 + h^2). \tag{13}$$

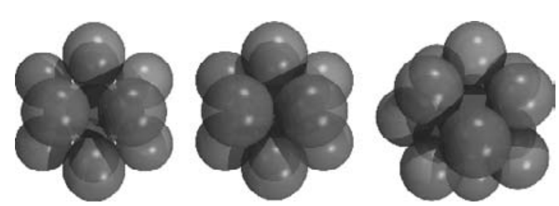
Spherical Code

How can n points be distributed on a UNIT SPHERE such that they maximize the minimum distance between any pair of points? This maximum distance is called the covering radius, and the configuration is called a spherical code (or spherical packing). In 1943, Fejes Tóth proved that for n points, there always exist two points whose distance d is

$$d \leq \sqrt{4 - \csc^2\left[\frac{\pi n}{6(n-2)}\right]},$$

and that the limit is exact for $n = 3$, 4, 6, and 12. The problem of spherical packing is therefore sometimes known as the Fejes Tóth's problem. The general problem has not been solved.

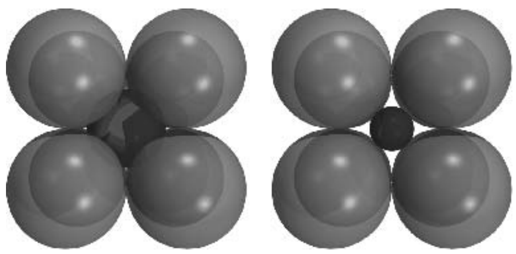
For two points, the points should be at opposite ends of a DIAMETER. For four points, they should be placed at the VERTICES of an inscribed regular TETRAHEDRON. There is no unique best solution for five points since the distance cannot be reduced below that for six points. For six points, they should be placed at the VERTICES of an inscribed regular OCTAHEDRON. For seven points, the best solution is four equilateral spherical triangles with angles of 80°. For eight points, the best dispersal is *not* the VERTICES of the inscribed CUBE, but of a SQUARE ANTIPRISM with equal EDGES. The solution for nine points is eight equilateral spherical triangles with angles of $\cos^{-1}(1/4)$. For 12 points, the solution is an inscribed regular ICOSAHEDRON.



A spherical packing corresponds to the placement of n spheres around a central unit sphere. From simple trigonometry,

$$\sin\left(\tfrac{1}{2}\theta\right) = \frac{r}{1+r}.$$

so the radii of the n spheres are given by



$$r = \frac{1}{\csc\left(\tfrac{1}{2}\theta\right) - 1}$$

for a minimum separation angle of θ. Hardin and Sloane give tables of minimum separations and sphere positions for $n \leq 130$ and $d = 3$, 4, 5.

"Almost" 13 spheres can fit around a central sphere in the sense that there is a gap left over when 12 spheres

are in place which is nearly big enough for an additional sphere (left figure). In fact, the radii of the spheres can be increased to 1.10851 (assuming a central unit sphere) before 12 spheres no longer fit (middle figure). In order to fit 13 spheres around a central unit sphere, their radius must be no larger than 0.916468 (right figure). These values correspond to Hardin and Sloane's angles of 63.4349488° and 57.1367031°, respectively.

Pack eight unit spheres whose centers are at the vertices of a cube. Then the radius of the largest sphere which fits in the center hole (left figure) is given by

$$r_1 = \tfrac{1}{2}(d_1 - 2R)$$

with

$$d_1 = \sqrt{2}(2R),$$

giving

$$r_1 = \left(\sqrt{2} - 1\right)R. \tag{1}$$

Similarly, the radius of the largest sphere which can be passed through from one side to another (right figure) has

$$d_2 = \sqrt{3}(2R),$$

giving

$$r_2 = \tfrac{1}{2}(d_2 - 2R) = \left(\sqrt{3} - 1\right)R. \tag{2}$$

Spherical Cone

spherical cone

The surface of revolution obtained by cutting a conical "wedge" with vertex at the center of a sphere out of the sphere. A spherical cone is therefore a degenerate case of a spherical sector. The volume of the spherical cone is

$$V = \tfrac{2}{3}\pi R^2 h \tag{1}$$

(Kern and Bland 1948, p. 104). The surface area of a closed spherical sector is

$$S = \pi R(2h + r); \tag{2}$$

and the centroid is located at a height

$$\bar{z} = \tfrac{3}{8}(2R - h) \tag{3}$$

above the sphere's center (Harris and Stocker 1998).

Spherical Coordinates

A system of CURVILINEAR COORDINATES which is natural for describing positions on a SPHERE or SPHEROID. Define θ to be the azimuthal ANGLE in the xy-PLANE from the x-AXIS with $0 \le \theta < 2\pi$ (denoted λ when referred to as the LONGITUDE), ϕ to be the POLAR ANGLE from the z-AXIS with $0 \le \phi \le \pi$ (COLATITUDE, equal to $\phi = 90° - \delta$ where δ is the LATITUDE), and r to be distance (RADIUS) from a point to the ORIGIN.

Unfortunately, the convention in which the symbols θ and ϕ are reversed is frequently used, especially in physics, leading to unnecessary confusion. The symbol ρ is sometimes also used in place of r. Arfken (1985) uses (r, ϕ, θ), whereas Beyer (1987) uses (ρ, θ, ϕ). Be very careful when consulting the literature.

In this work, the symbols for the azimuthal, polar, and radial coordinates are taken as θ, ϕ, and r, respectively. Note that this definition provides a logical extension of the usual POLAR COORDINATES notation, with θ remaining the ANGLE in the xy-PLANE and ϕ becoming the ANGLE out of the PLANE.

$$r = \sqrt{x^2 + y^2 + z^2} \tag{1}$$

$$\theta = \tan^{-1}\left(\frac{y}{x}\right) \tag{2}$$

$$\phi = \sin^{-1}\left(\frac{\sqrt{x^2 + y^2}}{r}\right) = \cos^{-1}\left(\frac{z}{r}\right), \tag{3}$$

where $r \in [0, \infty)$, $\theta \in [0, 2\pi)$, and $\phi \in [0, \pi]$. In terms of CARTESIAN COORDINATES,

$$x = r \cos\theta \sin\phi \tag{4}$$

$$y = r \sin\theta \sin\phi \tag{5}$$

$$z = r \cos\phi. \tag{6}$$

The SCALE FACTORS are

$$h_r = 1 \tag{7}$$

$$h_\theta = r \sin\phi \tag{8}$$

$$h_\phi = r, \tag{9}$$

so the METRIC COEFFICIENTS are

$$g_{rr} = 1 \tag{10}$$

$$g_{\theta\theta} = r^2 \sin^2\phi \tag{11}$$

$$g_{\phi\phi} = r^2. \tag{12}$$

The LINE ELEMENT is

$$d\mathbf{s} = dr\,\hat{\mathbf{r}} + r\,d\phi\,\hat{\boldsymbol{\phi}} + r \sin\phi\,d\theta\,\hat{\boldsymbol{\theta}}, \tag{13}$$

the AREA element

$$d\mathbf{a} = r^2 \sin\phi\,d\theta\,d\phi\,\hat{\mathbf{r}}, \tag{14}$$

and the VOLUME ELEMENT

$$dV = r^2 \sin\phi\,d\theta\,d\phi\,dr. \tag{15}$$

The JACOBIAN is

$$\left|\frac{\partial(x, y, z)}{\partial(r, \theta, \phi)}\right| = r^2|\sin\phi|. \tag{16}$$

The POSITION VECTOR is

$$\mathbf{r} \equiv \begin{bmatrix} r\cos\theta\sin\phi \\ r\sin\theta\sin\phi \\ r\cos\phi \end{bmatrix}, \tag{17}$$

so the UNIT VECTORS are

$$\hat{\mathbf{r}} \equiv \frac{\frac{d\mathbf{r}}{dr}}{\left|\frac{d\mathbf{r}}{dr}\right|} = \begin{bmatrix} \cos\theta\sin\phi \\ \sin\theta\sin\phi \\ \cos\phi \end{bmatrix} \tag{18}$$

$$\hat{\boldsymbol{\theta}} \equiv \frac{\frac{d\mathbf{r}}{d\theta}}{\left|\frac{d\mathbf{r}}{d\theta}\right|} = \begin{bmatrix} -\sin\theta \\ \cos\theta \\ 0 \end{bmatrix} \tag{19}$$

$$\hat{\boldsymbol{\phi}} \equiv \frac{\frac{d\mathbf{r}}{d\phi}}{\left|\frac{d\mathbf{r}}{d\phi}\right|} = \begin{bmatrix} \cos\theta\cos\phi \\ \sin\theta\cos\phi \\ -\sin\phi \end{bmatrix}. \tag{20}$$

Derivatives of the UNIT VECTORS are

$$\frac{\partial\hat{\mathbf{r}}}{\partial r} = \mathbf{0} \tag{21}$$

$$\frac{\partial\hat{\boldsymbol{\theta}}}{\partial r} = \mathbf{0} \tag{22}$$

$$\frac{\partial\hat{\boldsymbol{\phi}}}{\partial r} = \mathbf{0} \tag{23}$$

$$\frac{\partial \hat{\mathbf{r}}}{\partial \theta} = \begin{bmatrix} -\sin\theta \sin\phi \\ \cos\theta \sin\phi \\ 0 \end{bmatrix} = \sin\phi\, \hat{\boldsymbol{\theta}} \tag{24}$$

$$\frac{\partial \hat{\boldsymbol{\theta}}}{\partial \theta} = \begin{bmatrix} -\cos\theta \\ -\sin\theta \\ 0 \end{bmatrix} = -\cos\phi\, \hat{\boldsymbol{\phi}} - \sin\phi \hat{\mathbf{r}} \tag{25}$$

$$\frac{\partial \hat{\boldsymbol{\phi}}}{\partial \theta} = \begin{bmatrix} -\sin\theta \cos\phi \\ \cos\theta \cos\phi \\ 0 \end{bmatrix} = \cos\phi\, \hat{\boldsymbol{\theta}} \tag{26}$$

$$\frac{\partial \hat{\mathbf{r}}}{\partial \phi} = \begin{bmatrix} \cos\theta \\ \sin\theta \cos\phi \\ -\sin\phi \end{bmatrix} = \hat{\boldsymbol{\phi}} \tag{27}$$

$$\frac{\partial \hat{\boldsymbol{\theta}}}{\partial \phi} = \mathbf{0} \tag{28}$$

$$\frac{\partial \hat{\boldsymbol{\phi}}}{\partial \phi} = \begin{bmatrix} -\cos\theta \sin\phi \\ -\sin\theta \sin\phi \\ -\cos\phi \end{bmatrix} = -\hat{\mathbf{r}}. \tag{29}$$

The GRADIENT is

$$\nabla = \hat{\mathbf{r}} \frac{\partial}{\partial r} + \frac{1}{r} \hat{\boldsymbol{\phi}} \frac{\partial}{\partial \phi} + \frac{1}{r \sin\phi} \hat{\boldsymbol{\theta}} \frac{\partial}{\partial \theta}, \tag{30}$$

so

$$\nabla_r \hat{\mathbf{r}} = \mathbf{0} \tag{31}$$

$$\nabla_{\mathbf{r}} \hat{\boldsymbol{\theta}} = \mathbf{0} \tag{32}$$

$$\nabla_r \hat{\boldsymbol{\phi}} = \hat{\mathbf{0}} \tag{33}$$

$$\nabla_r \hat{\mathbf{r}} = \frac{\sin\phi\, \hat{\boldsymbol{\theta}}}{r \sin\phi} = \frac{1}{r} \hat{\boldsymbol{\theta}} \tag{34}$$

$$\nabla_\theta \hat{\boldsymbol{\theta}} = -\frac{\cos\phi \hat{\boldsymbol{\phi}} + \sin\phi \hat{\mathbf{r}}}{r \sin\phi} = -\frac{\cot\phi}{r} \hat{\boldsymbol{\phi}} - \frac{1}{r} \hat{\mathbf{r}} \tag{35}$$

$$\nabla_\theta \hat{\boldsymbol{\phi}} = \frac{\cos\phi \hat{\boldsymbol{\phi}}}{r \sin\phi} = \frac{1}{r} \cot\phi \hat{\boldsymbol{\theta}}. \tag{36}$$

Now, since the CONNECTION COEFFICIENTS are given by $\Gamma^i_{jk} = \hat{\mathbf{x}}_i \cdot (\nabla_k \hat{\mathbf{x}}_j)$,

$$\Gamma^\theta = \begin{bmatrix} 0 & \frac{1}{r} & 0 \\ 0 & 0 & 0 \\ 0 & \frac{\cot\phi}{r} & 0 \end{bmatrix} \tag{37}$$

$$\Gamma^\phi = \begin{bmatrix} 0 & 0 & \frac{1}{r} \\ 0 & -\frac{\cot\phi}{r} & 0 \\ 0 & 0 & 0 \end{bmatrix} \tag{38}$$

$$\Gamma^r = \begin{bmatrix} 0 & 0 & 0 \\ 0 & -\frac{1}{r} & 0 \\ 0 & 0 & -\frac{1}{r} \end{bmatrix}. \tag{39}$$

The DIVERGENCE is

$$\begin{aligned} \nabla \cdot \mathbf{F} &= A^k{}_{,k} + \Gamma^k_{jk} A^j \\ &= \left[A^r{}_{,r} + \left(\Gamma^r_{rr} A^r + \Gamma^r_{\theta r} A^\theta + \Gamma^r_{\phi r} A^\phi\right]\right. \\ &\quad + \left[A^\theta{}_{,\theta} + \left(\Gamma^\theta_{r\theta} A^r + \Gamma^\theta_{\theta\theta} A^\theta + \Gamma^\theta_{\phi\theta} A^\phi\right)\right] \\ &\quad + \left[A^\phi{}_{,\phi} + \left(\Gamma^\phi_{r\phi} A^r + \Gamma^\phi_{\theta\phi} A^\theta + \Gamma^\phi_{\phi\phi} A^\phi\right)\right] \\ &= \frac{1}{gr} \frac{\partial A^r}{\partial r} + \frac{1}{g\theta} \frac{\partial A^\theta}{\partial \theta} + \frac{1}{g\phi} \frac{\partial A^\phi}{\partial \phi} + (0+0+0) \\ &\quad + \left(\frac{1}{r} A^r + 0 + \frac{\cot\phi}{r} A^\phi\right) \left(\frac{1}{r} A^r + 0 + 0\right) \\ &= \frac{\partial}{\partial r} A^r + \frac{2}{r} A^r + \frac{1}{r \sin\phi} \frac{\partial}{\partial \theta} A^\theta + \frac{1}{r} \frac{\partial}{\partial \phi} A^\phi \\ &\quad + \frac{\cot\phi}{r} A^\phi, \end{aligned} \tag{40}$$

or, in VECTOR notation,

$$\begin{aligned} \nabla \cdot \mathbf{F} &= \left(\frac{2}{r} + \frac{\partial}{\partial r}\right) F_r + \left(\frac{1}{r} \frac{\partial}{\partial \phi} + \frac{\cot\phi}{r}\right) F_\phi \\ &\quad + \frac{1}{\sin\phi} \frac{\partial F_\theta}{\partial \theta} \\ &= \frac{1}{r^2} \frac{\partial}{\partial r} (r^2 F_r) + \frac{1}{r \sin\phi} \frac{\partial}{\partial \phi} (\sin\phi F_\phi) \\ &\quad + \frac{1}{r \sin\phi} \frac{\partial F_\theta}{\partial \theta}. \end{aligned} \tag{41}$$

The COVARIANT DERIVATIVES are given by

$$A_{j;k} = \frac{1}{g_{kk}} \frac{\partial A_j}{\partial x_k} - \Gamma^i_{jk} A_i, \tag{42}$$

so

$$A_{r;r} = \frac{\partial A_r}{\partial r} - \Gamma^i_{rr} A_i = \frac{\partial A_r}{\partial r} \tag{43}$$

$$\begin{aligned} A_{r;\theta} &= \frac{1}{r \sin\phi} \frac{\partial A_r}{\partial \theta} - \Gamma^i_{\tau\theta} = \frac{1}{r \sin\phi} \frac{\partial A_r}{\partial \theta} - \Gamma_{r\theta} A_\theta \\ &= \frac{1}{r \sin\phi} \frac{\partial A_r}{\partial \phi} - \frac{A_\theta}{r} \end{aligned} \tag{44}$$

$$A_{r;\phi} = \frac{1}{r}\frac{\partial A_r}{\partial \phi} - \Gamma^i_{r\phi}A_i = \frac{1}{r}\frac{\partial A_r}{\partial \phi} - \Gamma^\phi_{r\phi}A_\phi$$

$$= \frac{1}{r}\left(\frac{\partial A_r}{\partial \phi} - A_\phi\right) \quad (45)$$

$$A_{\theta;r} = \frac{\partial A_\theta}{\partial r} - \Gamma^i_{\theta r}A_i = \frac{\partial A_\theta}{\partial r} \quad (46)$$

$$A_{\theta;\theta} = \frac{1}{r\sin\phi}\frac{\partial A_\theta}{\partial \theta} - \Gamma^i_{\theta\theta}A_i$$

$$= \frac{1}{r\sin\phi}\partial A_\theta \partial\theta - \Gamma^\phi_{\theta\theta}A_\phi - \Gamma^r_{\theta\theta}A_r$$

$$= \frac{1}{r\sin\phi}\frac{\partial A_\theta}{\partial\theta} + \frac{\cot\phi}{r}A_\phi + \frac{A_r}{r} \quad (47)$$

$$A_{\theta;\phi} = \frac{1}{r}\frac{\partial A_\theta}{\partial r} - \Gamma^i_{\phi r}A_i \frac{\partial A_\theta}{\partial \phi} \quad (48)$$

$$A_{\phi;r} = \frac{\partial A_\phi}{\partial r} - \Gamma^i_{\phi r}A_i = \frac{\partial A_\phi}{r} \quad (49)$$

$$A_{\phi;\theta} = \frac{1}{r\sin\phi}\frac{\partial A_\phi}{\partial\theta} - \Gamma^i_{\phi\theta}A_i = \frac{1}{r\sin\phi}\frac{\partial A_\phi}{\partial\theta} - \Gamma^\theta_{\phi\theta}$$

$$= \frac{1}{r\sin\phi}\frac{\partial A_\phi}{\partial\theta} - \frac{\cot\phi}{r}A_\theta \quad (50)$$

$$A_{\phi;\phi} = \frac{1}{r}\frac{\partial A_\phi}{\partial\phi} - \Gamma^i_{\phi\phi}A_i = \frac{1}{r}\frac{\partial A_\phi}{\partial\phi} - \Gamma^r_{\phi\phi}A_r$$

$$= \frac{1}{r}\frac{\partial A_\phi}{\partial\phi} + \frac{A_r}{r}. \quad (51)$$

The COMMUTATION COEFFICIENTS are given by

$$c^\mu_{\alpha\beta}\vec{e}_\mu = [\vec{e}_\alpha, \vec{e}_\beta] = \nabla_\alpha\vec{e}_\beta - \nabla_\beta\vec{e}_\alpha \quad (52)$$

$$[\hat{\mathbf{r}}, \hat{\mathbf{r}}] = [\hat{\boldsymbol{\theta}}, \hat{\boldsymbol{\theta}}] = [\hat{\boldsymbol{\phi}}, \hat{\boldsymbol{\phi}}] = \mathbf{0}, \quad (53)$$

so $c^\alpha_{rr} = c^\alpha_{\theta\theta} = c^\alpha_{\phi\phi} = 0$, where $\alpha = r, \theta, \phi$.

$$[\hat{\mathbf{r}}, \hat{\boldsymbol{\theta}}] = -[\hat{\boldsymbol{\theta}}, \hat{\mathbf{r}}] = \nabla_r\hat{\boldsymbol{\theta}} - \nabla_\theta\hat{\mathbf{r}} = \mathbf{0} - \frac{1}{r}\hat{\boldsymbol{\theta}} = -\frac{1}{r}\hat{\boldsymbol{\theta}}. \quad (54)$$

so $c^\theta_{r\theta} = -c^\theta_{\theta r} = -\frac{1}{r}$, $c^r_{r\theta} = c^\phi_{r\theta} = 0$.

$$[\hat{\mathbf{r}}, \hat{\boldsymbol{\phi}}] = -[\hat{\boldsymbol{\phi}}, \hat{\mathbf{r}}] = \mathbf{0} - \frac{1}{r}\hat{\boldsymbol{\phi}} = -\frac{1}{r}\hat{\boldsymbol{\phi}}, \quad (55)$$

so $c^\phi_{r\phi} = -c^\phi_{\phi r} = \frac{1}{r}$.

$$[\hat{\boldsymbol{\theta}}, \hat{\boldsymbol{\phi}}] = -[\hat{\boldsymbol{\phi}}, \hat{\boldsymbol{\theta}}] = \frac{1}{r}\cot\phi\hat{\boldsymbol{\theta}} - \mathbf{0} = \frac{1}{r}\cot\phi\hat{\boldsymbol{\theta}}. \quad (56)$$

so

$$c^\theta_{\theta\phi} = -c^\theta_{\phi\theta} = \frac{1}{r}\cot\phi. \quad (57)$$

Summarizing,

$$c^r = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \quad (58)$$

$$c^\theta = \begin{bmatrix} 0 & -\frac{1}{r} & 0 \\ \frac{1}{r} & 0 & \frac{1}{r}\cot\phi \\ 0 & -\frac{1}{r}\cot\phi & 0 \end{bmatrix} \quad (59)$$

$$c^\phi = \begin{bmatrix} 0 & 0 & -\frac{1}{r} \\ 0 & 0 & 0 \\ \frac{1}{r} & 0 & 0 \end{bmatrix}. \quad (60)$$

Time derivatives of the POSITION VECTOR are

$$\dot{\mathbf{r}} = \begin{bmatrix} \cos\theta\sin\phi\,\dot{r} - r\sin\theta\sin\phi\dot{\theta} + r\cos\theta\cos\phi\dot{\phi} \\ \sin\theta\sin\phi\,\dot{r} + r\cos\theta\sin\phi\dot{\theta} + r\sin\theta\cos\phi\dot{\phi} \\ \cos\phi\dot{r} - r\sin\phi\dot{\phi} \end{bmatrix}$$

$$= \begin{bmatrix} \cos\theta\sin\phi \\ \sin\theta\sin\phi \\ \cos\phi \end{bmatrix}\dot{r} + r\sin\phi\begin{bmatrix} -\sin\theta \\ \cos\theta \\ 0 \end{bmatrix}\dot{\theta}$$

$$+ r\begin{bmatrix} \cos\theta\cos\phi \\ \sin\theta\cos\phi \\ -\sin\phi \end{bmatrix}\dot{\phi}$$

$$= \dot{r}\hat{\mathbf{r}} + r\sin\phi\dot{\theta}\hat{\boldsymbol{\theta}} + r\dot{\phi}\hat{\boldsymbol{\phi}}. \quad (61)$$

The SPEED is therefore given by

$$v \equiv |\dot{\mathbf{r}}| = \sqrt{\dot{r}^2 + r^2\sin^2\phi\dot{\theta}^2 + r^2\dot{\phi}^2}. \quad (62)$$

The ACCELERATION is

$$\ddot{x} = (-\sin\theta\sin\phi\dot{\theta}\dot{r} + \cos\theta\cos\phi\dot{r}\dot{\phi} + \cos\theta\sin\phi\ddot{r})$$

$$-(\sin\theta\sin\phi\dot{r}\dot{\theta} + r\cos\theta\sin\phi\dot{\theta}^2 + r\sin\theta\cos\phi\dot{\theta}\dot{\phi})$$

$$+r\sin\theta\sin\phi\ddot{\theta}) + (\cos\theta\cos\phi\dot{r}\dot{\phi} - r\sin\theta\cos\dot{\theta}\dot{\phi}$$

$$-r\cos\theta\sin\phi\dot{\phi}^2 + r\cos\theta\cos\phi\ddot{\phi})$$

$$= -2\sin\theta\sin\phi\dot{\theta}\dot{r} + 2\cos\theta\cos\phi\dot{r}\dot{\phi}$$
$$- 2r\sin\theta\cos\phi\dot{\theta}\dot{\phi}$$

$$+\cos\theta\sin\phi\ddot{r} - r\sin\theta\sin\phi\ddot{\theta} + r\cos\theta\cos\phi\ddot{\phi}$$

$$-r\cos\theta\sin\phi(\dot{\theta}^2 + \dot{\phi}^2) \quad (63)$$

$$\ddot{y} = (\sin\theta\sin\phi\ddot{r} + r\cos\theta\sin\phi\dot{\theta} + r\cos\phi\sin\theta\dot{\phi})$$

$$+(\cos\theta\sin\phi\dot{r}\dot{\theta} - r\sin\theta\sin\phi\dot{\theta}^2 + r\cos\theta\cos\phi\dot{\theta}\dot{\phi})$$

$$+r\cos\theta\sin\phi\ddot{\theta}) + (\sin\theta\cos\phi\dot{r}\dot{\phi} + r\cos\theta\cos\phi\dot{\theta}\dot{\phi}$$

$$-r\sin\theta\sin\phi\dot{\phi}^2 + r\sin\theta\cos\phi\ddot{\phi}$$

$$= 2\cos\theta\sin\phi\dot{\theta}\dot{r} + 2\sin\theta\cos\phi\dot{r}\dot{\phi} + 2r\cos\theta\cos\phi\dot{\theta}\dot{\phi}$$

$$+\sin\theta\sin\phi\ddot{r}+r\cos\theta\sin\phi\ddot{\theta}+r\sin\theta\cos\phi\ddot{\phi}$$

$$-r\sin\theta\sin\phi\left(\dot{\theta}^2+\dot{\phi}^2\right) \tag{64}$$

$$\ddot{z}=(\cos\phi\ddot{r}-\sin\phi\dot{r}\dot{\phi})$$

$$-(\dot{r}\sin\phi\dot{\phi}+r\cos\phi\dot{\phi}^2+r\sin\phi\ddot{\phi})$$

$$=-r\cos\phi\dot{\phi}^2+\cos\phi\ddot{r}-2\sin\phi\dot{\phi}\dot{r}-r\sin\phi\ddot{\phi}. \tag{65}$$

Plugging these in gives

$$\ddot{\mathbf{r}}=\left(\ddot{r}-r\dot{\phi}^2\right)\begin{bmatrix}\cos\theta\sin\phi\\ \sin\theta\sin\phi\\ \cos\phi\end{bmatrix}$$

$$+(2r\cos\phi\dot{\theta}\dot{\phi}+r\sin\phi\ddot{\theta})\begin{bmatrix}-\sin\theta\\ \cos\theta\\ 0\end{bmatrix}$$

$$+(2\dot{r}\dot{\phi}+r\ddot{\phi})\begin{bmatrix}\cos\theta\cos\phi\\ \sin\theta\cos\phi\\ -\sin\phi\end{bmatrix}-r\sin\phi\dot{\theta}^2\begin{bmatrix}\cos\theta\\ \sin\theta\\ 0\end{bmatrix}. \tag{66}$$

but

$$\sin\phi\hat{\mathbf{r}}+\cos\phi\hat{\boldsymbol{\phi}}=\begin{bmatrix}\cos\theta\sin^2\phi+\cos\theta\cos^2\phi\\ \sin\theta\sin^2\phi+\sin\theta\cos^2\phi\\ 0\end{bmatrix}$$

$$=\begin{bmatrix}\cos\theta\\ \sin\theta\\ 0\end{bmatrix} \tag{67}$$

so

$$\ddot{\mathbf{r}}=\left(\ddot{r}-r\dot{\phi}^2\right)\hat{\mathbf{r}}+(2r\cos\phi\dot{\theta}\dot{\phi}+2\sin\phi\dot{\theta}\dot{r}+r\sin\phi\ddot{\theta})\hat{\boldsymbol{\theta}}$$

$$-(2\dot{r}\dot{\phi}-r\ddot{\phi})\hat{\boldsymbol{\phi}}-r\sin\phi\dot{\theta}^2(\sin\phi\hat{\mathbf{r}}+\cos\phi\hat{\boldsymbol{\phi}})$$

$$=(\ddot{r}-r\dot{\phi}^2-r\sin^2\phi\dot{\theta}^2)\hat{\mathbf{r}}$$

$$+(2\sin\phi\dot{\theta}\dot{r}+2r\cos\phi\dot{\theta}\phi+r\sin\phi\ddot{\theta})\hat{\boldsymbol{\theta}}$$

$$+(2\dot{r}\dot{\phi}+r\ddot{\phi}-r\sin\phi\cos\phi\dot{\theta}^2)\hat{\boldsymbol{\phi}}. \tag{68}$$

Time DERIVATIVES of the UNIT VECTORS are

$$\dot{\hat{\mathbf{r}}}=\begin{bmatrix}-\sin\theta\sin\phi\dot{\theta}+\cos\theta\cos\phi\dot{\phi}\\ \cos\theta\sin\phi\dot{\theta}+\sin\theta\cos\phi\dot{\phi}\\ -\sin\phi\dot{\phi}\end{bmatrix}$$

$$=\sin\phi\dot{\theta}\hat{\boldsymbol{\theta}}+\dot{\phi}\hat{\boldsymbol{\phi}} \tag{69}$$

$$\dot{\hat{\boldsymbol{\theta}}}=\begin{bmatrix}-\cos\theta\dot{\theta}\\ -\sin\theta\dot{\theta}\\ 0\end{bmatrix}=-\dot{\theta}\begin{bmatrix}\cos\theta\\ \sin\theta\\ 0\end{bmatrix}$$

$$=-\dot{\theta}(\sin\phi\hat{\mathbf{r}}+\cos\phi\hat{\boldsymbol{\phi}}) \tag{70}$$

$$\dot{\hat{\boldsymbol{\phi}}}=\begin{bmatrix}-\sin\theta\;\cos\phi\dot{\theta}-\cos\theta\sin\phi\dot{\phi}\\ \cos\theta\;\cos\phi\dot{\theta}-\sin\theta\sin\phi\dot{\phi}\\ -\cos\phi\dot{\phi}\end{bmatrix}$$

$$=-\dot{\phi}\hat{\mathbf{r}}+\cos\phi\dot{\theta}\hat{\boldsymbol{\theta}}. \tag{71}$$

The CURL is

$$\nabla\times\mathbf{F}=\frac{1}{r\sin\phi}\left[\frac{\partial}{\partial\phi}(\sin\phi F_\theta)-\frac{\partial F_\phi}{\partial\theta}\right]\hat{\mathbf{r}}$$

$$+\frac{1}{r}\left[\frac{1}{\sin\phi}\frac{\partial F_r}{\partial\theta}-\frac{\partial}{\partial r}(rF_\theta)\right]\hat{\boldsymbol{\phi}}+\frac{1}{r}$$

$$\times\left[\frac{\partial}{\partial r}\left(rF_\phi\right)-\frac{\partial F_r}{\partial\phi}\right]\hat{\boldsymbol{\theta}}. \tag{72}$$

The LAPLACIAN is

$$\nabla^2\equiv\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right)+\frac{1}{r^2\sin^2}\frac{\partial^2}{\partial\theta^2}+\frac{1}{r^2\sin}\frac{\partial}{\partial\phi}$$

$$\times\left(\sin\phi\frac{\partial}{\partial\phi}\right)$$

$$=\frac{1}{r^2}\left(r^2\frac{\partial^2}{\partial r^2}+2r\frac{\partial}{\partial r}\right)+\frac{1}{r^2\sin^2}\frac{\partial^2}{\partial\theta^2}+\frac{1}{r^2\sin\phi}$$

$$\times\left(\cos\phi\frac{\partial}{\partial\phi}+\sin\phi\frac{\partial^2}{\partial\phi^2}\right)$$

$$=\frac{\partial^2}{\partial r^2}+\frac{2}{r}\frac{\partial}{\partial r}+\frac{1}{r^2\sin^2\phi}\frac{\partial^2}{\partial\theta^2}+\frac{\cos\phi}{r^2\sin\phi}\frac{\partial}{\partial\phi}$$

$$+\frac{1}{r^2}\frac{\partial^2}{\partial\phi^2}. \tag{73}$$

The vector LAPLACIAN is

$$\nabla^2\mathrm{v}=$$

$$\begin{bmatrix}\frac{1}{r}\frac{\partial^2(rv_r)}{\partial r^2}+\frac{1}{r^2}\frac{\partial^2 v_r}{\partial\theta^2}+\frac{1}{r^2\sin^2\theta}\frac{\partial^2 v_r}{\partial\phi^2}+\frac{\cot\theta}{r^2}\frac{\partial v_r}{\theta}-\frac{2}{r^2}\frac{\partial v_\theta}{\partial\theta}-\frac{2}{r^2\sin\theta}\frac{\partial v_\phi}{\partial\phi}-\frac{2v_r}{r^2}-\frac{2\cot\theta}{r^2}v_\theta\\ \frac{1}{r}\frac{\partial^2(rv_\theta)}{\partial r^2}+\frac{1}{r^2}\frac{\partial^2 v_\theta}{\partial\theta^2}+\frac{1}{r^2\sin^2\theta}\frac{\partial^2 v_\theta}{\partial\phi^2}+\frac{\cot\theta}{r^2}\frac{\partial v_\theta}{\theta}-\frac{2}{r^2}\frac{2\cot\theta}{r^2\sin\theta}\frac{\partial v_\phi}{\partial\phi}+\frac{2}{r^2}\frac{2v_r}{\partial\theta}-\frac{v_\theta}{r^2\sin^2\theta}\\ \frac{1}{r}\frac{\partial^2\left(rv_\phi\right)}{\partial r^2}+\frac{1}{r^2}\frac{\partial^2 v_\phi a}{\partial\theta^2}+\frac{1}{r^2\sin^2\theta}\frac{\partial^2 v_\phi}{\partial\phi^2}+\frac{\cot\theta}{r^2}\frac{\partial v_\phi}{\partial\theta}+\frac{2}{r^2}\frac{\partial v_r}{\partial\phi}+\frac{2\cot\theta}{r^2\sin\theta}\frac{\partial v_\theta}{\partial\phi}-\frac{v_\phi}{r^2\sin^2\theta}\end{bmatrix}. \tag{74}$$

To express PARTIAL DERIVATIVES with respect to Cartesian axes in terms of PARTIAL DERIVATIVES of the spherical coordinates,

$$\begin{bmatrix}x\\ y\\ z\end{bmatrix}=\begin{bmatrix}r\cos\theta\sin\phi\\ r\sin\theta\sin\phi\\ r\cos\phi\end{bmatrix} \tag{75}$$

$$\begin{bmatrix}dx\\ dy\\ dz\end{bmatrix}=$$

$$\begin{bmatrix}\cos\theta\sin\phi\,dr-r\sin\theta\sin\phi\,d\theta+r\cos\theta\cos\phi\,d\phi\\ \sin\theta\sin\phi\,dr+r\sin\phi\cos\theta\,d\theta+r\sin\theta\cos\phi\,d\phi\\ \cos\phi\,dr-r\sin\phi\,d\phi\end{bmatrix}$$

$$=\begin{bmatrix}\cos\theta\sin\phi & -r\sin\theta\sin\phi & r\cos\theta\cos\phi\\ \sin\theta\sin\phi & r\sin\phi\cos\theta & r\sin\theta\cos\phi\\ \cos\phi & 0 & -r\sin\phi\end{bmatrix}$$

$$\times\begin{bmatrix}dx\\ dy\\ dz\end{bmatrix}. \tag{76}$$

Upon inversion, the result is

$$\begin{bmatrix} dr \\ d\theta \\ d\phi \end{bmatrix} = \begin{bmatrix} \cos\theta\sin\phi & \sin\theta\sin\phi & \cos\phi \\ -\frac{\sin\theta}{r\sin\phi} & \frac{\cos\theta}{r\sin\phi} & 0 \\ \frac{\cos\theta\cos\phi}{r} & \frac{\sin\theta\cos\phi}{r} & -\frac{\sin\phi}{r} \end{bmatrix} \times \begin{bmatrix} dr \\ dy \\ dz \end{bmatrix}. \quad (77)$$

The Cartesian PARTIAL DERIVATIVES in spherical coordinates are therefore

$$\frac{\partial}{\partial x} = \frac{\partial r}{\partial x}\frac{\partial}{\partial r} + \frac{\partial\theta}{\partial x}\frac{\partial}{\partial\theta} + \frac{\partial\phi}{\partial x}\frac{\partial}{\partial\phi}$$

$$= \cos\theta\sin\phi\frac{\partial}{\partial r} - \frac{\sin\theta}{r\sin\phi}\frac{\partial}{\partial\theta} + \frac{\cos\theta\cos\phi}{r}\frac{\partial}{\partial\phi} \quad (78)$$

$$\frac{\partial}{\partial y} = \frac{\partial}{\partial y}\frac{\partial}{\partial r} + \frac{\partial\theta}{\partial y}\frac{\partial}{\partial\theta} + \frac{\partial\phi}{\partial y}\frac{\partial}{\partial\phi}$$

$$= \sin\theta\sin\phi\frac{\partial}{\partial r} + \frac{\cos\theta}{r\sin\phi}\frac{\partial}{\partial\theta} + \frac{\sin\theta\cos\phi}{r}\frac{\partial}{\partial\phi} \quad (79)$$

$$\frac{\partial}{\partial z} = \frac{\partial r}{\partial z}\frac{\partial}{\partial r} + \frac{\partial\theta}{\partial z}\frac{\partial}{\partial\theta} + \frac{\partial\phi}{\partial z}\frac{\partial}{\partial\phi}$$

$$= \cos\phi\frac{\partial}{\partial r} - \frac{\sin\phi}{r}\frac{\partial}{\partial\phi} \quad (80)$$

(Gasiorowicz 1974, pp. 167–68).

The HELMHOLTZ DIFFERENTIAL EQUATION is separable in spherical coordinates.

Spherical Design

X is a spherical t-design in E IFF it is possible to exactly determine the average value on E of any POLYNOMIAL f of degree at most t by sampling f at the points of X. In other words,

$$\frac{1}{\text{volume } E}\int_E f(\xi)\,d\xi = \frac{1}{|X|}\sum_{x\in X} f(x).$$

Spherical t-designs give the placement of n points on a sphere for use in numerical integration with equal weights.

Spherical Excess

The difference between the sum of the angles A, B, and C of a SPHERICAL TRIANGLE and π radians (180°),

$$E = A + B + C - \pi.$$

The notation Δ is sometimes used for spherical excess instead of E, which can cause confusion since it is also frequently used to denote the SURFACE AREA of a SPHERICAL TRIANGLE (Zwillinger 1995, p. 469). The notation $\in$ is also used (Gellert *et al.* 1989, p. 263).

The equation for the spherical excess in terms of the side lengths a, b, and c is known as L'HUILIER'S THEOREM,

$$\tan\left(\tfrac{1}{4}E\right) = \sqrt{\tan\left(\tfrac{1}{2}s\right)\tan\left[\tfrac{1}{2}(s-a)\right]\tan\left[\tfrac{1}{2}(s-b)\right]\tan\left[\tfrac{1}{2}(s-c)\right]},$$

where s is the SEMIPERIMETER.

Spherical Frustum

SPHERICAL SEGMENT

Spherical Geometry

The study of figures on the surface of a SPHERE (such as the SPHERICAL TRIANGLE and SPHERICAL POLYGON), as opposed to the type of geometry studied in PLANE GEOMETRY or SOLID GEOMETRY. In spherical geometry, straight lines are GREAT CIRCLES, so any two lines meet in two points. There are also no parallel lines. The angle between two lines in spherical geometry is the angle between the planes of the corresponding great circles, and a SPHERICAL TRIANGLE is defined by its three angles. There is no concept of similar triangles in spherical geometry.

Spherical Hankel Function of the First Kind

$$h_n^{(1)}(x) \equiv \sqrt{\frac{\pi}{2x}}\, H_{n+1/2}^{(1)}(x) = j_n(x) + i n_n(x),$$

where $H^{(1)}(x)$ is the HANKEL FUNCTION OF THE FIRST KIND and $j_n(x)$ and $n_n(x)$ are the SPHERICAL BESSEL FUNCTIONS OF THE FIRST and SECOND KINDS. Explicitly, the first few are

$$h_0^{(1)}(x) = \frac{1}{x}(\sin x - i\cos x) = -\frac{i}{x}\, e^{ix}$$

$$h_1^{(1)}(x) = e^{ix}\left(-\frac{1}{x} - \frac{i}{x^2}\right)$$

$$h_2^{(1)}(x) = e^{ix}\left(\frac{i}{x} - \frac{3}{x^2} - \frac{3i}{x^3}\right).$$

Spherical Harmonic

The spherical harmonics $Y_l^m(\theta, \phi)$ are the angular portion of the solution to LAPLACE'S EQUATION in SPHERICAL COORDINATES where azimuthal symmetry is not present. Some care must be taken in identifying the notational convention being used. In this entry, θ

is taken as the polar (colatitudinal) coordinate with $\theta \in [0, \pi]$, and ϕ as the azimuthal (longitudinal) coordinate with $\phi \in [0, 2\pi)$. This is the convention normally used in physics, as described by Arfken (1985) and *Mathematica* (in mathematical literature, θ usually denotes the longitudinal coordinate and ϕ the colatitudinal coordinate). Spherical harmonics are implemented in *Mathematica* as `SphericalHarmonicY[l, m, theta, phi]`.

Spherical harmonics satisfy the SPHERICAL HARMONIC DIFFERENTIAL EQUATION, which is given by the angular part of LAPLACE'S EQUATION in SPHERICAL COORDINATES. Writing $F = \Phi(\phi)\Theta(\theta)$ in this equation gives

$$\frac{\Phi(\phi)}{\sin\theta}\frac{d}{d\theta}\left(\sin\theta\frac{d\Theta}{d\theta}\right)+\frac{\Theta(\theta)}{\sin^2\theta}\frac{d^2\Phi(\phi)}{d\phi^2} + l(l+1)\Theta(\theta)\Phi(\phi)=0. \quad (1)$$

Multiplying by $\sin^2\theta/(\Theta\Phi)$ gives

$$\left[\frac{\sin\theta}{\Theta(\theta)}\frac{d}{d\theta}\left(\sin\theta\frac{d\Theta}{d\theta}\right)+l(l+1)\sin^2\theta\right]+\frac{1}{\Phi(\phi)}\frac{d^2\Phi(\phi)}{d\phi^2} = 0. \quad (2)$$

Using SEPARATION OF VARIABLES by equating the ϕ-dependent portion to a constant gives

$$\frac{1}{\Phi(\phi)}\frac{d^2\Phi(\phi)}{d\phi^2}=-m^2, \quad (3)$$

which has solutions

$$\Phi(\phi)=Ae^{-im\phi}+Be^{im\phi}, \quad (4)$$

Plugging in (3) into (2) gives the equation for the θ-dependent portion, whose solution is

$$\Theta(\theta)=P_l^m(\cos\theta), \quad (5)$$

where $m = -1, -(l-1), ..., 0, ..., l-1, l$ and $P_l^m(z)$ is an associated LEGENDRE POLYNOMIAL. The spherical harmonics are then defined by combining $\Phi(\phi)$ and $\Theta(\theta)$,

$$Y_l^m(\theta, \phi) \equiv \sqrt{\frac{2l+1}{4\pi}\frac{(l-m)!}{(l+m)!}}\,P_l^m(\cos\theta)e^{im\phi}. \quad (6)$$

where the normalization is chosen such that

$$\int_0^{2\pi}\int_0^{\pi} Y_l^m(\theta, \phi)\bar{Y}_{l'}^{m'}(\theta, \phi)\sin\theta\, d\theta\, d\phi = \int_0^{2\pi}\int_{-1}^{1} Y_l^m(\theta, \phi)\bar{Y}_{l'}^{m'}(\theta, \phi) d(\cos\theta)\, d\phi = \delta_{mm'}\,\delta_{ll'}. \quad (7)$$

(Arfken 1985, p. 681). Here, $\bar{z}$ denotes the COMPLEX CONJUGATE and δ_{mn} is the KRONECKER DELTA. Sometimes (e.g., Arfken 1985), the CONDON-SHORTLEY PHASE $(-1)^m$ is prepended to the definition of the spherical harmonics.

The spherical harmonics are sometimes separated into their REAL and IMAGINARY PARTS,

$$Y_l^{ms}(\theta, \phi) \equiv \sqrt{\frac{2l+1}{4\pi}\frac{(l-m)!}{(l+m)!}}\,P_l^m(\cos\theta)\sin(m\phi) \quad (8)$$

$$Y_l^{mc}(\theta, \phi) \equiv \sqrt{\frac{2l+1}{4\pi}\frac{(l-m)!}{(l+m)!}}\,P_l^m(\cos\theta)\cos(m\phi). \quad (9)$$

The spherical harmonics obey

$$Y_l^{-l}(\theta, \phi)=\frac{1}{2^l l!}\sqrt{\frac{(2l+1)!}{4\pi}}\sin^l\theta\, e^{-il\phi} \quad (10)$$

$$Y_l^0(\theta, \phi)=\sqrt{\frac{2l+1}{4\pi}}\,P_l(\cos\theta) \quad (11)$$

$$Y_l^{-m}(\theta, \phi)=(-1)^m\bar{Y}_l^m(\theta, \phi), \quad (12)$$

where $P_l(x)$ is a LEGENDRE POLYNOMIAL.

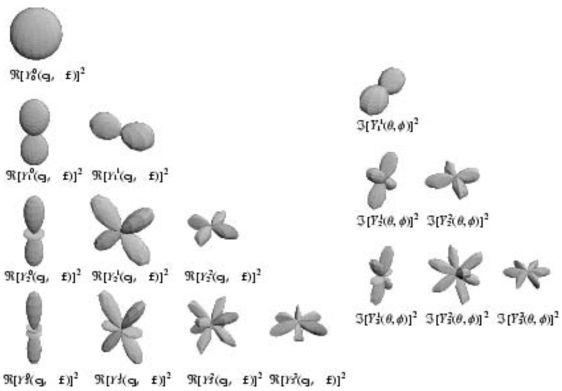
Integrals of the spherical harmonics are given by

$$\int_0^{2\pi}\int_0^{\pi} Y_{l_1}^{m_1}(\theta, \phi)Y_{l_2}^{m_2}(\theta, \phi)Y_{l_3}^{m_3}(\theta, \phi)\sin\theta\, d\theta\, d\phi = \sqrt{\frac{(2l_1+1)(2l_2+1)(2l_3+1)}{4\pi}}\begin{pmatrix} l_1 & l_2 & l_3 \\ 0 & 0 & 0 \end{pmatrix} \times \begin{pmatrix} l_1 & l_2 & l_3 \\ m_1 & m_2 & m_3 \end{pmatrix}, \quad (13)$$

where $\begin{pmatrix} l_1 l_2 l_3 \\ m_1 m_2 m_3 \end{pmatrix}$ is a WIGNER 3*J*-SYMBOL (which is related to the CLEBSCH-GORDAN COEFFICIENTS). Special cases include

$$\int_0^{2\pi}\int_0^{\pi} Y_L^M(\theta, \phi)Y_0^0(\theta, \phi)\bar{Y}_L^M(\theta, \phi)\sin\theta\, d\theta\, d\phi = \frac{1}{\sqrt{2\pi}} \quad (14)$$

$$\int_0^{2\pi}\int_0^{\pi} Y_L^M(\theta, \phi)Y_1^0(\theta, \phi)\bar{Y}_{L+1}^M(\theta, \phi)\sin\theta\, d\theta\, d\phi = \sqrt{\frac{3}{4\pi}}\sqrt{\frac{(L+M+1)(L-M+1)}{(2L+1)(2L+3)}} \quad (15)$$



$$\int_0^{2\pi}\int_0^{\pi} Y_L^M(\theta, \phi)Y_1^1(\theta, \phi)\bar{Y}_{L+1}^{M+1}(\theta, \phi)\sin\theta\, d\theta\, d\phi = \sqrt{\frac{3}{8\pi}}\sqrt{\frac{(L+M+1)(L+M+2)}{(2L+1)(2L+3)}} \quad (16)$$

$$\int_0^{2\pi}\int_0^{\pi} Y_L^M(\theta,\ \phi) Y_1^1(\theta,\ \phi) \bar{Y}_{L-1}^{M+1}(\theta,\ \phi) \sin\theta\, d\theta\, d\phi$$

$$= \sqrt{\frac{3}{8\pi}}\sqrt{\frac{(L-M)(L-M-1)}{(2L-1)(2L+1)}} \tag{17}$$

(Arfken 1985, p. 700).

$111 \xrightarrow{5} 10011 \xrightarrow{2} 1011 \xrightarrow{5} 10101 \xrightarrow{1} 1011 \xrightarrow{2} 111$

The above illustrations show $[Y_l^m(\theta,\ \phi)]^2$ (top), $\Re[Y_l^m(\theta,\ \phi)]^2$ (bottom left), and $\Im[Y_l^m(\theta,\ \phi)]^2$ (bottom right). The first few spherical harmonics are

$$Y_0^0(\theta,\ \phi) = \frac{1}{2}\frac{1}{\sqrt{\pi}}$$

$$Y_1^{-1}(\theta,\ \phi) = \frac{1}{2}\sqrt{\frac{3}{2\pi}} \sin\theta\, e^{-i\phi}$$

$$Y_1^0(\theta,\ \phi) = \frac{1}{2}\sqrt{\frac{3}{\pi}} \cos\theta$$

$$Y_1^1(\theta,\ \phi) = -\frac{1}{2}\sqrt{\frac{3}{2\pi}} \sin\theta\, e^{i\phi}$$

$$Y_2^{-2}(\theta,\ \phi) = \frac{1}{4}\sqrt{\frac{15}{2\pi}} \sin^2\theta\, e^{-2i\phi}$$

$$Y_2^{-1}(\theta,\ \phi) = \frac{1}{2}\sqrt{\frac{15}{2\pi}} \sin\theta\cos\theta\, e^{i\phi}$$

$$Y_2^0(\theta,\ \phi) = \frac{1}{4}\sqrt{\frac{5}{\pi}}(3\cos^2\theta - 1)$$

$$Y_2^1(\theta,\ \phi) = -\frac{1}{2}\sqrt{\frac{15}{2\pi}} \sin\theta\cos\theta\, e^{i\phi}$$

$$Y_2^2(\theta,\ \phi) = \frac{1}{4}\sqrt{\frac{15}{2\pi}} \sin^2\theta\, e^{2i\phi}$$

$$Y_3^{-3}(\theta,\ \phi) = \frac{1}{8}\sqrt{\frac{35}{\pi}} \sin^3\theta\, e^{-3i\phi}$$

$$Y_3^{-2}(\theta,\ \phi) = \frac{1}{4}\sqrt{\frac{105}{2\pi}} \sin^2\theta\cos\theta\, e^{-2i\phi}$$

$$Y_3^{-1}(\theta,\ \phi) = \frac{1}{8}\sqrt{\frac{21}{\pi}} \sin\theta(5\cos^2\theta - 1)e^{-i\phi}$$

$$Y_3^0(\theta,\ \phi) = \frac{1}{4}\sqrt{\frac{7}{\pi}}(5\cos^3\theta - 3\cos\theta)$$

$$Y_3^1(\theta,\ \phi) = -\frac{1}{8}\sqrt{\frac{21}{\pi}} \sin\theta(5\cos^2\theta - 1)e^{i\phi}$$

$$Y_3^2(\theta,\ \phi) = \frac{1}{4}\sqrt{\frac{105}{2\pi}} \sin^2\theta\cos\theta\, e^{2i\phi}$$

$$Y_3^3(\theta,\ \phi) = -\frac{1}{8}\sqrt{\frac{35}{\pi}} \sin^3\theta\, e^{3i\phi}.$$

Written in terms of CARTESIAN COORDINATES,

$$e^{i\phi} = \frac{x+iy}{\sqrt{x^2+y^2}} \tag{18}$$

$$\theta = \sin^{-1}\left(\sqrt{\frac{x^2+y^2}{x^2+y^2+z^2}}\right) \tag{19}$$

$$= \cos^{-1}\left(\frac{z}{\sqrt{x^2+y^2+z^2}}\right), \tag{20}$$

so

$$Y_0^0(\theta,\ \phi) = \frac{1}{2}\frac{1}{\sqrt{\pi}} \tag{21}$$

$$Y_1^0(\theta,\ \phi) = \frac{1}{2}\sqrt{\frac{3}{\pi}}\frac{z}{\sqrt{x^2+y^2+z^2}} \tag{22}$$

$$Y_1^1(\theta,\ \phi) = -\frac{1}{2}\sqrt{\frac{3}{2\pi}}\frac{x+iy}{\sqrt{x^2+y^2+z^2}} \tag{23}$$

$$Y_2^0(\theta,\ \phi) = \frac{1}{4}\sqrt{\frac{5}{\pi}}\left(\frac{3z^2}{x^2+y^2+z^2} - 1\right) \tag{24}$$

$$Y_2^1(\theta,\ \phi) = -\frac{1}{2}\sqrt{\frac{15}{2\pi}}\frac{z(x+iy)}{x^2+y^2+z^2} \tag{25}$$

$$Y_2^2(\theta,\ \phi) = \frac{1}{4}\sqrt{\frac{15}{2\pi}}\frac{(x+iy)^2}{x^2+y^2+z^2}. \tag{26}$$

The ZONAL HARMONICS are defined to be those OF THE FORM

$$P_l^0(\cos\theta) = P_l(\cos\theta). \tag{27}$$

The TESSERAL HARMONICS are those OF THE FORM

$$\sin(m\phi)P_l^m(\cos\theta) \tag{28}$$

$$\cos(m\phi)P_l^m(\cos\theta) \tag{29}$$

for $l \neq m$. The SECTORIAL HARMONICS are OF THE FORM

$$\sin(m\phi)P_m^m(\cos\theta) \tag{30}$$

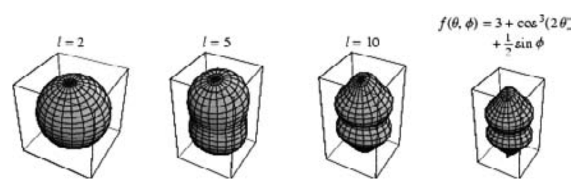
$$\cos(m\phi)P_m^m(\cos\theta). \tag{31}$$

The spherical harmonics form a COMPLETE ORTHONORMAL BASIS, so an arbitrary REAL FUNCTION $f(\theta, \phi)$ can be expanded in terms of complex spherical harmonics by

$$f(\theta, \phi) \equiv \sum_{l=0}^{\infty} \sum_{m=-l}^{l} A_l^m Y_l^m(\theta, \phi). \tag{32}$$

or in terms of real spherical harmonics by

$$f(\theta, \phi) \equiv \sum_{l=0}^{\infty} \sum_{m=0}^{l} [C_l^m Y_l^{mc}(\theta, \phi) + S_l^m Y_l^{ms}(\theta, \phi)]. \tag{33}$$



The process of determining the coefficients A_l^m in (32) is analogous to that to determine the coefficients in a FOURIER SERIES, i.e., multiply both sides of (32) by $\bar{Y}_{l'}^{m'}(\theta, \phi)$, integrate, and use the orthogonality relationship (7) to obtain

$$\int_0^{2\pi}\int_0^{\pi} f(\theta, \phi)\bar{Y}_{l'}^{m'}(\theta, \phi)\sin\theta\, d\theta\, d\phi$$

$$= \sum_{l=0}^{\infty}\sum_{m=-l}^{l}\int_0^{2\pi}\int_0^{\pi} A_l^m Y_l^m \bar{Y}_{l'}^{m'}(\theta, \phi)\sin\theta(\theta, \phi)\, d\theta\, d\phi$$

$$= \sum_{l=1}^{\infty}\sum_{m=-l}^{l} A_l^m \delta_{ll'}\delta_{mm'} = A_l^m. \tag{34}$$

The following sequence of plots shows successive approximations to the function $f(\theta, \phi) = 3 + \cos^3(2\theta) + (\sin\phi)/2$, which is illustrated in the final plot.

Spherical Harmonic Addition Theorem

A FORMULA also known as the LEGENDRE ADDITION THEOREM which is derived by finding GREEN'S FUNCTIONS for the SPHERICAL HARMONIC expansion and equating them to the generating function for LEGENDRE POLYNOMIALS. When γ is defined by

$$\cos\gamma \equiv \cos\theta_1\cos\theta_2 + \sin\theta_1\sin\theta_2\cos(\phi_1 - \phi_2),$$

The LEGENDRE POLYNOMIAL of argument γ is given by

$$P_l(\cos\gamma) = \frac{4\pi}{2l+1}\sum_{m=-l}^{l}(-1)^m Y_l^m(\theta_1, \phi_1)Y_l^{-m}(\theta_2, \phi_2)$$

$$= \frac{4\pi}{2l+1}\sum_{m=-l}^{l} Y_l^m(\theta_1, \phi_1)\bar{Y}_l^m(\theta_2, \phi_2)$$

$$= P_l(\cos\theta_1)P_l(\cos\theta_2)$$

$$+2\sum_{m=1}^{l}\frac{(l-m)!}{(l+m)!}P_l^m(\cos\theta_1)P_l^m(\cos\theta_2)\cos[m(\phi_1-\phi_2)].$$

Spherical Harmonic Closure Relations

The sum of the absolute squares of the SPHERICAL HARMONICS $Y_l^m(\theta,\ \phi)$ over all values of m is

$$\sum_{m=-l}^{l}\left|Y_l^m(\theta,\ \phi)\right|^2=\frac{2l+1}{4\pi}.$$

The double sum over m and l is given by

$$\begin{aligned}\sum_{l=0}^{\infty}\sum_{m=-l}^{l}&Y_l^m(\theta_1,\ \phi_1)\bar{Y}_l^m(\theta_2,\ \phi_2)\\&=\frac{1}{\sin\theta_1}\delta(\theta_1-\theta_2)\delta(\phi_1-\phi_2)\\&=\delta(\cos\theta_1-\cos\theta_2)\delta(\cos\phi_1-\cos\phi_2),\end{aligned}$$

where $\delta(x)$ is the DELTA FUNCTION.

Spherical Harmonic Differential Equation

In three dimensions, the spherical harmonic differential equation is given by

$$\left[\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right)+\frac{1}{\sin^2\theta}\frac{\partial^2}{\partial\phi^2}+l(l+1)\right]u=0,$$

and solutions are called SPHERICAL HARMONICS (Zwillinger 1997, p. 130). In four dimensions, the spherical harmonic differential equation is

$$\begin{aligned}u_{xx}&+2u_x\cot x+\csc^2 x\left(u_{yy}+u_y\cot y+u_{zz}\csc^2 y\right)\\&+\left(n^2-1\right)u=0\end{aligned}$$

(Humi 1987; Zwillinger 1997, p. 130).

Spherical Harmonic Tensor

A tensor defined in terms of the TENSORS which satisfy the DOUBLE CONTRACTION RELATION.

See also DOUBLE CONTRACTION RELATION, SPHERICAL HARMONIC

Spherical Helix

The TANGENT INDICATRIX of a CURVE OF CONSTANT PRECESSION is a spherical helix. The equation of a spherical helix on a SPHERE with RADIUS r making an ANGLE θ with the z-AXIS is

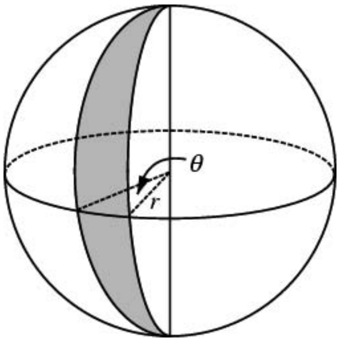
$$\begin{aligned}x(\psi)=&\tfrac{1}{2}r(1+\cos\theta)\cos\psi\\&-\tfrac{1}{2}r(1-\cos\theta)\cos\left(\frac{1+\cos\theta}{1-\cos\theta}\ \psi\right)\end{aligned}\quad(1)$$

$$\begin{aligned}y(\psi)=&\tfrac{1}{2}r(1+\cos\theta)\sin\psi\\&-\tfrac{1}{2}r(1-\sin\theta)\sin\left(\frac{1+\cos\theta}{1-\cos\theta}\ \psi\right)\end{aligned}\quad(2)$$

$$z(\psi)=r\sin\theta\cos\left(\frac{\cos\theta}{1-\cos\theta}\ \psi\right).\quad(3)$$

The projection on the xy-plane is an EPICYCLOID with RADII

$$a=r\cos\theta\quad(4)$$



$$b=r\sin^2\left(\tfrac{1}{2}\theta\right).\quad(5)$$

Spherical Lune

A sliver of the surface of a SPHERE of RADIUS r cut out by two planes through the azimuthal axis with DIHEDRAL ANGLE θ. The SURFACE AREA of the lune is

$$S=2r^2\theta,$$

which is just the area of the SPHERE times $\theta/(2\pi)$. The VOLUME of the associated SPHERICAL WEDGE has

VOLUME

$$V = \frac{2}{3} r^3 \theta.$$

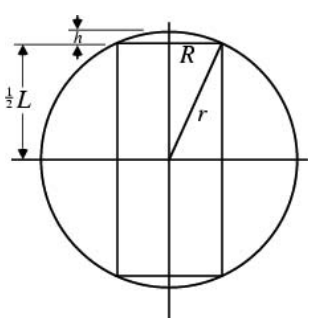
Spherical Packing

SPHERICAL CODE

Spherical Polygon

A closed geometric figure on the surface of a SPHERE which is formed by the ARCS of GREAT CIRCLES. The spherical polygon is a generalization of the SPHERICAL TRIANGLE. If θ is the sum of the RADIAN ANGLES of a spherical polygon on a SPHERE of RADIUS R, then the AREA is



$$S = [\theta - (n-2)\pi]R^2.$$

See also GREAT CIRCLE, SPHERICAL TRIANGLE

References

Beyer, W. H. *CRC Standard Mathematical Tables, 28th ed.* Boca Raton, FL: CRC Press, p. 131, 1987.

Spherical Ring

A SPHERE with a CYLINDRICAL HOLE cut so that the centers of the CYLINDER and SPHERE coincide, also called a NAPKIN RING. Let the SPHERE be of RADIUS r and the CYLINDER of RADIUS R. The VOLUME of the entire CYLINDER is

$$V_{\text{cyl}} = \pi L R^2, \tag{1}$$

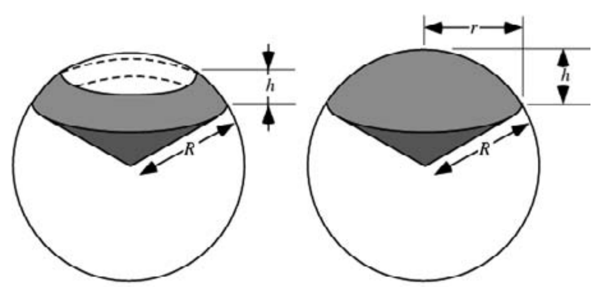
and the VOLUME of the upper segment is

$$V_{\text{seg}} = \frac{1}{6}\pi h\left(3R^2 + h^2\right), \tag{2}$$

where

$$R = \sqrt{r^2 - \frac{1}{4}L^2} \tag{3}$$

$$h = r - \frac{1}{2}L, \tag{4}$$



so the VOLUME removed upon drilling of a CYLINDRICAL hole is

$$\begin{aligned} V_{\text{rem}} = V_{\text{cyl}} + 2V_{\text{seg}} &= \pi\left[LR^2 + \frac{1}{3}h\left(3R^2 + h^2\right)\right] \\ &= \pi\left(LR^2 + hR^2 + \frac{1}{3}h^3\right) \\ &= \pi\left[L\left(r^2 - \frac{1}{4}L^2\right) + \left(r - \frac{1}{2}L\right)\left(r^2 - \frac{1}{4}L^2\right) + \frac{1}{3}\left(r - \frac{1}{2}L\right)^3\right] \\ &= \pi\left[Lr^2 - \frac{1}{4}L^3 + \left(r^3 - \frac{1}{2}r^2L - \frac{1}{4}RL^2 + \frac{1}{8}L^3\right)\right. \\ &\qquad \left. + \frac{1}{3}\left(r^3 - \frac{3}{2}r^2L + \frac{3}{4}rL^2 - \frac{1}{8}L^3\right)\right] \\ &= \pi\left[\frac{4}{3}r^3 + \left(1 - \frac{1}{2} - \frac{1}{2}\right)r^2L + \left(-\frac{1}{4} + \frac{1}{4}\right)RL^2\right. \\ &\qquad \left. + L^3\left(-\frac{1}{4} + \frac{1}{8} - \frac{1}{24}\right)\right] \\ &= \frac{4}{3}\pi r^3 - \frac{1}{6}\pi L^3 = \frac{1}{6}\pi\left(8r^3 - L^3\right), \end{aligned} \tag{5}$$

so

$$\begin{aligned} V_{\text{left}} = V_{\text{sphere}} - V_{\text{rem}} &= \frac{4}{3}\pi r^3 - \left(\frac{4}{3}\pi r^3 - \frac{1}{6}\pi L^3\right) \\ &= \frac{1}{6}\pi L^3. \end{aligned} \tag{6}$$

Spherical Sector

open spherical sector *spherical cone*

A spherical sector is a SOLID OF REVOLUTION enclosed by two radii from the center of a SPHERE. The spherical sector may either be "open" and have a conical HOLE (left figure; Beyer 1987), or may be a "closed" SPHERICAL CONE (right figure; Harris and Stocker 1998). The VOLUME of a spherical sector in

either case is given by

$$V = \tfrac{2}{3}\pi R^2 h,$$

where h is the vertical distance between where the upper and lower radii intersect the sphere and R is the sphere's radius.

See also Cylindrical Segment, Sphere, Spherical Cap, Spherical Cone, Spherical Segment, Spherical Wedge, Zone

References

Smith, D. E. "Spherical Sector." §542 in *Essentials of Plane and Solid Geometry.* Boston, MA: Ginn and Co., p. 542, 1923.

Spherical Segment

A spherical segment is the solid defined by cutting a sphere with a pair of parallel planes. It can be thought of as a spherical cap with the top truncated, and so it corresponds to a spherical frustum. The surface of the spherical segment (excluding the bases) is called a zone. However, Harris and Stocker (1998) use the term "spherical segment" as a synonym for spherical cap and "zone" for what is here called a spherical segment.

Call the radius of the sphere R and the height of the segment (the distance from the plane to the top of sphere) h. Let the radii of the lower and upper bases be denoted a and b, respectively. Call the distance from the center to the start of the segment d, and the height from the bottom to the top of the segment h. Call the radius parallel to the segment r, and the height above the center y. Then $r^2 = R^2 - y^2$,

$$V = \int_d^{d+h} \pi r^2\, dy = \pi \int_d^{d+h} (R^2 - y^2)\, dy$$

$$= \pi\left[R^2 y - \tfrac{1}{3} y^3\right]_d^{d+h} = \pi\left\{R^2 h - \tfrac{1}{3}\left[(d+h)^3 - d^3\right]\right\}$$

$$= \pi\left[R^2 h - \tfrac{1}{3}(d^3 + 3d^2 h + 3h^2 d + h^3 - d^3)\right]$$

$$= \pi h\left(R^2 - d^2 - hd - \tfrac{1}{3} h^2\right), \tag{1}$$

Using

$$a^2 = R^2 - d^2 \tag{2}$$

$$b^2 = R^2 - (d+h)^2 = R^2 - d^2 - 2dh - h^2, \tag{3}$$

gives

$$a^2 + b^2 = 2R^2 - 2d^2 - 2dh - h^2 \tag{4}$$

$$R^2 - d^2 - dh = \tfrac{1}{2}(a^2 + b^2 + h^2), \tag{5}$$

so

$$V = \pi h\left[\tfrac{1}{2}(a^2 + b^2 + h^2) - \tfrac{1}{3} h^2\right] = \pi h\left(\tfrac{1}{2} a^2 + \tfrac{1}{2} b^2 + \tfrac{1}{6} h^2\right)$$

$$= \tfrac{1}{6}\pi h(3a^2 + 3b^2 + h^2). \tag{6}$$

The surface area of the zone (which excludes the top and bottom bases) is given by

$$S = 2\pi R h. \tag{7}$$

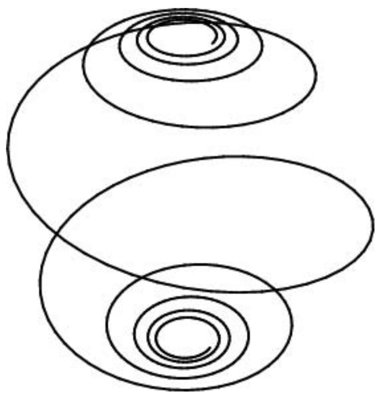
Spherical Shell



A generalization of an annulus to 3-D. A spherical shell is the intersection of two concentric balls of differing radii.

See also Annulus, Ball, Chord, Sphere, Spherical Helix

Spherical Simplex

The only irreducible spherical simplexes generated by reflection are A_n $(n \geq 1)$, B_n $(n \geq 4)$, C_n $(n \geq 2)$, D_2^p $(p \geq 5)$, E_6, E_7, E_8, F_4, G_3, and G_4. The only irreducible Euclidean simplexes generated by reflection are W_2, P_m $(m \geq 3)$, Q_m $(m \geq 5)$, R_m $(m \geq 3)$, S_m $(m \geq 4)$, V_3, T_7, T_8, T_9, and U_5.

Spherical Spiral

The SPHERICAL CURVE taken by a ship which travels from the south pole to the north pole of a SPHERE while keeping a fixed (but not RIGHT) angle with respect to the meridians. The curve has an infinite number of loops since the separation of consecutive revolutions gets smaller and smaller near the poles. It is given by the PARAMETRIC EQUATIONS

$$x = \cos t \cos c$$

$$y = \sin t \cos c$$

$$z = -\sin c,$$

where

$$c \equiv \tan^{-1}(at)$$

and a is a constant, and is a special case of a LOXODROME.

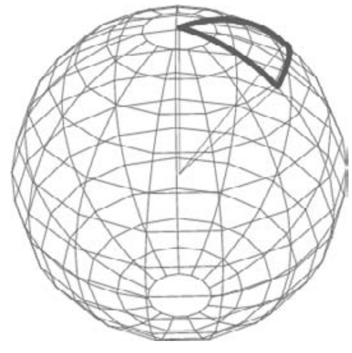
Spherical Symmetry

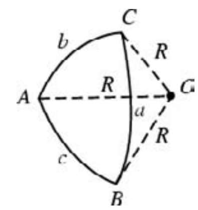
Let **A** and **B** be constant VECTORS. Define

$$Q \equiv 3(\mathbf{A} \cdot \hat{\mathbf{r}})(\mathbf{B} \cdot \hat{\mathbf{r}}) - \mathbf{A} \cdot \mathbf{B}.$$

Then the average of Q over a spherically symmetric surface or volume is



$$\langle Q \rangle = \langle 3 \cos^2 \theta - 1 \rangle (\mathbf{A} \cdot \mathbf{B}) = 0,$$



since $\langle 3 \cos^2 \theta - 1 \rangle = 0$ over the sphere.

Spherical Tessellation

TRIANGULAR SYMMETRY GROUP

Spherical Triangle

A spherical triangle is a figure formed on the surface of a sphere by three great circular arcs intersecting pairwise in three vertices. The spherical triangle is the spherical analog of the planar TRIANGLE, and is sometimes called EULER'S TRIANGLE (Harris and Stocker 1998). Let a spherical triangle have ANGLES A, B, and C (measured in radians at the vertices along the surface of the sphere) and let the sphere on which the spherical triangle sits have RADIUS R. Then the SURFACE AREA Δ of the spherical triangle is

$$\Delta = R^2[(A+B+C) - \pi] = R^2 E,$$

where E is called the SPHERICAL EXCESS, with $E = 0$ in the degenerate case of a planar triangle.

The sum of the angles of a spherical triangle is between π and 3π radians (180° and 540°; Zwillinger 1995, p. 469). The amount by which it exceeds 180° is called the SPHERICAL EXCESS and is denoted E or Δ, the latter of which can cause confusion since it also can refer to the SURFACE AREA of a spherical triangle. The difference between 2π radians (360°) and the sum of the side arc lengths a, b, and c is called the SPHERICAL DEFECT and is denoted D or δ.

The study of angles and distances of figures on a sphere is known as SPHERICAL TRIGONOMETRY.

Spherical Trigonometry

Let a SPHERICAL TRIANGLE be drawn on the surface of a SPHERE of radius R, centered at a point $O=(0, 0, 0)$, with vertices A, B, and C. The vectors from the center of the sphere to the vertices are therefore given by $\mathbf{a}\equiv\overrightarrow{OA}$, $\mathbf{b}\equiv\overrightarrow{OB}$, and $\mathbf{c}\equiv\overrightarrow{OC}$. Now, the *angular* lengths of the sides of the triangle (in radians) are then $a'\equiv\angle BOC$, $b'\equiv\angle COA$, and $c'\equiv\angle AOB$, and the *actual* arc lengths of the side are $a=Ra'$, $b=Rb'$, and $c=Rc'$. Explicitly,

$$\mathbf{a}\cdot\mathbf{b}=R^2\cos c'=R^2\cos\left(\frac{c}{R}\right) \quad (1)$$

$$\mathbf{a}\cdot\mathbf{c}=R^2\cos b'=R^2\cos\left(\frac{b}{R}\right) \quad (2)$$

$$\mathbf{b}\cdot\mathbf{c}=R^2\cos a'=R^2\cos\left(\frac{a}{R}\right). \quad (3)$$

Now make use of A, B, and C to denote both the vertices themselves and the *angles* of the spherical triangle at these vertices, so that the DIHEDRAL ANGLE between PLANES AOB and AOC is written A, the DIHEDRAL ANGLE between PLANES BOC and AOB is written B, and the DIHEDRAL ANGLE between PLANES BOC and AOC is written C. (These angles are sometimes instead denoted α, β, γ; e.g., Gellert *et al.* 1989)

Consider the DIHEDRAL ANGLE A between planes AOB and AOC, which can be calculated using the DOT PRODUCT of the normals to the planes. The normals are given by CROSS PRODUCTS of the vectors to the vertices, so

$$(\hat{\mathbf{a}}\times\hat{\mathbf{b}})\cdot(\hat{\mathbf{a}}\times\hat{\mathbf{c}})=(|\hat{\mathbf{a}}||\hat{\mathbf{b}}|\sin c)(|\hat{\mathbf{a}}||\hat{\mathbf{c}}|\sin b)\cos A$$
$$=\sin b\sin c\cos A. \quad (4)$$

However, using a well-known vector identity gives

$$(\hat{\mathbf{a}}\times\hat{\mathbf{b}})\cdot(\hat{\mathbf{a}}\times\hat{\mathbf{c}})=\hat{\mathbf{a}}\cdot[\hat{\mathbf{b}}\times(\hat{\mathbf{a}}\times\hat{\mathbf{c}})]$$
$$=\hat{\mathbf{a}}\cdot[\hat{\mathbf{a}}(\hat{\mathbf{b}}\cdot\hat{\mathbf{c}})-\hat{\mathbf{c}}(\hat{\mathbf{a}}\cdot\hat{\mathbf{b}})]$$
$$=(\hat{\mathbf{b}}\cdot\hat{\mathbf{c}})-(\hat{\mathbf{a}}\cdot\hat{\mathbf{c}})(\hat{\mathbf{a}}\cdot\hat{\mathbf{b}})$$
$$=\cos a-\cos c\cos b. \quad (5)$$

Since these two expressions must be equal, we obtain the identity (and its two analogous formulas)

$$\cos a=\cos b\cos c+\sin b\sin c\cos A \quad (6)$$

$$\cos b=\cos c\cos a+\sin c\sin a\cos B \quad (7)$$

$$\cos c=\cos a\cos b+\sin a\sin b\cos C. \quad (8)$$

known as the cosine rules for sides (Smart 1960, pp. 7–; Gellert *et al.* 1989, p. 264; Zwillinger 1995, p. 469).

The identity

$$\sin A=\frac{|(\hat{\mathbf{a}}\times\hat{\mathbf{b}})\times(\hat{\mathbf{a}}\times\hat{\mathbf{c}})|}{|\hat{\mathbf{a}}\times\hat{\mathbf{b}}||\hat{\mathbf{a}}\times\hat{\mathbf{c}}|}$$
$$=\frac{|\hat{\mathbf{a}}[\hat{\mathbf{b}},\ \hat{\mathbf{a}},\ \hat{\mathbf{c}}]+\hat{\mathbf{b}}[\hat{\mathbf{a}},\ \hat{\mathbf{a}},\ \hat{\mathbf{c}}]|}{\sin b\sin c}$$
$$=\frac{[\hat{\mathbf{a}},\ \hat{\mathbf{b}},\ \hat{\mathbf{c}}]}{\sin b\sin c}, \quad (9)$$

where $[\mathbf{a},\ \mathbf{b},\ \mathbf{c}]$ is the SCALAR TRIPLE PRODUCT, gives

$$\frac{\sin A}{\sin a}=\frac{[\hat{\mathbf{a}},\ \hat{\mathbf{b}},\ \hat{\mathbf{c}}]}{\sin a\sin b\sin c}, \quad (10)$$

so the spherical analog of the LAW OF SINES can be written

$$\frac{\sin A}{\sin a}=\frac{\sin B}{\sin b}=\frac{\sin C}{\sin c}=\frac{6\ \mathrm{Vol}(OABC)}{\sin a\sin b\sin c} \quad (11)$$

(Smart 1960, pp. 9–0; Gellert *et al.* 1989, p. 265; Zwillinger 1995, p. 469), where Vol($OABC$) is the VOLUME of the TETRAHEDRON.

The analogs of the LAW OF COSINES for the angles of a SPHERICAL TRIANGLE are given by

$$\cos A=-\cos B\cos C+\sin B\sin C\cos a \quad (12)$$

$$\cos B=-\cos C\cos A+\sin C\sin A\cos b \quad (13)$$

$$\cos C=-\cos A\cos B+\sin A\sin B\cos c \quad (14)$$

(Gellert *et al.* 1989, p. 265; Zwillinger 1995, p. 470).

Finally, there are spherical analogs of the LAW OF TANGENTS,

$$\frac{\tan\left[\frac{1}{2}(B-C)\right]}{\tan\left[\frac{1}{2}(B+C)\right]}=\frac{\tan\left[\frac{1}{2}(b-c)\right]}{\tan\left[\frac{1}{2}(b+c)\right]} \quad (15)$$

$$\frac{\tan\left[\frac{1}{2}(C-A)\right]}{\tan\left[\frac{1}{2}(C+A)\right]}=\frac{\tan\left[\frac{1}{2}(c-a)\right]}{\tan\left[\frac{1}{2}(c+a)\right]} \tag{16}$$

$$\frac{\tan\left[\frac{1}{2}(A-B)\right]}{\tan\left[\frac{1}{2}(A+B)\right]}=\frac{\tan\left[\frac{1}{2}(a-b)\right]}{\tan\left[\frac{1}{2}(a+b)\right]} \tag{17}$$

(Beyer 1987; Gellert *et al.* 1989; Zwillinger 1995, p. 470).

Additional important identities are given by

$$\cos A=\csc b\csc c(\cos a-\cos b\cos c). \tag{18}$$

(Smart 1960, p. 8),

$$\sin a\cos B=\cos b\sin c-\sin b\cos c\cos A \tag{19}$$

(Smart 1960, p. 10), and

$$\cos a\cos C=\sin a\cot b-\sin C\cot B \tag{20}$$

(Smart 1960, p. 12).

Let

$$s\equiv\tfrac{1}{2}(a+b+c) \tag{21}$$

be the semiperimeter, then half-angle formulas for sines can be written as

$$\sin\left(\tfrac{1}{2}A\right)=\sqrt{\frac{\sin(s-b)\sin(s-c)}{\sin b\sin c}} \tag{22}$$

$$\sin\left(\tfrac{1}{2}B\right)=\sqrt{\frac{\sin(s-a)\sin(s-c)}{\sin a\sin c}} \tag{23}$$

$$\sin\left(\tfrac{1}{2}C\right)=\sqrt{\frac{\sin(s-a)\sin(s-b)}{\sin a\sin b}}. \tag{24}$$

for cosines can be written as

$$\cos\left(\tfrac{1}{2}A\right)=\sqrt{\frac{\sin s\sin(s-a)}{\sin b\sin c}} \tag{25}$$

$$\cos\left(\tfrac{1}{2}B\right)=\sqrt{\frac{\sin s\sin(s-b)}{\sin a\sin c}} \tag{26}$$

$$\cos\left(\tfrac{1}{2}C\right)=\sqrt{\frac{\sin s\sin(s-c)}{\sin a\sin b}}. \tag{27}$$

and tangents can be written as

$$\tan\left(\tfrac{1}{2}A\right)=\sqrt{\frac{\sin(s-b)\sin(s-c)}{\sin s\sin(s-a)}}=\frac{k}{\sin(s-a)} \tag{28}$$

$$\tan\left(\tfrac{1}{2}B\right)=\sqrt{\frac{\sin(s-a)\sin(s-c)}{\sin s\sin(s-b)}}=\frac{k}{\sin(s-b)} \tag{29}$$

$$\tan\left(\tfrac{1}{2}C\right)=\sqrt{\frac{\sin(s-a)\sin(s-b)}{\sin s\sin(s-c)}}=\frac{k}{\sin(s-c)}, \tag{30}$$

where

$$k^2=\frac{\sin(s-a)\sin(s-b)\sin(s-c)}{\sin s} \tag{31}$$

(Smart 1960, pp. 8–; Gellert *et al.* 1989, p. 265; Zwillinger 1995, p. 470).

Let

$$S\equiv\tfrac{1}{2}(A+B+C) \tag{32}$$

be the sum of half-angles, then the half-side formulas are

$$\tan\left(\tfrac{1}{2}a\right)=K\cos(S-A) \tag{33}$$

$$\tan\left(\tfrac{1}{2}b\right)=K\cos(S-B) \tag{34}$$

$$\tan\left(\tfrac{1}{2}c\right)=K\cos(S-C). \tag{35}$$

where

$$K^2=-\frac{\cos S}{\cos(S-A)\cos(S-B)\cos(S-C)} \tag{36}$$

(Gellert *et al.* 1989, p. 265; Zwillinger 1995, p. 470).

The HAVERSINE formula for sides, where

$$\operatorname{hav}x\equiv\tfrac{1}{2}(1-\cos x)=\sin^2\left(\tfrac{1}{2}x\right), \tag{37}$$

is given by

$$\operatorname{hav}a=\operatorname{hav}(b-c)+\sin b\sin c\operatorname{hav}A \tag{38}$$

(Smart 1960, pp. 18–9; Zwillinger 1995, p. 471), and the HAVERSINE formula for angles is given by

$$\operatorname{hav}A=\frac{\sin(s-b)\sin(s-c)}{\sin b\sin c} \tag{39}$$

$$=\frac{\operatorname{hav}a-\operatorname{hav}(b-c)}{\sin b\sin c} \tag{40}$$

$$=\operatorname{hav}[\pi-(B+C)]+\sin B\sin C\operatorname{hav}a \tag{41}$$

(Zwillinger 1995, p. 471).

GAUSS'S FORMULAS (also called Delambre's analogies) are

$$\frac{\sin\left[\frac{1}{2}(a-b)\right]}{\sin\left(\frac{1}{2}c\right)}=\frac{\sin\left[\frac{1}{2}(A-B)\right]}{\cos\left(\frac{1}{2}C\right)} \tag{42}$$

$$\frac{\sin\left[\frac{1}{2}(a+b)\right]}{\sin\left(\frac{1}{2}c\right)}=\frac{\cos\left[\frac{1}{2}(A-B)\right]}{\sin\left(\frac{1}{2}C\right)} \tag{43}$$

$$\frac{\cos\left[\frac{1}{2}(a-b)\right]}{\cos\left(\frac{1}{2}c\right)}=\frac{\sin\left[\frac{1}{2}(A+B)\right]}{\cos\left(\frac{1}{2}C\right)} \tag{44}$$

$$\frac{\cos\left[\frac{1}{2}(a+b)\right]}{\cos\left(\frac{1}{2}c\right)} = \frac{\cos\left[\frac{1}{2}(A+B)\right]}{\sin\left(\frac{1}{2}C\right)} \tag{45}$$

(Smart 1960, p. 22; Zwillinger 1995, p. 470).

NAPIER'S ANALOGIES are

$$\frac{\sin\left[\frac{1}{2}(A-B)\right]}{\sin\left[\frac{1}{2}(A+B)\right]} = \frac{\tan\left[\frac{1}{2}(a-b)\right]}{\tan\left(\frac{1}{2}c\right)} \tag{46}$$

$$\frac{\cos\left[\frac{1}{2}(A-B)\right]}{\cos\left[\frac{1}{2}(A+B)\right]} = \frac{\tan\left[\frac{1}{2}(a+b)\right]}{\tan\left(\frac{1}{2}c\right)} \tag{47}$$

$$\frac{\sin\left[\frac{1}{2}(a-b)\right]}{\sin\left[\frac{1}{2}(a+b)\right]} = \frac{\tan\left[\frac{1}{2}(A-B)\right]}{\cot\left(\frac{1}{2}C\right)} \tag{48}$$

$$\frac{\cos\left[\frac{1}{2}(a-b)\right]}{\cos\left[\frac{1}{2}(a+b)\right]} = \frac{\tan\left[\frac{1}{2}(A+B)\right]}{\cot\left(\frac{1}{2}C\right)} \tag{49}$$

(Beyer 1987; Gellert *et al.* 1989, p. 266; Zwillinger 1995, p. 471).

SphericalHarmonicY

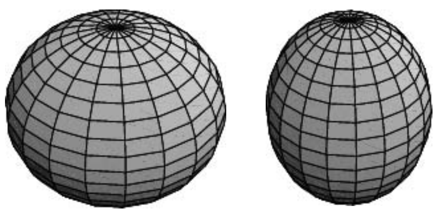
SPHERICAL HARMONIC

Sphericon

The solid formed from a BICONE with opening angle of 90°. Slice the solid by a plane containing the rotational axes. The resulting CROSS SECTION is a SQUARE. Now rotate the two pieces by 90° and reconnect them.

The above net shows another way the sphericon can be constructed. In this figure $\theta = \pi\sqrt{2}/2$ radians ≈

127.28°. This solid was discovered by C. J. Roberts, and is not as widely known as it should be!



A sphericon has a single continuous face. A sphericon rolls by wobbling from one face to another, resulting in straight-line motion. In addition, one sphericon can roll around another.

See also BICONE, CONE, CONE NET, SPHERE

References

Stewart, I. "Cone with a Twist." *Sci. Amer.* **281**, 116–17, Oct. 1999.

Spheroid

A spheroid is an ELLIPSOID

$$\frac{r^2\cos^2\theta\sin^2\phi}{a^2}+\frac{r^2\sin^2\theta\sin^2\phi}{b^2}+\frac{r^2\cos^2\phi}{c^2}=1 \quad (1)$$

with two SEMIMAJOR AXES equal. Orient the ELLIPSE so that the a and b axes are equal, then

$$\frac{r^2\cos^2\theta\sin^2\phi}{a^2}+\frac{r^2\sin^2\theta\sin^2\phi}{a^2}+\frac{r^2\cos^2\phi}{c^2}=1 \quad (2)$$

$$\frac{r^2\sin^2\phi}{a^2}+\frac{r^2\cos^2\phi}{c^2}=1. \quad (3)$$

where a is the equatorial RADIUS and c is the polar RADIUS. The PARAMETRIC EQUATIONS therefore become

$$x=a\cos\theta\sin\phi \quad (4)$$

$$y=a\sin\theta\sin\phi \quad (5)$$

$$z=c\cos\phi \quad (6)$$

for $\theta\in[0,\ 2\pi)$ and $\phi\in[0,\ \pi]$.

Here ϕ is the colatitude, so take $\delta\equiv\pi/2-\phi$ to express in terms of latitude.

$$\frac{r^2\cos^2\delta}{a^2}+\frac{r^2\sin^2\delta}{c^2}=1. \quad (7)$$

Rewriting $\cos^2\delta=1-\sin^2\delta$ gives

$$\frac{r^2}{a^2}+r^2\sin^2\delta\left(\frac{1}{c^2}-\frac{1}{a^2}\right)=1 \quad (8)$$

$$r^2\left(1+a^2\sin^2\delta\,\frac{a^2-c^2}{c^2a^2}\right)=r^2\left(1+\sin^2\delta\,\frac{a^2-c^2}{c^2}\right)=a^2. \quad (9)$$

so

$$r=a\left(1+\sin^2\delta\,\frac{a^2-c^2}{c^2}\right)^{-1/2}. \quad (10)$$

If $a>c$, the spheroid is OBLATE. If $a<c$, the spheroid is PROLATE. If $a=c$, the spheroid degenerates to a SPHERE.

Spheroidal Wave Function

Whittaker and Watson (1990, p. 403) define the internal and external spheroidal wavefunctions as

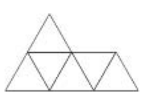
$$S_{mn}^{(1)}=2\pi\,\frac{(n-m)!}{(n+m)!}\,P_n^m(ir)P_n^m(\cos\theta)_{\sin}^{\cos}(m\phi)$$

$$S_{mn}^{(2)}=2\pi\,\frac{(n-m)!}{(n+m)!}\,Q_n^m(ir)Q_n^m(\cos\theta)_{\sin}^{\cos}(m\phi),$$

where $P_l^m(x)$ is a LEGENDRE POLYNOMIAL and $Q_l^m(x)$ is a LEGENDRE FUNCTION OF THE SECOND KIND.

Stratton (1935), Chu and Stratton (1941), and Rhodes (1970) define the spheroidal functions as those solutions of the differential equation

$$(1-\eta^2)\psi''_{\alpha n}(c,\ \eta)-2(\alpha+1)\eta\psi'_{\alpha n}(c,\ \eta)$$
$$+(b_{\alpha n}-c^2\eta^2)\psi_{\alpha n}(c,\ \eta)=0$$



which remain finite at the singular points $\eta=\pm 1$. The condition of finiteness restricts the admissible values of the parameter $b_{\alpha n}(c)$ to a discrete set of eigenvalues indexed by $n=0, 1, 2, \ldots$ (Rhodes 1970).

Spider and Fly Problem

In a rectangular room (a cuboid) with dimensions $30' \times 12' \times 12'$, a spider is located in the middle of one $12' \times 12'$ wall one foot away from the ceiling. A fly is in the middle of the opposite wall one foot away from the floor. If the fly remains stationary, what is the shortest distance the spider must crawl to capture the fly? The answer, $40'$, can be obtained by "flattening" the walls as illustrated above. The puzzle was originally posed in an English newspaper by Dudeney in 1903 (Gardner 1958).

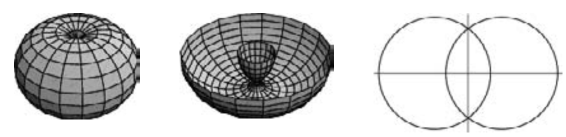
Spindle

Lemon, Spindle Cyclide



Spindle Cyclide

The inversion of a spindle torus. If the inversion center lies on the torus, then the spindle cyclide degenerates to a parabolic spindle cyclide.

See also Cyclide, Horn Cyclide, Parabolic Cyclide, Ring Cyclide, Spindle Torus, Torus

Spindle Torus

One of the three standard tori given by the parametric equations

$$x = (c + a \cos v)\cos u$$

$$y = (c + a \cos v)\sin u$$

$$z = a \sin v$$

with $c < a$. The exterior surface is called an apple and the interior surface a lemon. The above left figure shows a spindle torus, the middle a cutaway, and the right figure shows a cross section of the spindle torus through the xz-plane.

See also Apple, Cyclide, Horn Torus, Lemon, Parabolic Spindle Cyclide, Ring Torus, Spindle Cyclide, Standard Tori, Torus

Spindle-Shaped Ellipsoid

PROLATE SPHEROID

Spinode

A function $f(x)$ has a spinode (also called a horizontal cusp) at a point x_0 if $f(x)$ is CONTINUOUS at x_0 and

$$\lim_{x\to x_0} f'(x) = \infty$$

from one side while

$$\lim_{x\to x_0} f'(x) = -\infty$$

from the other side, so the curve is CONTINUOUS but the DERIVATIVE is not.

See also ACNODE, CRUNODE, CUSP, TACNODE

Spinor

A two-component COMPLEX COLUMN VECTOR. Spinors are used in physics to represent particles with half-integral spin (i.e., fermions).

See also LIE DERIVATIVE (SPINOR), MINKOWSKI SPACE, SPINOR FIELD, TWISTOR

Spira Mirabilis

LOGARITHMIC SPIRAL

Spiral

In general, a spiral is a curve with $\tau(s)/\kappa(s)$ equal to a constant for all s, where τ is the TORSION and κ is the CURVATURE.

See also ARCHIMEDES' SPIRAL, CIRCLE INVOLUTE, CONICAL SPIRAL, CORNU SPIRAL, COTES' SPIRAL, DAISY, EPISPIRAL, FERMAT'S SPIRAL, HELIX, HYPERBOLIC SPIRAL, LOGARITHMIC SPIRAL, MICE PROBLEM, NIELSEN'S SPIRAL, PHYLLOTAXIS, POINSOT'S SPIRALS, POLYGONAL SPIRAL, SPHERICAL SPIRAL

Spiral Point

A FIXED POINT for which the EIGENVALUES are COMPLEX CONJUGATES.

See also STABLE SPIRAL POINT, UNSTABLE SPIRAL POINT

References

Tabor, M. "Classification of Fixed Points." §1.4.b in *Chaos and Integrability in Nonlinear Dynamics: An Introduction.* New York: Wiley, pp. 22–5, 1989.

Spiral Similarity

The combination of a CENTRAL DILATION and a ROTATION about the *same* center. However, the combination of a central dilation and a rotation whose centers are *distinct* is also a spiral symmetry. In fact, any two DIRECTLY SIMILAR figures are related either by a TRANSLATION or by a spiral symmetry (Coxeter and Greitzer 1967, p. 97).

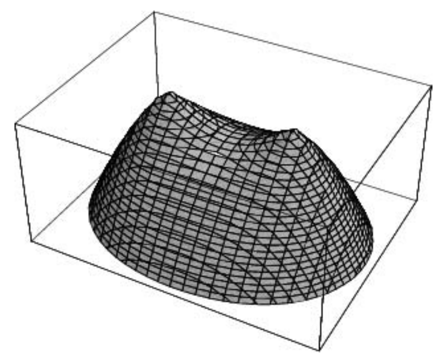
Spiric Section

The equation of the curve of intersection of a TORUS with a plane perpendicular to both the midplane of the torus and to the plane $x=0$. (The general intersection of a TORUS with a plane is called a TORIC SECTION). Let the tube of a torus have radius a, let its midplane lie in the $z=0$ plane, and let the center of the tube lie at a distance c from the origin. Now cut the torus with the plane $y=r$. The equation of the TORUS with $y=r$ gives the equation



$$\left(c-\sqrt{x^2+r^2}\right)^2+z^2=a^2 \quad (1)$$

$$c^2-a^2+x^2+z^2=2c\sqrt{x^2+r^2} \quad (2)$$

$$\left(r^2-a^2+c^2+x^2+z^2\right)^2=4c^2\left(x^2+r^2\right). \quad (3)$$

The above plots show a series of spiric sections for the RING TORUS, HORN TORUS, and SPINDLE TORUS, respectively. When $r=0$, the curve consists of two CIRCLES of RADIUS a whose centers are at $(c,\ 0)$ and $(-c,\ 0)$. If $r=c+a$, the curve consists of one point (the origin), while if $r>c+a$, no point lies on the curve.

The spiric extensions are an extension of the CONIC SECTIONS constructed by Menaechmus around 150 BC by cutting a CONE by a PLANE, and were first considered around 50 AD by the Greek mathematician Perseus (MacTutor).

If $r=a$, then (3) simplifies to

$$\left(x^2+z^2+c^2\right)^2-4c^2x^2=4c^2a^2, \quad (4)$$

which is the equation of CASSINI OVALS. CASSINI OVALS are therefore SPIRIC SECTIONS. Furthermore, the surface having these curves as CROSS SECTIONS is the CASSINI SURFACE illustrated above, with the modification that the vertical component is squared instead of to the fourth power (Gosper).

See also TORIC SECTION, TORUS

Spirograph

A HYPOTROCHOID generated by a fixed point on a CIRCLE rolling inside a fixed CIRCLE. It has parametric equations,

$$x=(R+r)\cos\theta-(r+\rho)\cos\left(\frac{R+r}{r}\theta\right) \quad (1)$$

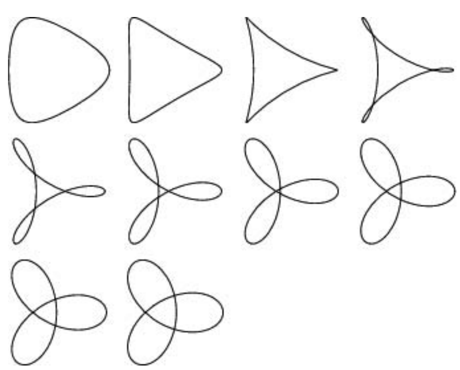
$$y=(R+r)\sin\theta-(r+\rho)\sin\left(\frac{R+r}{r}\theta\right), \quad (2)$$

where R is the radius of the fixed circle, r is the radius of the rotating circle, and ρ is the offset of the edge of the rotating circle. The figure closes only if R, r, and ρ are RATIONAL. The equations can also be written

$$x = x_0[m \cos t + a \cos(nt)] - y_0[m \sin t - a \sin(nt)] \quad (3)$$

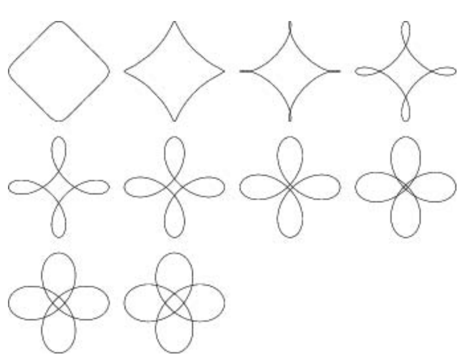
$$y = y_0[m \cos t + a \cos(nt)] + x_0[m \sin t - a \sin(nt)]. \quad (4)$$

where the outer wheel has radius 1, the inner wheel a radius p/q, the pen is placed a units from the center, the beginning is at θ radians above the x-AXIS, and



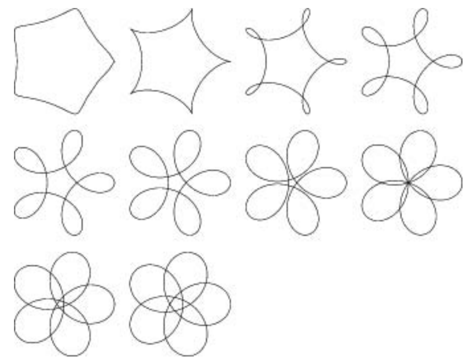
$$m \equiv \frac{q-p}{q} \quad (5)$$

$$n \equiv \frac{q-p}{p} \quad (6)$$

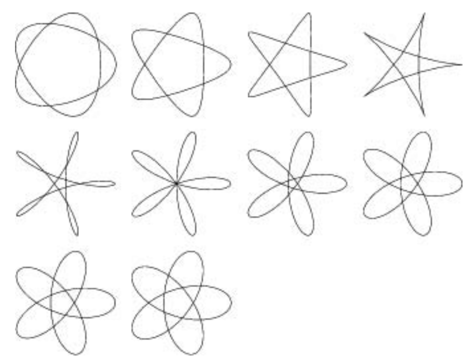


$$x_0 \equiv \cos\theta \quad (7)$$

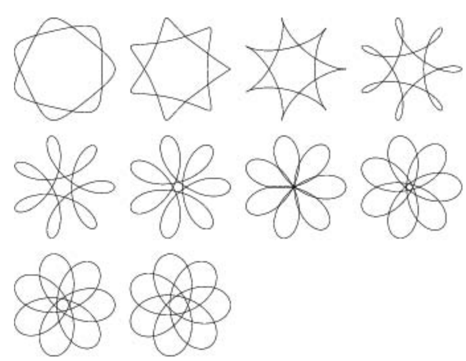
$$y_0 \equiv \sin\theta. \quad (8)$$



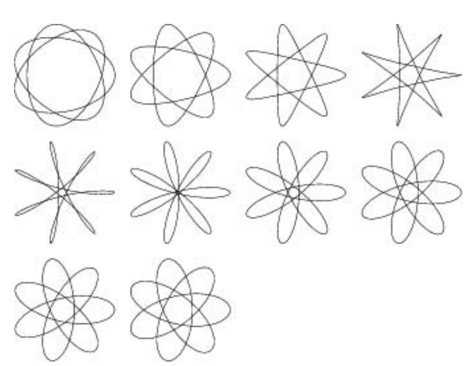
The following curves are for $a = i/10$, with $i = 1, 2, ..., 10$, and $\theta = 0$.



$(p, q) = (1, 3)$

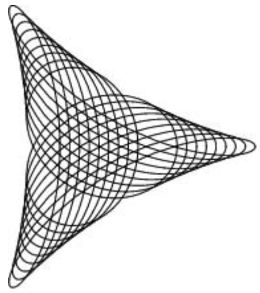


$(p, q) = (1, 4)$



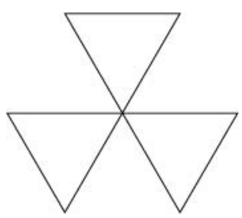
$(p, q) = (1, 5)$

$(p, q) = (2, 5)$

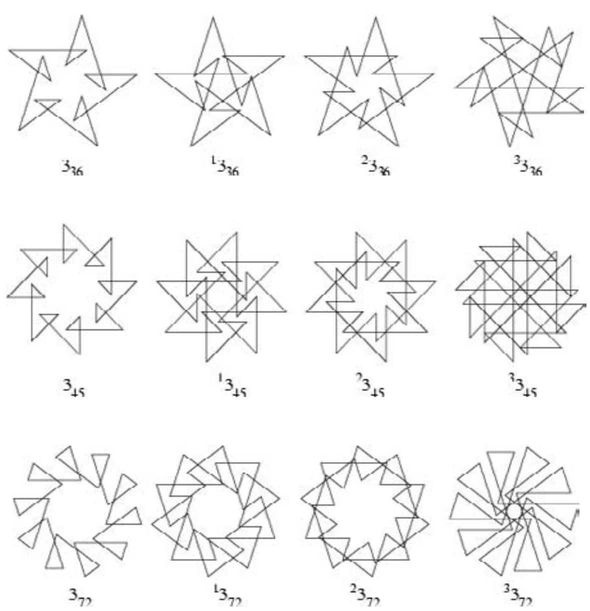


$(p, q) = (2, 7)$

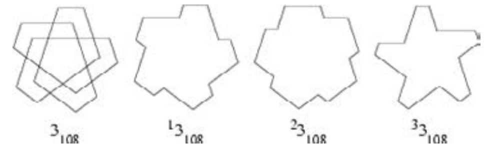
$$(p,\ q) = (3,\ 7)$$



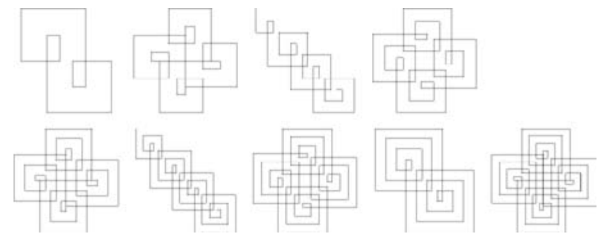
Additional attractive designs such as the following can also be made by superposing individual spirographs.



See also EPITROCHOID, HARMONOGRAPH, HYPOTROCHOID, MAURER ROSE, SPIROLATERAL



Spirolateral



A figure formed by taking a series of steps of length 1, 2, ..., n, with an angle θ turn after each step. The symbol for a spirolateral is ${}^{a_1, \ldots, a_k}n_\theta$, where the a_is indicate that turns are in the $-\theta$ direction for these steps.

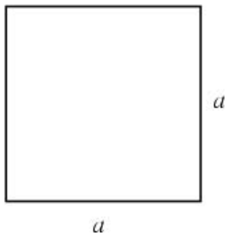
Spun Knot
A 3-D knot spun about a plane in 4-D. Unlike suspended knots, spun knots are smoothly embedded at the poles.



See also Suspended Knot, Twist-Spun Knot

Spur
Trace (Matrix)

Sqrt
Square Root

Squarable
An object which can be constructed by squaring is called squarable.

Square

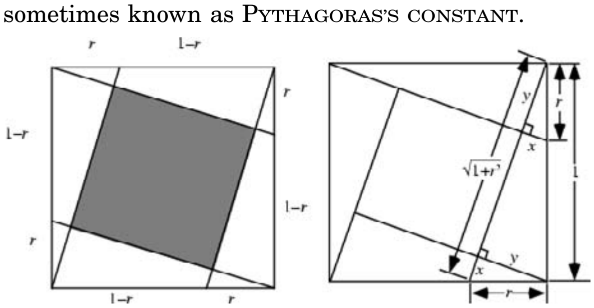
The term square is sometimes used to mean SQUARE NUMBER. When used in reference to a geometric figure, however, it means a convex QUADRILATERAL with four equal sides at RIGHT ANGLES to each other, illustrated above. When used as a symbol, $\square ABCD$ denotes a square with given vertices, while $G_1 \square G_2$ is sometimes used to denote a GRAPH PRODUCT (Clark and Suen 2000).

The PERIMETER of a square with side length a is

$$L = 4a \tag{1}$$

and the AREA is

$$A = a^2. \tag{2}$$



The INRADIUS r, CIRCUMRADIUS R, and AREA A can be computed directly from the formulas for a general REGULAR POLYGON with side length a and $n = 4$ sides,

$$r = \tfrac{1}{2} a \cot\left(\frac{\pi}{4}\right) = \tfrac{1}{2} a \tag{3}$$

$$R = \tfrac{1}{2} a \csc\left(\frac{\pi}{4}\right) = \tfrac{1}{2}\sqrt{2} a \tag{4}$$

$$A = \tfrac{1}{4} n a^2 \cot\left(\frac{\pi}{4}\right) = a^2, \tag{5}$$

The length of the DIAGONAL of the UNIT SQUARE is $\sqrt{2}$, sometimes known as PYTHAGORAS'S CONSTANT.

The AREA of a square constructed inside a UNIT SQUARE as shown in the above diagram can be found as follows. Label x and y as shown, then

$$x^2 + y^2 = r^2 \tag{6}$$

$$\left(\sqrt{1+r^2} - x\right)^2 + y^2 = 1. \tag{7}$$

Plugging (6) into (7) gives

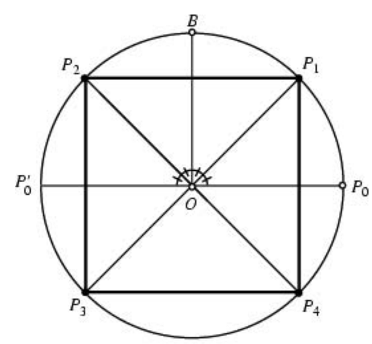
$$\left(\sqrt{1+r^2} - x\right)^2 + \left(r^2 - x^2\right) = 1. \tag{8}$$

Expanding

$$x^2 - 2x\sqrt{1+r^2} + 1 + r^2 + r^2 - x^2 = 1 \tag{9}$$

and solving for x gives

$$x = \frac{r^2}{\sqrt{1+r^2}}. \tag{10}$$



Plugging in for y yields

$$y = \sqrt{r^2 - x^2} = \frac{r}{\sqrt{1+r^2}}. \tag{11}$$

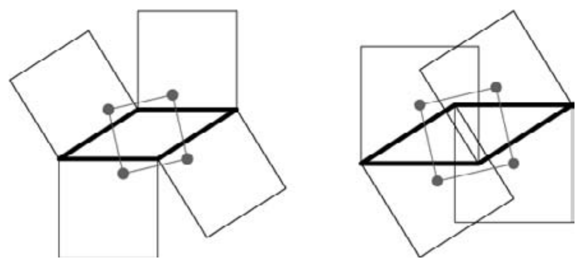
The area of the shaded square is then

$$A = \left(\sqrt{1+r^2} - x - y\right)^2 = \frac{(1-r)^2}{1+r^2} \tag{12}$$

(Detemple and Harold 1996).

square construction

The STRAIGHTEDGE and COMPASS construction of the square is simple. Draw the line $P'_O O P_0$ and construct a circle having OP_0 as a radius. Then construct the perpendicular OB through O. Bisect $P_0 OB$ and $P'_0 OB$ to locate P_1 and P_2, where P'_0 is opposite P_0. Similarly, construct P_3 and P_4 on the other SEMICIRCLE. Connecting $P_1 P_2 P_3 P_4$ then gives a square.



An infinity of points in the interior of a square are known whose distances from three of the corners of a square are RATIONAL NUMBERS. Calling the distances a, b, and c where s is the side length of the square, these solutions satisfy

$$\left(s^2 + b^2 - a^2\right)^2 + \left(s^2 + b^2 - c^2\right)^2 = (2bs)^2 \tag{13}$$

(Guy 1994). In this problem, one of a, b, c, and s is DIVISIBLE by 3, one by 4, and one by 5. It is not known if there are points having distances from *all four* corners RATIONAL, but such a solution requires the additional condition

$$a^2 + c^2 = b^2 + d^2. \tag{14}$$

In this problem, s is DIVISIBLE by 4 and a, b, c, and d are ODD. If s is not DIVISIBLE by 3 (5), then two of a, b, c, and d are DIVISIBLE by 3 (5) (Guy 1994).

The centers of four squares erected either internally or externally on the sides of a PARALLELOGRAMS are the vertices of a square (Yaglom 1962, pp. 96–7; Coxeter and Greitzer 1967, p. 84).

Square Antiprism

The ANTIPRISM with square bases.

See also ANTIPRISM, SQUARE PRISM

Square Bracket

One of the symbols [and] used in many different contexts in mathematics.

1. Square brackets are occasionally used in especially complex expressions in place of (or in addition to) PARENTHESES, especially as a group symbol outside an inner set of parentheses, e.g., $[3+4\times(5+6)]/7$.
2. Large brackets around an array of numbers, e.g., $\left[\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right]$ indicate a MATRIX. (The symbol $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ is also commonly used.)
3. A square bracket at one end of an INTERVAL indicates that the INTERVAL is closed at that end, that is, it includes the number at that end.
4. Brackets may be used to denote the LEAST COMMON MULTIPLE, e.g., $[10,\ 6]\equiv \mathrm{LCM}(10,\ 6)=30$.
5. Some authors (although this work does *not*) use $[x]$ to denote the FLOOR FUNCTION $\lfloor x \rfloor$.

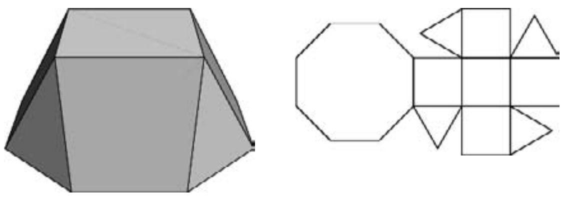
Square Bracket Polynomial

A POLYNOMIAL which is not necessarily an invariant of a LINK. It is related to the DICHROIC POLYNOMIAL. It is defined by the SKEIN RELATIONSHIP

$$B_{L_+} = q^{-1/2} v B_{L_0} + B_{L_\infty}, \tag{1}$$

and satisfies

$$B_{\text{unknot}} = q^{1/2} \tag{2}$$



and

$$B_{L \cup \text{unknot}} = q^{1/2} B_L. \tag{3}$$

Square Cupola

JOHNSON SOLID J_4. The bottom eight VERTICES are

$$\left(\pm\tfrac{1}{2}\left(1+\sqrt{2}\right),\ \pm\tfrac{1}{2},\ 0\right),\ \left(\pm\tfrac{1}{2},\ \pm\tfrac{1}{2}\left(1+\sqrt{2}\right),\ 0\right),$$

and the top four VERTICES are

$$\left(\pm\frac{1}{\sqrt{2}},\ 0,\ \frac{1}{\sqrt{2}}\right),\ \left(0,\ \pm\frac{1}{\sqrt{2}},\ \frac{1}{\sqrt{2}}\right).$$

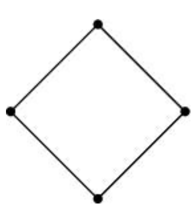
Square Curve

SIERPINSKI CURVE

Square Division by Lines

The average number of regions $N(n)$ into which n lines divide a SQUARE is

$$N(n)=\tfrac{1}{16}n(n-1)\pi+n+1$$



(Santaló 1976).

Square Inscribing

As shown by Schnirelman (1944), a SQUARE can be INSCRIBED in any closed convex curve, although it is not known if this holds true for every JORDAN CURVE (Steinhaus 1983, p. 104). However, a SQUARE can be CIRCUMSCRIBED about *any* JORDAN CURVE (Steinhaus 1999, p. 104).

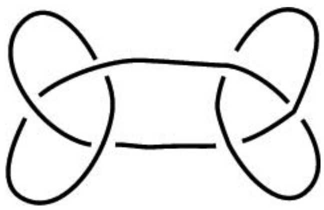
Square Integrable

A function $f(x)$ is said to be square integrable if

$$\int_{-\infty}^{\infty}|f(x)|^2\,dx$$



is finite.

Square Knot

A composite KNOT of six crossings consisting of a KNOT SUM of a TREFOIL KNOT and its MIRROR IMAGE. The GRANNY KNOT has the same ALEXANDER POLYNOMIAL $(x^2 - x + 1)^2$ as the square knot. The square knot is also called the REEF KNOT.

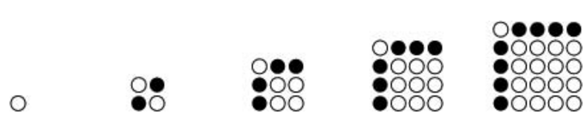
Square Matrix

A MATRIX for which horizontal and vertical dimensions are the same (i.e., an $n \times n$ MATRIX). A matrix can be tested to see if it is square using `SquareMatrixQ[m]` in the *Mathematica* add-on package `LinearAlgebra'MatrixMultiplication'` (which can be loaded with the command `<<LinearAlgebra'`).



See also MATRIX, RECTANGULAR MATRIX

Square Number

A FIGURATE NUMBER OF THE FORM $S_n = n^2$, where n is an INTEGER. A square number is also called a PERFECT SQUARE. The first few square numbers are 1, 4, 9, 16, 25, 36, 49, ... (Sloane's A000290). The GENERATING FUNCTION giving the square numbers is

$$\frac{x(x+1)}{(1-x)^3} = x + 4x^2 + 9x^3 + 16x^4 + \ldots. \quad (1)$$

The $(n+1)$st square number S_{n+1} is given in terms of the nth square number S_n by

$$S_{n+1} = S_n + 2n + 1. \quad (2)$$

since

$$(n+1)^2 = n^2 + 2n + 1, \quad (3)$$

which is equivalent to adding a GNOMON to the previous square, as illustrated above.

The nth square number is equal to the sum of the $(n-1)$-st and nth TRIANGULAR NUMBERS,

$$S_n = \tfrac{1}{2}(n-1)n + \tfrac{1}{2}n(n+1) = n^2. \quad (4)$$

as can seen in the above diagram, in which the $(n-1)$-st triangular number is represented by the white triangles, the nth triangular number is represented by the black triangles, and the total number of triangles is the square number $S_n = n^2$ (R. Sobel).

As a part of the study of WARING'S PROBLEM, it is known that every positive integer is a sum of no more than 4 positive squares ($g(2) = 4$; LAGRANGE'S FOUR-SQUARE THEOREM), that every "sufficiently large" integer is a sum of no more than 4 positive squares ($G(2) = 4$), and that every integer is a sum of at most 3 signed squares ($eg(2) = 3$). Actually, the basis set for representing positive integers with positive squares is $\{1, 1, 4, 9, 16, 25, 36, 64, 81, 100, \ldots\}$, so 49 need never be used. Furthermore, since an infinite number of n require four squares to represent them, the least INTEGER $G(2)$ such that every POSITIVE INTEGER beyond a certain point requires $G(2)$ squares is given by $G(2) = 4$.

The number of representation of a number n by k squares, distinguishing signs and order, is denoted $r_k(n)$ and called the SUM OF SQUARES FUNCTION. The minimum number of squares needed to represent the numbers 1, 2, 3, ... are 1, 2, 3, 1, 2, 3, 4, 2, 1, 2, ... (Sloane's A002828), and the number of distinct ways to represent the numbers 1, 2, 3, ... in terms of squares are 1, 1, 1, 2, 2, 2, 2, 3, 4, 4, ... (Sloane's A001156). A brute-force algorithm for enumerating the square partitions of n is repeated application of the GREEDY ALGORITHM. However, this approach rapidly becomes impractical since the number of representations grows extremely rapidly with n, as shown in the following table.

n	Square Partitions
10	4
50	104

100	1116
150	6521
200	27482

The kth nonsquare number a_k is given by

$$a_n = n + \left\lfloor \tfrac{1}{2} + \sqrt{n} \right\rfloor, \tag{5}$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION, and the first few are 2, 3, 5, 6, 7, 8, 10, 11, ... (Sloane's A000037).

The only numbers which are simultaneously square and PYRAMIDAL (the CANNONBALL PROBLEM) are $P_1 = 1$ and $P_{24} = 4900$, corresponding to $S_1 = 1$ and $S_{70} = 4900$ (Dickson 1952, p. 25; Ball and Coxeter 1987, p. 59; Ogilvy 1988), as conjectured by Lucas (1875, 1876) and proved by Watson (1918). The CANNONBALL PROBLEM is equivalent to solving the DIOPHANTINE EQUATION

$$y^2 = \tfrac{1}{6} x(x+1)(2x+1) \tag{6}$$

(Guy 1994, p. 147).

The only numbers which are square and TETRAHEDRAL are $Te_1 = 1$, $Te_2 = 4$, and $Te_{48} = 19600$ (giving $S_1 = 1$, $S_2 = 4$, and $S_{140} = 19600$), as proved by Meyl (1878; cited in Dickson 1952, p. 25; Guy 1994, p. 147). In general, proving that only certain numbers are simultaneously figurate in two different ways is far from elementary.

To find the possible last digits for a square number, write $n = 10a + b$ for the number written in decimal NOTATION as ab_{10} (a, $b = 0, 1, ..., 9$). Then

$$n^2 = 100a^2 + 20ab + b^2. \tag{7}$$

so the last digit of n^2 is the same as the last digit of b^2. The following table gives the last digit of b^2 for $b = 0, 1, ..., 9$ (where numbers with more that one digit have only their last digit indicated, i.e., 16 becomes _6). As can be seen, the last digit can be only 0, 1, 4, 5, 6, or 9.

0	1	2	3	4	5	6	7	8	9
0	1	4	9	_6	_5	_6	_9	_4	_1

We can similarly examine the allowable last two digits by writing abc_{10} as

$$n = 100a + 10b + c, \tag{8}$$

so

$$n^2 = (100a + 10b + c)^2$$

$$= 10^4a^2 + 2(1000ab + 100ac + 10bc) + 100b^2 + c^2$$

$$= (10^4a^2 + 2000ab + 100ac + 100b^2) + 20bc + c^2$$

$$= 100(100a^2 + 20ab + ac + b^2) + (20bc + c^2) \tag{9}$$

so the last two digits must have the last two digits of $20bc + c^2$. Furthermore, the last two digits can be obtained by considering only $b = 0, 1, 2, 3,$ and 4, since

$$20(b+5)c + c^2 = 100c + \left(20bc + c^2\right) \tag{10}$$

has the same last two digits as $20bc + c^2$ (with the one additional possibility that $c = 0$ in which case the last two digits are 00). The following table (with the addition of 00) therefore exhausts all possible last two digits.

	c								
b	1	2	3	4	5	6	7	8	9
0	01	04	09	16	25	36	49	64	81
1	_21	_44	_69	_96	_25	_56	_89	_24	_61
2	_41	_84	_29	_76	_25	_76	_29	_84	_41
3	_61	_24	_89	_56	_25	_96	_69	_44	_21
4	_81	_64	_49	_36	_25	_16	_09	_04	_01

The only 22 possibilities are therefore 00, 01, 04, 09, 16, 21, 24, 25, 29, 36, 41, 44, 49, 56, 61, 64, 69, 76, 81, 84, 89, and 96, which can be summarized succinctly as 00, e1, e4, 25, o6, and e9, where e stands for an EVEN NUMBER and o for an ODD NUMBER. Additionally, a NECESSARY (but not SUFFICIENT) condition for a number to be square is that its DIGITAL ROOT be 1, 4, 7, or 9. The digital roots of the first few squares are 1, 4, 9, 7, 7, 9, 4, 1, 9, 1, 4, 9, 7, ... (Sloane's A056992), while the list of number having digital roots 1, 4, 7, or 9 is 1, 4, 7, 9, 10, 13, 16, 18, 19, 22, 25, ... (Sloane's A056991).

The following table gives the possible residues mod n for square numbers for $n = 1$ to 20. The quantity $s(n)$ gives the number of distinct residues for a given n.

n	$s(n)$	$x^2 (\bmod n)$
2	2	0, 1
3	2	0, 1
4	2	0, 1
5	3	0, 1, 4
6	4	0, 1, 3, 4

7	4	0, 1, 2, 4
8	3	0, 1, 4
9	4	0, 1, 4, 7
10	6	0, 1, 4, 5, 6, 9
11	6	0, 1, 3, 4, 5, 9
12	4	0, 1, 4, 9
13	7	0, 1, 3, 4, 9, 10, 12
14	8	0, 1, 2, 4, 7, 8, 9, 11
15	6	0, 1, 4, 6, 9, 10
16	4	0, 1, 4, 9
17	9	0, 1, 2, 4, 8, 9, 13, 15, 16
18	8	0, 1, 4, 7, 9, 10, 13, 16
19	10	0, 1, 4, 5, 6, 7, 9, 11, 16, 17
20	6	0, 1, 4, 5, 9, 16

In general, the ODD squares are congruent to 1 (mod 8) (Conway and Guy 1996). Stangl (1996) gives an explicit formula by which the number of squares $s(n)$ in $\mathbb{Z}_n$ (i.e., mod n) can be calculated. Let p be an *ODD* PRIME. Then $s(n)$ is the MULTIPLICATIVE FUNCTION given by

$$s(2) = 2 \tag{11}$$

$$s(p) = \tfrac{1}{2}(p+1) \quad (p \neq 2) \tag{12}$$

$$s(p^2) = \tfrac{1}{2}(p^2 - p + 2) \quad (p \neq 2) \tag{13}$$

$$s(2^n) = \begin{cases} \frac{1}{3}(2^{n-1}+4) & \text{for } n \text{ even} \\ \frac{1}{3}(2^{n-1}+5) & \text{for } n \text{ odd} \end{cases} \tag{14}$$

$$s(p^n) = \begin{cases} \dfrac{p^{n+1}+p+2}{2(p+1)} & \text{for } n \geq 3 \text{ even} \\ \dfrac{p^{n+1}+2p+1}{2(p+1)} & \text{for } n \geq 3 \text{ odd.} \end{cases} \tag{15}$$

$s(n)$ is related to the number $q(n)$ of QUADRATIC RESIDUES in $\mathbb{Z}_n$ by

$$q(p^n) = s(p^n) - s(p^{n-2}) \tag{16}$$

for $n \geq 3$ (Stangl 1996).

For a perfect square n, $(n/p) = 0$ or 1 for all ODD PRIMES $p < n$ where (n/p) is the LEGENDRE SYMBOL. A number n which is not a perfect square but which satisfies this relationship is called a PSEUDOSQUARE.

In a Ramanujan conference talk, W. Gosper conjectured that every sum of four distinct odd squares is the sum of four distinct even squares. This conjecture was proved by M. Hirschhorn using the identity

$$\begin{aligned}(4a+1)^2 + (4b+1)^2 + (4c+1)^2 + (4d+1)^2 \\ = 4[(a+b+c+d+1)^2 + (a-b-c+d)^2 \\ +(a-b+c-d)^2 + (a+b-c-d)^2],\end{aligned} \tag{17}$$

where a, b, c, and d are positive or negative integers. Hirschhorn also showed that every sum of four distinct oddly even squares is the sum of four distinct odd squares.

A PRIME NUMBER p can be written as the sum of two squares IFF $p+1$ is not divisible by 4 the (FERMAT $4N+1$ THEOREM). An arbitrary positive number n is expressible as the sum of two squares IFF, given its PRIME FACTORIZATION

$$n = p_1^{a_1} p_2^{a_2} p_3^{a_3} \cdots p_k^{a_k}, \tag{18}$$

none of $p_i^{a_i} + 1$ is divisible by 4 (Conway and Guy 1996, p. 147). This is equivalent the requirement that all the odd factors of the SQUAREFREE PART n' of n are equal to 1 (mod 4) (Hardy and Wright 1979, Finch). The first few numbers which can be expressed as the sum of two squares are 1, 2, 4, 5, 8, 9, 10, 13, 16, 17, 18, 20, 25, 26, ... (Sloane's A001481). Letting $\delta(n)$ be the fraction of numbers $\leq n$ which are expressible as the sum of two squares,

$$\lim_{n\to\infty} \delta(n) = 0, \tag{19}$$

and

$$\lim_{n\to\infty} \delta(n)\sqrt{\ln n} = K, \tag{20}$$

where K is the LANDAU-RAMANUJAN CONSTANT.

Numbers expressible as the sum of three squares are those not OF THE FORM $4^k(8l+7)$ for $k,\ l \geq 0$ (Nagell 1951, p. 194; Wells 1986, pp. 48 and 56; Hardy 1999, p. 12).

The following table gives the first few numbers which *require* $N = 1$, 2, 3, and 4 squares to represent them as a sum (Wells 1986, p. 70).

N	Sloane	Numbers
1	Sloane's A000290	1, 4, 9, 16, 25, 36, 49, 64, 81, ...
2	Sloane's A000415	2, 5, 8, 10, 13, 17, 18, 20, 26, 29, ...
3	Sloane's A000419	3, 6, 11, 12, 14, 19, 21, 22, 24, 27, ...
4	Sloane's A004215	7, 15, 23, 28, 31, 39, 47, 55, 60, 63, ...

The FERMAT $4N+1$ THEOREM guarantees that every PRIME OF THE FORM $4n+1$ is a sum of two SQUARE NUMBERS in only one way.

There are only 31 numbers which cannot be expressed as the sum of *distinct* squares: 2, 3, 6, 7, 8, 11, 12, 15, 18, 19, 22, 23, 24, 27, 28, 31, 32, 33, 43, 44, 47, 48, 60, 67, 72, 76, 92, 96, 108, 112, 128 (Sloane's A001422; Guy 1994; Savin 2000). The following numbers cannot be represented using fewer than five distinct squares: 55, 88, 103, 132, 172, 176, 192, 240, 268, 288, 304, 368, 384, 432, 448, 496, 512, and 752, together with all numbers obtained by multiplying these numbers by a power of 4. This gives all known such numbers less than 10^5 (Savin 2000). All numbers > 188 can be expressed as the sum of at most five distinct squares, and only

$$124 = 1 + 4 + 9 + 25 + 36 + 49 \tag{21}$$

and

$$188 = 1 + 4 + 9 + 25 + 49 + 100 \tag{22}$$

require six distinct squares (Bohman *et al.* 1979; Guy 1994, p. 136; Savin 2000). In fact, 188 can also be represented using seven distinct squares:

$$188 = 1 + 4 + 9 + 25 + 36 + 49 + 64. \tag{23}$$

The following table gives the numbers which can be represented in W different ways as a sum of S squares. For example,

$$50 = 1^2 + 7^2 = 5^2 + 5^2 \tag{24}$$

can be represented in two ways ($W = 2$) by two squares ($S = 2$).

S	W	Sloane	Numbers
1	1	Sloane's A000290	1, 4, 9, 16, 25, 36, 49, 64, 81, 100, 121, ...
2	1	Sloane's A025284	2, 5, 8, 10, 13, 17, 18, 20, 25, 26, 29, 32, ...
2	2	Sloane's A025285	50, 65, 85, 125, 130, 145, 170, 185, 200, ...
3	1	Sloane's A025321	3, 6, 9, 11, 12, 14, 17, 18, 19, 21, 22, 24, ...
3	2	Sloane's A025322	27, 33, 38, 41, 51, 57, 59, 62, 69, 74, 75, ...
3	3	Sloane's A025323	54, 66, 81, 86, 89, 99, 101, 110, 114, 126, ...
3	4	Sloane's A025324	129, 134, 146, 153, 161, 171, 189, 198, ...
4	1	Sloane's A025357	4, 7, 10, 12, 13, 15, 16, 18, 19, 20, 21, 22, ...
4	2	Sloane's A025358	31, 34, 36, 37, 39, 43, 45, 47, 49, 50, 54, ...
4	3	Sloane's A025359	28, 42, 55, 60, 66, 67, 73, 75, 78, 85, 95, 99, ...
4	4	Sloane's A025360	52, 58, 63, 70, 76, 84, 87, 91, 93, 97, 98, 103, ...

The least numbers which are the sum of two squares in exactly n different ways for $n = 1, 2, ...$ are given by 2, 50, 325, 1105, 8125, 5525, 105625, 27625, 71825, 138125, 5281250, ... (Sloane's A016032; Beiler 1966, pp. 140–41; Culbertson; Hardy and Wright 1979; Rivera).

The product of four distinct NONZERO INTEGERS in ARITHMETIC PROGRESSION is square only for $(-3, -1, 1, 3)$, giving $(-3)(-1)(1)(3) = 9$ (Le Lionnais 1983, p. 53). It is possible to have three squares in ARITHMETIC PROGRESSION, but not four (Dickson 1952, pp. 435–40). If these numbers are r^2, s^2, and t^2, there are POSITIVE INTEGERS p and q such that

$$r = |p^2 - 2pq - q^2| \tag{25}$$

$$s = p^2 + q^2 \tag{26}$$

$$t = p^2 + 2pq - q^2, \tag{27}$$

where $(p, q) = 1$ and one of r, s, or t is EVEN (Dickson 1952, pp. 437–38). Every three-term progression of squares can be associated with a PYTHAGOREAN TRIPLE (X, Y, Z)) by

$$X = \tfrac{1}{2}(r + t) \tag{28}$$

$$Y = \tfrac{1}{2}(t - r) \tag{29}$$

$$Z = s \tag{30}$$

(Robertson 1996).

CATALAN'S CONJECTURE states that 8 and 9 (2^3 and 3^2) are the only consecutive POWERS (excluding 0 and 1), i.e., the only solution to CATALAN'S DIOPHANTINE PROBLEM. This CONJECTURE has not yet been proved or refuted, although R. Tijdeman has proved that there can be only a finite number of exceptions should the CONJECTURE not hold. It is also known that 8 and 9 are the only consecutive CUBIC and square numbers (in either order).

The numbers that are not the difference of two squares are 2, 6, 10, 14, 18, ... (Wells 1986, p. 76).

A square number can be the concatenation of two squares, as in the case $16 = 4^2$ and $9 = 3^2$ giving $169 = 13^2$. The first few numbers which are neither square nor the sum of a square and a PRIME are 10, 34, 58, 85, 91, 130, 214, ... (Sloane's A020495).

It is conjectured that, other than 10^{2n}, 4×10^{2n} and 9×10^{2n}, there are only a FINITE number of squares n^2 having exactly two distinct NONZERO DIGITS (Guy 1994, p. 262). The first few such n are 4, 5, 6, 7, 8, 9,

11, 12, 15, 21, ... (Sloane's A016070), corresponding to n^2 of 16, 25, 36, 49, 64, 81, 121, ... (Sloane's A018884).

The following table gives the first few numbers which, when squared, give numbers composed of only certain digits. The values of n such that n^2 contains exactly two different digits are given by 4, 5, 6, 7, 8, 9, 10, 11, 12, 15, 20, ... (Sloane's A016069), whose squares are 16, 25 36, 49, 64, ... (Sloane's A018885). The only known square number composed only of the digits 7, 8, and 9 is 9. Based on a discussion in `rec.puzzles`, Vardi (1991) considered numbers composed only of the square digits: 1, 4, and 9. It is conjectured that there are only finitely many, and the largest known is

$$6480702115891070212^2 = 41999499914914994414914994419149444 1 \quad (31)$$

found by G. Jacobson and D. Applegate (`rec.puzzles` FAQ).

BROWN NUMBERS are pairs (m, n) of INTEGERS satisfying the condition of BROCARD'S PROBLEM, i.e., such that

$$n!+1=m^2, \quad (32)$$

where $n!$ is a FACTORIAL. Only three such numbers are known: (5,4), (11,5), (71,7). Erdos conjectured that these are the only three such pairs.

Either $5x^2+4=y^2$ or $5x^2-4=y^2$ has a solution in POSITIVE INTEGERS IFF, for some n, $(x, y)=(F_n, L_n)$, where F_n is a FIBONACCI NUMBER and L_n is a LUCAS NUMBER (Honsberger 1985, pp. 114–18).

The smallest and largest square numbers containing the digits 1 to 9 are

$$11,826^2=139,854,276, \quad (33)$$

$$30,384^2=923,187,456. \quad (34)$$

The smallest and largest square numbers containing the digits 0 to 9 are

$$32,043^2=1,026,753,849, \quad (35)$$

$$99,066^2=9,814,072,356 \quad (36)$$

(Madachy 1979, p. 159). The smallest and largest square numbers containing the digits 1 to 9 twice each are

$$335,180,136^2=112,345,723,568,978,496 \quad (37)$$

$$999,390,432^2=998,781,235,573,146,624, \quad (38)$$

and the smallest and largest containing 1 to 9 three times are

$$10,546,200,195,312^2 = 111,222,338,559,598,866,946,777,344 \quad (39)$$

$$31,621,017,808,182^2 = 999,888,767,225,363,175,346,145,124$$

(Madachy 1979, p. 159).

Madachy (1979, p. 165) also considers number which are equal to the sum of the squares of their two "halves" such as

$$1233=12^2+33^2 \quad (40)$$

$$8833=88^2+33^2 \quad (41)$$

$$10100=10^2+100^2 \quad (42)$$

$$5882353=588^2+2353^2, \quad (43)$$

in addition to a number of others.

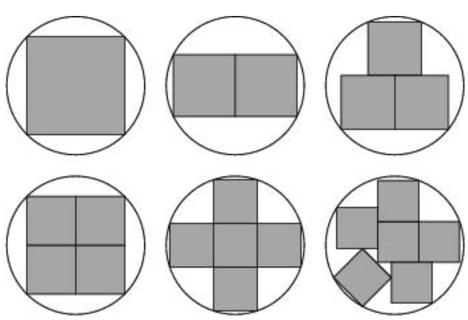
Square Packing

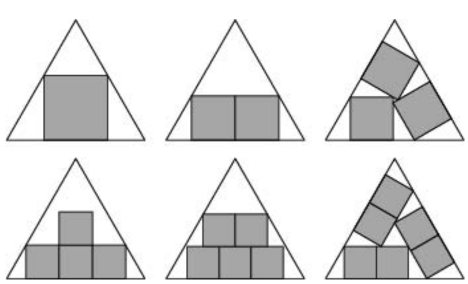
Find the minimum size SQUARE capable of bounding n equal SQUARES arranged in any configuration. The first few cases are illustrated above (Friedman). The only packings which have been proven optimal are 2, 3, 5, 6, 7, 8, 14, 15, 24, and 35, in addition to the trivial cases of the SQUARE NUMBERS (Friedman).

If $n = a^2 - a$ for some a, it is CONJECTURED that the size of the minimum bounding square is a for small n. The smallest n for which the CONJECTURE is known to be violated is $n = 272$ (with $a = 17$). The size is known to scale as k^b, where



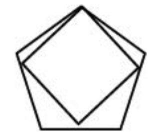
$$\tfrac{1}{2}\left(3-\sqrt{3}\right) < b < \tfrac{1}{2}.$$

The following table gives the smallest known side lengths for a square into which n unit squares can be packed.



n	exact	approx.	n	exact	approx.
1	1	1	14	4	4
2	2	2	15	4	4
3	2	2	16	4	4
4	2	2	17	$4+\frac{1}{2}\sqrt{2}$	4.707...
5	$2+\frac{1}{2}\sqrt{2}$	2.707...	18	$\frac{1}{2}(7+\sqrt{7})$	4.822...
6	3	3	19	$3+\frac{4}{3}\sqrt{2}$	4.885...
7	3	3	20	5	5
8	3	3	21	5	5
9	3	3	22	5	5
10	$3+\frac{1}{2}\sqrt{2}$	3.707...	23	5	5
11	s_{11}	3.877...	24	5	5
12	4	4	25	5	5
13	4	4	26		5.650...

Here, s_{11} is the larger of the two positive real roots of



$$s^4 - 10s^3 + 35s^2 - 46s + 9.$$

The best known packings of squares into a circle are illustrated above for the first few cases (Friedman).

The best known packings of squares into an equilateral triangle are illustrated above for the first few cases (Friedman).

The best packing of a SQUARE inside a PENTAGON, illustrated above, is 1.0673....

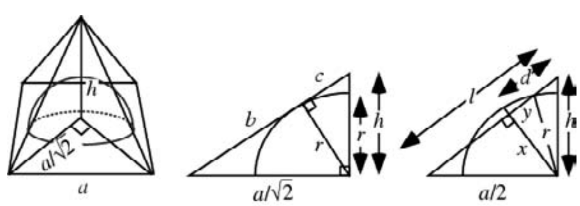
Square Prism

CUBE, CUBOID

Square Pyramid

A square pyramid is a PENTAHEDRON consisting of a PYRAMID with a SQUARE base. If the top of the pyramid is cut off by a PLANE, a square PYRAMIDAL FRUSTUM is obtained. If the four TRIANGLES of the square pyramid are EQUILATERAL, the square pyramid is the "regular" POLYHEDRON known as JOHNSON SOLID J_1 and, for side length a, has height

$$h = \tfrac{1}{2}\sqrt{2}a. \tag{1}$$



Using the equation for a general PYRAMID, the VOLUME of the "regular" is therefore

$$V = \tfrac{1}{3}hA_b = \tfrac{1}{6}\sqrt{2}a^3. \tag{2}$$

The SLANT HEIGHT of a square pyramid is a special case of the formula for a regular n-gonal PYRAMID with $n = 2$, given by

$$s = \sqrt{h^2 + \tfrac{1}{2}a^2}, \tag{3}$$

where h is the height and a is the length of a side of the base.

(a) (b) (c)

Consider a HEMISPHERE placed on the base of a square pyramid (having side lengths a and height h). Further, let the hemisphere be tangent to the four apex edges. Then what is the volume of the HEMISPHERE which is interior the pyramid (Cipra 1993)?

From Fig. (a), the CIRCUMRADIUS of the base is $a/\sqrt{2}$. Now find h in terms of r and a. Fig. (b) shows a CROSS SECTION cut by the plane through the pyramid's apex, one of the base's vertices, and the base center. This figure gives

$$b = \sqrt{\tfrac{1}{2}a^2 - r^2} \tag{4}$$

$$c = \sqrt{h^2 - r^2}, \tag{5}$$

so the SLANT HEIGHT is

$$s = \sqrt{h^2 + \tfrac{1}{2}a^2} = b + c = \sqrt{\tfrac{1}{2}a^2 - r^2} + \sqrt{h^2 - r^2}. \tag{6}$$

Solving for h gives

$$h = \frac{ra}{\sqrt{a^2 - 2r^2}}. \tag{7}$$

We know, however, that the HEMISPHERE must be tangent to the sides, so $r = a/2$, and

$$h = \frac{\tfrac{1}{2}a}{\sqrt{a^2 - \tfrac{1}{2}a^2}}\,a = \frac{\tfrac{1}{2}}{\sqrt{\tfrac{1}{2}}}\,a = \tfrac{1}{2}\sqrt{2}a. \tag{8}$$

Fig. (c) shows a CROSS SECTION through the center, apex, and midpoints of opposite sides. The PYTHAGOREAN THEOREM once again gives

$$l = \sqrt{\tfrac{1}{4}a^2 + h^2} = \sqrt{\tfrac{1}{4}a^2 + \tfrac{1}{2}a^2} = \tfrac{1}{2}\sqrt{3}a. \tag{9}$$

We now need to find x and y.

$$\sqrt{\tfrac{1}{4}a^2 - x^2} + d = l. \tag{10}$$

But we know l and h, and d is given by

$$d = \sqrt{h^2 - x^2}. \tag{11}$$

so

$$\sqrt{\tfrac{1}{4}a^2 - x^2} + \sqrt{\tfrac{1}{2}a^2 - x^2} = \tfrac{1}{2}\sqrt{3}a. \tag{12}$$

Solving gives

$$x = \tfrac{1}{6}\sqrt{6}a, \tag{13}$$

so

$$y = \sqrt{r^2 - x^2} = \sqrt{\tfrac{1}{4} - \tfrac{1}{6}}\,a = \sqrt{\frac{3-2}{12}}\,a = \frac{a}{2\sqrt{3}}. \tag{14}$$

We can now find the AREA of the SPHERICAL CAP as

$$V_{\text{cap}} = \tfrac{1}{6}\pi H(3A^2 + H^2), \tag{15}$$

where

$$A \equiv y = \frac{a}{2\sqrt{3}} \tag{16}$$

$$H \equiv r - x = \tfrac{1}{2}a - \frac{a}{\sqrt{6}} = a\left(\frac{1}{2} - \frac{1}{\sqrt{6}}\right), \tag{17}$$

so

$$V_{\text{cap}} = \tfrac{1}{6}\pi a^3\left[3\left(\frac{1}{12}\right)+\left(\frac{1}{2}-\frac{1}{\sqrt{6}}\right)^2\right]\left(\frac{1}{2}-\frac{1}{\sqrt{6}}\right)$$

$$= \tfrac{1}{6}\pi a^3\left[\frac{1}{4}+\left(\frac{1}{4}+\frac{1}{6}-\frac{1}{\sqrt{6}}\right)\right]\left(\frac{1}{2}-\frac{1}{\sqrt{6}}\right)$$

$$= \tfrac{1}{6}\pi a^3\left(\frac{2}{3}-\frac{1}{\sqrt{6}}\right)\left(\frac{1}{2}-\frac{1}{\sqrt{6}}\right)$$

$$= \tfrac{1}{6}\pi a^3\left(\frac{1}{3}-\frac{1}{2\sqrt{6}}-\frac{2}{3\sqrt{6}}+\frac{1}{6}\right)$$

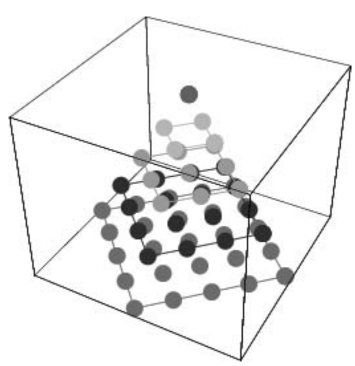
$$= \tfrac{1}{6}\pi a^3\left(\frac{1}{2}-\frac{7}{6\sqrt{6}}\right). \quad (18)$$

Therefore, the volume within the pyramid is

$$V_{\text{inside}} = \tfrac{2}{3}\pi r^3 - 4V_{cap} = \tfrac{2}{3}\pi\tfrac{1}{8}a^3 - \tfrac{2}{3}\pi a^3\left(\frac{1}{2}-\frac{7}{6\sqrt{6}}\right)$$

$$= \tfrac{2}{3}\pi a^3\left(\frac{1}{8}-\frac{1}{2}+\frac{7}{6\sqrt{6}}\right) = \tfrac{2}{3}\pi a^3\left(\frac{7}{6\sqrt{6}}-\frac{3}{8}\right)$$

$$= \pi a^3\left(\frac{7}{9\sqrt{6}}-\frac{1}{4}\right). \quad (19)$$



This problem appeared in the Japanese scholastic aptitude test (Cipra 1993).

Square Pyramidal Number

A FIGURATE NUMBER OF THE FORM

$$P_n = \tfrac{1}{6}n(n+1)(2n+1), \quad (1)$$

corresponding to a configuration of points which form a SQUARE PYRAMID, is called a square pyramidal number (or sometimes, simply a PYRAMIDAL NUMBER). The first few are 1, 5, 14, 30, 55, 91, 140, 204, ... (Sloane's A000330). They are sums of consecutive pairs of TETRAHEDRAL NUMBERS and satisfy

$$P_n = \tfrac{1}{3}(2n+1)T_n, \quad (2)$$

where T_n is the nth TRIANGULAR NUMBER.

The only numbers which are simultaneously SQUARE $S_m = m^2$ and square pyramidal $P_n = n(n+1)(2n+1)/6$ (the CANNONBALL PROBLEM) are $P_1 = 1$ and $P_{24} = 4900$, corresponding to $S_1 = 1$ and $S_{70} = 4900$ (Dickson 1952, p. 25; Ball and Coxeter 1987, p. 59; Ogilvy 1988), as conjectured by Lucas (1875, 1876) and proved by Watson (1918). The proof is far from elementary, and requires solving the DIOPHANTINE EQUATION

$$m^2 = \tfrac{1}{6}n(n+1)(2n+1) \quad (3)$$

(Guy 1994, p. 147). However, an elementary proof has also been given by a number of authors.

Numbers which are simultaneously TRIANGULAR $T_m = m(m+1)/2$ and square pyramidal $P_n = n(n+1)(2n+1)/6$ satisfy the DIOPHANTINE EQUATION

$$\tfrac{1}{2}m(m+1) = \tfrac{1}{6}n(n+1)(2n+1). \quad (4)$$

COMPLETING THE SQUARE gives

$$\tfrac{1}{2}\left(m+\tfrac{1}{2}\right)^2 - \tfrac{1}{8} = \tfrac{1}{6}\left(2n^3+3n^2+n\right) \quad (5)$$

$$\tfrac{1}{8}(2m+1)^2 = \tfrac{1}{6}\left(2n^3+3n^2+n\right)+\tfrac{1}{8} \quad (6)$$

$$3(2m+1)^2 = 8n^3+12n^2+4n+3. \quad (7)$$

The only solutions are $(n, m) = (-1, 0), (0, 0), (1, 1), (5, 10), (6, 13)$, and $(85, 645)$ (Guy 1994, p. 147), corresponding to the nontrivial triangular square pyramidal numbers 1, 55, 91, 208335.

Numbers which are simultaneously TETRAHEDRAL $Te_m = m(m+1)(m+2)/6$ and square pyramidal $P_n = n(n+1)(2n+1)/6$ satisfy the DIOPHANTINE EQUATION

$$m(m+1)(m+2) = n(n+1)(2n+1). \quad (8)$$

Beukers (1988) has studied the problem of finding solutions via integral points on an ELLIPTIC CURVE and found that the only solution is the trivial $Te_1 = P_1 = 1$.

Square Quadrants

The areas of the regions illustrated above can be found from the equations

$$A+4B+4C=1 \tag{1}$$

$$A+3B+2C=\tfrac{1}{4}\pi. \tag{2}$$

Since we want to solve for three variables, we need a third equation. This can be taken as

$$A+2B+C=2E+D, \tag{3}$$

where

$$D=\tfrac{1}{4}\sqrt{3} \tag{4}$$

$$D+E=\tfrac{1}{6}\pi, \tag{5}$$

leading to

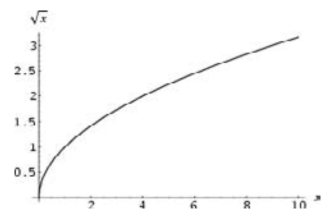
$$A+2B+C=D+2E=2(D+E)-D=\tfrac{1}{3}\pi-\tfrac{1}{4}\sqrt{3}. \tag{6}$$

Combining the equations (1), (2), and (6) gives the matrix equation

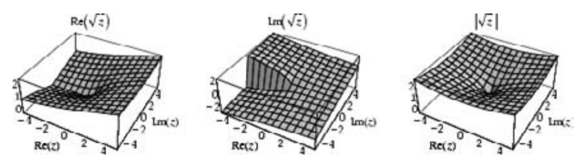
$$\begin{bmatrix}1 & 4 & 4\\ 1 & 3 & 2\\ 1 & 2 & 1\end{bmatrix}\begin{bmatrix}A\\ B\\ C\end{bmatrix}=\begin{bmatrix}1\\ \tfrac{1}{4}\pi\\ \tfrac{1}{3}\pi-\tfrac{1}{4}\sqrt{3}\end{bmatrix}, \tag{7}$$

which can be inverted to yield

$$A=1-\sqrt{3}-\tfrac{1}{3}\pi \tag{8}$$



$$B=-1+\tfrac{1}{2}\sqrt{3}+\tfrac{1}{12}\pi \tag{9}$$



$$C=1-\tfrac{1}{4}\sqrt{3}+\tfrac{1}{6}\pi. \tag{10}$$

Square Root

A square root of x is a number r such that $r^2=x$. Square roots are also called radicals or surds. Any positive real number has *two* square roots: one positive and one negative. For example, the square roots of 9 are $+3$ and -3, since $\{+3\}^2=\{-3\}^2=9$. Any nonnegative real number x has a unique nonnegative square root r; this is called the PRINCIPAL SQUARE ROOT and is written $r=x^{1/2}$ or $r=\sqrt{x}$. For example, the PRINCIPAL SQUARE ROOT of 9 is $\sqrt{9}=+3$, while the other square root of 9 is $-\sqrt{9}=-3$. In common usage, unless otherwise specified, "the" square root is generally taken to mean the principal square root. The function $\sqrt{x}$ is the INVERSE FUNCTION of $f(x)=x^2$, for $x\geq 0$.

Any nonzero COMPLEX NUMBER z has two square roots. For example, using the IMAGINARY UNIT I, the two square roots of -9 are $\pm\sqrt{-9}=\pm 3i$. The PRINCIPAL SQUARE ROOT of a number z is returned by the *Mathematica* `Sqrt[x]`.

The square root of 2 is the IRRATIONAL NUMBER $\sqrt{2}=1.41421356$ (Sloane's A002193), which has the simple periodic CONTINUED FRACTION 1, 2, 2, 2, 2, 2, ... (Sloane's A040000). The square root of 3 is the

IRRATIONAL NUMBER $\sqrt{3} \approx 1.73205081$ (Sloane's A002194), which has the simple periodic CONTINUED FRACTION 1, 1, 2, 1, 2, 1, 2, ... (Sloane's A040001). In general, the CONTINUED FRACTIONS of the square roots of all POSITIVE INTEGERS are periodic.

The square roots of a COMPLEX NUMBER $z = x + iy$ are given by

$$\sqrt{x+iy} = \pm\sqrt{x^2+y^2} \times \left\{ \cos\left[\frac{1}{2}\tan^{-1}\left(\frac{y}{x}\right)\right] + i\sin\left[\frac{1}{2}\tan^{-1}\left(\frac{y}{x}\right)\right]\right\}. \quad (1)$$

In addition,

$$\sqrt{x+iy} = \pm\tfrac{1}{2}\sqrt{2}\left[\sqrt{\sqrt{x^2+y^2}+x} + i\,\mathrm{sgn}(y)\sqrt{\sqrt{x^2+y^2}-x}\right]. \quad (2)$$

As can be seen in the above figure, the IMAGINARY PART of the complex square root function has a BRANCH CUT along the NEGATIVE real axis.

A NESTED RADICAL OF THE FORM $\sqrt{a \pm b\sqrt{c}}$ can sometimes be simplified into a simple square root by equating

$$\sqrt{a \pm b\sqrt{c}} = \sqrt{d} \pm \sqrt{e}. \quad (3)$$

Squaring gives

$$a \pm b\sqrt{c} = d + e \pm 2\sqrt{de}. \quad (4)$$

so

$$a = d + e \quad (5)$$

$$b^2 c = 4de. \quad (6)$$

Solving for d and e gives

$$d,\ e = \frac{a \pm \sqrt{a^2 - b^2 c}}{2}. \quad (7)$$

For example,

$$\sqrt{5+2\sqrt{6}} = \sqrt{2} + \sqrt{3} \quad (8)$$

$$\sqrt{3-2\sqrt{2}} = \sqrt{2} - 1. \quad (9)$$

The `Simplify` command of *Mathematica* does not apply such simplifications, but `FullSimplify` does. In general, radical denesting is a difficult problem (Landau).

A sequence of approximations a/b to $\sqrt{n}$ can be derived by factoring

$$a^2 - nb^2 = \pm 1 \quad (10)$$

(where -1 is possible only if -1 is a QUADRATIC RESIDUE of n). Then

$$(a+b\sqrt{n})(a-b\sqrt{n}) = \pm 1 \quad (11)$$

$$(a+b\sqrt{n})^k (a-b\sqrt{n})^k = (\pm 1)^k = \pm 1, \quad (12)$$

and

$$(1+\sqrt{n})^1 = 1 + \sqrt{n} \quad (13)$$

$$(1+\sqrt{n})^2 = (1+n) + 2\sqrt{n} \quad (14)$$

$$(1+\sqrt{n})(a+b\sqrt{n}) = (a+bn) + \sqrt{n}(a+b). \quad (15)$$

Therefore, a and b are given by the RECURRENCE RELATIONS

$$a_i = a_{i-1} + b_{i-1} n \quad (16)$$

$$b_i = a_{i-1} + b_{i-1} \quad (17)$$

with $a_1 = b_1 = 1$. The error obtained using this method is

$$\left|\frac{a}{b} - \sqrt{n}\right| = \frac{1}{b(a+b\sqrt{n})} < \frac{1}{2b^2}. \quad (18)$$

The first few approximants to $\sqrt{n}$ are therefore given by

$$1,\ \tfrac{1}{2}(1+n),\ \frac{1+3n}{3+n},\ \frac{1+6n+n^2}{4(n+1)},\ \frac{1+10n+5n^2}{5+10n+n^2},\ \ldots \quad (19)$$

This ALGORITHM is sometimes known as the BHASKARA-BROUCKNER ALGORITHM. For the case $n = 2$, this gives the convergents to $\sqrt{2}$ as 1, 3/2, 7/5, 17/12, 41/29, 99/70, ... (Sloane's A001333 and A000129; Wells 1986, p. 34). The numerators are given by the RECURRENCE RELATION

$$a(n) = 2a(n-1) + a(n-2), \quad (20)$$

and the denominators are the PELL NUMBERS.

Another general technique for deriving this sequence, known as NEWTON'S ITERATION, is obtained by letting $x = \sqrt{n}$. Then $x = n/x$, so the SEQUENCE

$$x_k = \frac{1}{2}\left(x_{k-1} + \frac{n}{x_{k-1}}\right) \quad (21)$$

converges quadratically to the root. The first few approximants to $\sqrt{n}$ are therefore given by

$$1,\ \tfrac{1}{2}(1+n),\ \frac{1+6n+n^2}{4(n+1)},\ \frac{1+28n+70n^2+28n^3+n^4}{8(1+n)(1+6n+n^2)},\ \ldots \quad (22)$$

For $\sqrt{2}$, this gives the convergents 1, 3/2, 17/12, 577/408, 665857/470832, ... (Sloane's A051008 and A051009).

Square Root Inequality

$$2\sqrt{n+1}-2\sqrt{n}<\frac{1}{\sqrt{n}}<2\sqrt{n}-2\sqrt{n-1}.$$

Square Root Method

The square root method is an algorithm which solves the MATRIX EQUATION

$$\mathsf{A}\mathbf{u}=\mathbf{g} \tag{1}$$

for $\mathbf{u}$, with A a $p \times p$ SYMMETRIC MATRIX and $\mathbf{g}$ a given VECTOR. Convert A to a TRIANGULAR MATRIX such that

$$\mathsf{T}^{\mathrm{T}}\mathsf{T}=\mathsf{A}, \tag{2}$$

where T^{T} is the MATRIX TRANSPOSE. Then

$$\mathsf{T}^{\mathrm{T}}\mathbf{k}=\mathbf{g} \tag{3}$$

$$\mathsf{T}\mathbf{u}=\mathbf{k}, \tag{4}$$

so

$$\mathsf{T}=\begin{bmatrix} s_{11} & s_{12} & \cdots & \cdots \\ 0 & s_{22} & \cdots & \cdots \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & s_{pp} \end{bmatrix}. \tag{5}$$

giving the equations

$$s_{11}^2=a_{11}$$

$$s_{11}s_{12}=a_{12}$$

$$s_{12}^2+s_{22}^2=a_{22}$$

$$s_{1j}^2+s_{2j}^2+\ldots+s_{jj}^2=a_{jj}$$

$$s_{1j}+s_{2j}s_{2k}+\ldots+s_{jj}s_{jk}=a_{jk}. \tag{6}$$

These give

$$s_{11}=\sqrt{a_{11}}$$

$$s_{12}=\frac{a_{12}}{s_{11}}$$

$$s_{22}=\sqrt{a_{22}-s_{12}^2}$$

$$S_{jj}=\sqrt{a_{jj}-s_{ij}^2-s_{2j}^2-\ldots-s_{j-1,\,j}^2}$$

$$s_{jk}=\frac{a_{jk}-s_{1j}s_{1k}-s_{2j}s_{2k}-\ldots-s_{j-1,\,j}s_{j-1,\,k}}{s_{jj}}, \tag{7}$$

giving T from A. Now solve for $\mathbf{k}$ in terms of the s_{ij} s and $\mathbf{g}$,

$$s_{11}k_1=g_1$$

$$s_{12}k_1+s_{22}k_2=g_2$$

$$s_{1j}k_1+s_{2j}k_2+\ldots+s_{jj}k_j=g_j, \tag{8}$$

which gives

$$k_1=\frac{g_1}{s_{11}}$$

$$k_2=\frac{g_2-s_{12}k_1}{s_{22}}$$

$$k_j=\frac{g_j-s_{1j}k_1-s_{2j}k_2-\ldots-s_{j-1,\,j}k_{j-1}}{s_{jj}}. \tag{9}$$

Finally, find $\mathbf{u}$ from the s_{ij} s and $\mathbf{k}$,

$$s_{11}u_1+s_{12}u_2\ldots+s_{1p}u_p=k_1$$

$$s_{22}u_2+\ldots+s_{2p}u_p=k_2$$

$$s_{pp}u_p=k_p, \tag{10}$$

giving the desired solution,

$$u_p=\frac{k_p}{s_{pp}}$$

$$u_{p-1}=\frac{k_{p-1}-s_{p-1,\,p}u_p}{s_{p-1,\,p-1}}$$

$$u_j=\frac{k_j-s_{j,\,j+1}u_{j+1}-s_{j,\,j+2}u_{j+2}-\ldots-s_{jp}u_p}{s_{jj}}. \tag{11}$$

Square Tiling

There are a number of interesting results related to the tiling of squares. For example, M. Laczkovich has shown that there are exactly three shapes of non-

right triangles that tile the square with similar copies, corresponding to angles ($\pi/8$, $\pi/4$, $5\pi/8$), ($\pi/4$, $\pi/3$, $5\pi/12$), and ($\pi/12$, $\pi/4$, $2\pi/3$) (Stein and Szabó 1994). In particular, given triangles of shape $1-2-\sqrt{5}$ with no two the same size, tile the square. The best known solution has 8 triangles (Berlekamp 1999).

Square Torus

The square torus is the quotient of the plane by the integer lattice.

Square Triangle Picking

Given three points chosen at random inside a UNIT SQUARE, the average AREA of the TRIANGLE determined by these points is given by

$$\bar{A}=\frac{\underbrace{\int_0^1\cdots\int_0^1}_{6}|A(\mathbf{x}_i)|\,dx_1\cdots dx_3\,dy_1\cdots dy_3}{\underbrace{\int_0^1\cdots\int_0^1}_{6}dx_1\cdots dx_3\,dy_1\cdots dy_3},$$

where the VERTICES are located at $(x_i,\ y_i)$ where $i=1$, ..., 3, and the (signed) AREA is given by the DETERMINANT

$$A=\frac{1}{2!}\begin{vmatrix}x_1 & y_1 & 1\\ x_2 & y_2 & 1\\ x_3 & y_3 & 1\end{vmatrix}.$$

The integral can be evaluated analytically to yield $\bar{A}=11/144$ (Ambartzumian 1987, Pfiefer, Trott 1998), and first calculated by Woolhouse (1867). Because attempting to do the integrals directly quickly results in intractable integrands, the best approach to accomplish the integration is to divide the 6-dimensional region of integration into subregions such that the sign of A does not change (Trott 1998).

The distribution function for the area of a random triangle in a square is known exactly.

Square Triangular Number

A number which is simultaneously SQUARE and TRIANGULAR. Let T_n denote the nth TRIANGULAR NUMBER and S_m the mth SQUARE NUMBER, then a number which is both triangular and square satisfies the equation $T_n=S_m$, or

$$\tfrac{1}{2}n(n+1)=m^2. \tag{1}$$

COMPLETING THE SQUARE gives

$$\tfrac{1}{2}(n^2+n)=\tfrac{1}{2}\left(n+\tfrac{1}{2}\right)^2-\left(\tfrac{1}{2}\right)\left(\tfrac{1}{4}\right)=m^2 \tag{2}$$

$$\tfrac{1}{8}(2n+1)^2-\tfrac{1}{8}=m^2 \tag{3}$$

$$(2n+1)^2-8m^2=1. \tag{4}$$

Therefore, defining

$$x\equiv 2n+1 \tag{5}$$

$$y\equiv 2m \tag{6}$$

gives the PELL EQUATION

$$x^2-2y^2=1 \tag{7}$$

(Conway and Guy 1996). The first few solutions are

$(x, y) = (3, 2), (17, 12), (99, 70), (577, 408), \ldots$ These give the solutions $(n, m) = (1, 1), (8, 6), (49, 35), (288, 204), \ldots$ (Sloane's A001108 and A001109), corresponding to the triangular square numbers 1, 36, 1225, 41616, 1413721, 48024900, ... (Sloane's A001110; Pietenpol 1962). In 1730, Euler showed that there are an infinite number of such solutions (Dickson 1952).

The general FORMULA for a square triangular number ST_n is b^2c^2, where b/c is the nth convergent to the CONTINUED FRACTION of $\sqrt{2}$ (Ball and Coxeter 1987, p. 59; Conway and Guy 1996). The first few are

$$\frac{1}{1}, \frac{3}{2}, \frac{7}{5}, \frac{17}{12}, \frac{41}{29}, \frac{99}{70}, \frac{239}{169}, \ldots, \tag{8}$$

The NUMERATORS and DENOMINATORS can also be obtained by doubling the previous FRACTION and adding to the FRACTION before that.

A general FORMULA for square triangular numbers is

$$ST_n = \left[\frac{(1+\sqrt{2})^{2n} - (1-\sqrt{2})^{2n}}{4\sqrt{2}}\right]^2 \tag{9}$$

$$= \tfrac{1}{32}\left[\left(17+2\sqrt{2}\right)^n + \left(17-2\sqrt{2}\right)^n - 2\right]. \tag{10}$$

The square triangular numbers also satisfy the RECURRENCE RELATION

$$ST_n = 34ST_{n-1} - ST_{n-2} + 2 \tag{11}$$

$$u_{n+2} = 6u_{n+1} - u_n \tag{12}$$

with $u_0 = 0$, $u_1 = 1$, where $ST_n \equiv u_n^2$. A curious product formula for ST_n is given by

$$ST_n = 2^{2n-5} \prod_{k=1}^{2n} \left[3 + \cos\left(\frac{k\pi}{n}\right)\right]. \tag{13}$$

An amazing GENERATING FUNCTION is

$$f(x) = \frac{1+x}{(1-x)(1-34x+x^2)}$$

$$= 1 + 36x + 1225x^2 + \ldots \tag{14}$$

(Sloane and Plouffe 1995).

Taking the square and triangular numbers together gives the sequence 1, 1, 3, 4, 6, 9, 10, 15, 16, 21, 25, ... (Sloane's A005214; Hofstadter 1996, p. 15).

Square Wave

The square wave is a periodic waveform consisting of instantaneous transitions between two levels which can be denoted ± 1. The square wave is sometimes also called the RADEMACHER FUNCTION. Let the square wave have period $2L$. The square wave function is ODD, so the FOURIER SERIES has $a_0 = a_n = 0$ and

$$b_0 = \frac{2}{L}\int_0^L \sin\left(\frac{n\pi x}{L}\right) dx$$

$$= \frac{4}{n\pi}\sin^2\left(\tfrac{1}{2}n\pi\right) = \frac{4}{n\pi}\begin{cases} 0 & n \text{ even} \\ 1 & n \text{ odd.}\end{cases}$$

The FOURIER SERIES for the square wave is therefore

$$f(x) = \frac{4}{\pi}\sum_{n=1,3,5,\ldots}^{\infty} \frac{1}{n}\sin\left(\frac{n\pi x}{L}\right).$$

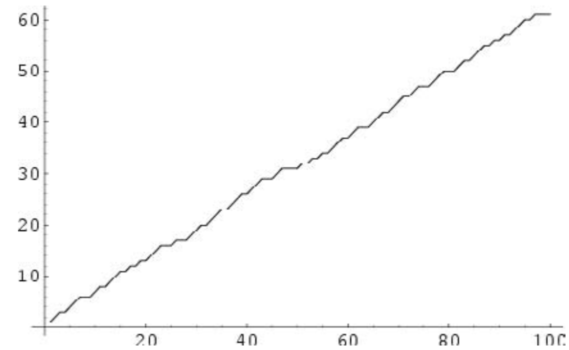
Squared



A number to the POWER 2 is said to be squared, so that x^2 is called "x squared."

See also CUBED, SQUARE ROOT

Squared Square

PERFECT SQUARE DISSECTION

Squarefree

A number is said to be squarefree (or sometimes QUADRATFREI; Shanks 1993) if its PRIME decomposition contains no repeated factors. All PRIMES are therefore trivially squarefree. The squarefree numbers are 1, 2, 3, 5, 6, 7, 10, 11, 13, 14, 15, ... (Sloane's A005117). The SQUAREFUL numbers (i.e., those that contain at least one square) are 4, 8, 9, 12, 16, 18, 20, 24, 25, ... (Sloane's A013929).

The asymptotic number $Q(n)$ of squarefree numbers $\leq n$ is given by

$$Q(n) = \frac{6n}{\pi^2} + \mathcal{O}\left(\sqrt{n}\right) \tag{1}$$

(Landau 1974, pp. 604–09; Nagell 1951, p. 130; Hardy and Wright 1979, pp. 269–70; Hardy 1999, p. 65). $Q(n)$ for $n = 10$, 100, 1000, ... are 7, 61, 608, 6083, 60794, 607926, ..., while the asymptotic density is $1/\zeta(2) = 6/\pi^2 \approx 0.607927$, where $\zeta(n)$ is the RIEMANN ZETA FUNCTION.

The MÖBIUS FUNCTION is given by

$$\mu(n) \equiv \begin{cases} 0 & \text{if } n \text{ has one or more repeated prime factors} \\ 1 & \text{if } n = 1 \\ (-1)^k & \text{if } n \text{ is the product of } k \text{ distinct primes,} \end{cases} \tag{2}$$

so $\mu(n) \neq 0$ indicates that n is squarefree. The asymptotic formula for $Q(x)$ is equivalent to the formula

$$\sum_{n=1}^{x} |\mu(n)| = \frac{6x}{\pi^2} + \mathcal{O}\left(\sqrt{x}\right) \tag{3}$$

(Hardy and Wright 1979, p. 270)

There is no known polynomial-time algorithm for recognizing squarefree INTEGERS or for computing the squarefree part of an INTEGER. In fact, this problem may be no easier than the general problem of integer factorization (obviously, if an integer n can be factored completely, n is squarefree IFF it contains no duplicated factors). This problem is an important unsolved problem in NUMBER THEORY because computing the RING of integers of an algebraic number field is reducible to computing the squarefree part of an INTEGER (Lenstra 1992, Pohst and Zassenhaus 1997). The *Mathematica* function `SquareFreeQ[n]` in the *Mathematica* add-on package `NumberTheory`NumberTheoryFunctions`` (which can be loaded with the command `<<NumberTheory``) determines whether a number is squarefree.

No SQUAREFUL FIBONACCI NUMBERS F_p are known with p PRIME. All numbers less than 2.5×10^{15} in SYLVESTER'S SEQUENCE are squarefree, and no SQUAREFUL numbers in this sequence are known (Vardi 1991). Every CARMICHAEL NUMBER is squarefree. The BINOMIAL COEFFICIENTS $\binom{2n-1}{n}$ are squarefree only for $n = 2$, 3, 4, 6, 9, 10, 12, 36, ..., with no others less than $n = 1500$. The CENTRAL BINOMIAL COEFFICIENTS are SQUAREFREE only for $n = 1$, 2, 3, 4, 5, 7, 8, 11, 17, 19, 23, 71, ... (Sloane's A046098), with no others less than 1500.

Square-Free

SQUAREFREE

Squarefree Part

That part of a POSITIVE INTEGER left after all square factors are divided out. For example, the squarefree part of $24 = 2^3 \cdot 3$ is 6, since $6 \cdot 2^2 = 24$. For $n = 1, 2, ...$, the first few are 1, 2, 3, 1, 5, 6, 7, 2, 1, 10, ... (Sloane's A007913). The squarefree part function can be implemented in *Mathematica* as

```
SquarefreePart[n_Integer?Positive] :=
 Times @@ Power @@@ ({#[[1]], Mod[#[[2]], 2]} &
/@ FactorInteger[n])
```

Squarefree Word

N.B. A detailed online essay by S. Finch was the starting point for this entry.

A "square" word consists of two identical adjacent subwords (for example, *acbacb*). A squarefree word contains *no* square words as subwords (for example, *abcacbabcb*). The only squarefree binary words are *a*, *b*, *ab*, *ba*, *aba*, and *bab* (since *aa*, *bb*, *aaa*, *aab*, *abb*, *baa*, *bba*, and *bbb* contain square identical adjacent subwords *a*, *b*, *a*, *a*, *b*, *a*, *b*, and *b*, respectively).

However, there are arbitrarily long ternary squarefree words. The number $s(n)$ of ternary squarefree words of length $n = 1, 2, ...$ are 1, 3, 6, 12, 18, 30, 42, 60, ... (Sloane's A006156), and $s(n)$ is bounded by

$$6 \cdot 1.032^n \leq s(n) \leq 6 \cdot 1.379^n \qquad (1)$$

(Brandenburg 1983). In addition,

$$S \equiv \lim_{n\to\infty} [s(n)]^{1/n} = 1.302\ldots \qquad (2)$$

(Brinkhuis 1983, Noonan and Zeilberger 1997).

The number of squarefree quaternary words of length $n = 1, 2, ...$ are 4, 12, 36, 96, 264, 696, ... (Sloane's A051041).

Squareful

A number is squareful, also called nonsquarefree, if it contains at least one SQUARE in its prime factorization. The first few are 4, 8, 9, 12, 16, 18, 20, 24, 25, ... (Sloane's A013929). The greatest multiple prime factors for the squareful integers are 2, 2, 3, 2, 2, 3, 2, 2, 5, 3, 2, 2, 3, ... (Sloane's A046028). The least multiple prime factors for squareful integers are 2, 2, 3, 2, 2, 3, 2, 2, 5, 3, 2, 2, 2, ... (Sloane's A046027).

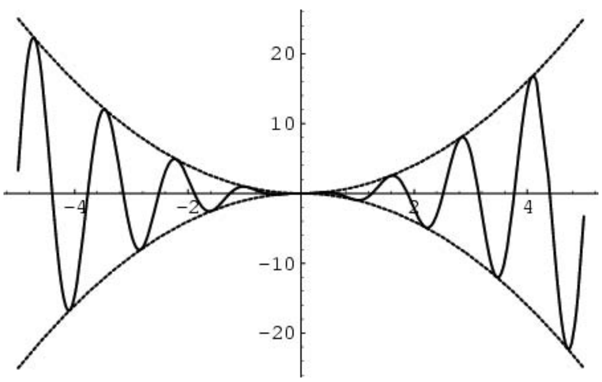
Squaring



Squaring is the GEOMETRIC CONSTRUCTION, using only COMPASS and STRAIGHTEDGE, of a SQUARE which has the same area as a given geometric figure. Squaring is also called QUADRATURE. An object which can be constructed by squaring is called SQUARABLE.

See also CIRCLE SQUARING, COMPASS, CONSTRUCTIBLE NUMBER, GEOMETRIC CONSTRUCTION, RECTANGLE SQUARING, STRAIGHTEDGE, TRIANGLE SQUARING

Squaring the Circle

CIRCLE SQUARING

Squeezing Theorem

Let there be two functions $f_-(x)$ and $f_+(x)$ such that $f(x)$ is "squeezed" between the two,

$$f_-(x) \le f(x) \le f_+(x).$$

If

$$r = \lim_{x \to a} f_-(x) = \lim_{x \to a} f_+(x),$$

then $\lim_{x\to a} f(x) = r$. In the above diagram the functions $f_-(x) = -x^2$ and $f_+(x) = x^2$ "squeeze" $x^2 \sin(cx)$ at 0, so $\lim_{x\to a} x^2 \sin(cx) = 0$. The squeezing theorem is also called the sandwich theorem.

See also LIMIT, PINCHING THEOREM

s-Run

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let $\mathbf{v}$ be a n-VECTOR whose entries are each 1 (with probability p) or 0 (with probability $q = 1-p$). An s-run is an isolated group of s consecutive 1s. Ignoring the boundaries, the total number of runs R_n satisfies

$$K_n = \frac{\langle R_n \rangle}{n} = (1-p)^2 \sum_{s=1}^{n} p^s = p(1-p)(1-p^n),$$

so

$$K(p) \equiv \lim_{n\to\infty} K_n = p(1-p),$$

which is called the MEAN RUN COUNT PER SITE or MEAN RUN DENSITY in PERCOLATION THEORY.

See also PERCOLATION THEORY, s-CLUSTER

SIGNATURE (RECURRENCE RELATION)

SSS Theorem

Specifying three sides uniquely determines a TRIANGLE whose AREA is given by HERON'S FORMULA,

$$A = \sqrt{s(s-a)(s-b)(s-c)}, \quad (1)$$

where

$$s \equiv \tfrac{1}{2}(a+b+c) \quad (2)$$

is the SEMIPERIMETER of the TRIANGLE. Let R be the CIRCUMRADIUS, then

$$A = \frac{abc}{4R}. \quad (3)$$

Using the LAW OF COSINES

$$a^2 = b^2 + c^2 - 2bc \cos A \quad (4)$$

$$b^2 = a^2 + c^2 - 2ac \cos B \quad (5)$$

$$c^2 = a^2 + b^2 - 2ab \cos C \quad (6)$$

gives the three ANGLES as

$$A = \cos^{-1}\left(\frac{b^2 + c^2 - a^2}{2bc}\right) \quad (7)$$

$$B = \cos^{-1}\left(\frac{a^2 + c^2 - b^2}{2ac}\right) \quad (8)$$

$$C = \cos^{-1}\left(\frac{a^2 + b^2 - c^2}{2ab}\right). \quad (9)$$

St. Ives Problem

A well-known nursery rhyme states, "As I was going to St. Ives, I met a man with seven wives. Every wife had seven sacks, every sack had seven cats, every cat had seven kitts. Kitts, cats, sacks, wives, how many were going to St. Ives?" Upon being presented with this conundrum, most readers begin furiously adding and multiplying numbers in order to calculate the total quantity of objects mentioned. However, the problem is a trick question. Since the man and his wives, sacks, etc. were met by the narrator *on the way to St. Ives*, they were in fact leaving–not going to–St. Ives. The number *going to* St. Ives is therefore "one," i.e., the narrator.

Should a diligent reader nevertheless wish to calculate the sum total N of kitts, cats, sacks, and wives, the answer is easily given by the GEOMETRIC SERIES

$$\sum_{k=1}^{n} r^k = \frac{r(1 - r^n)}{1 - r} \quad (1)$$

with $n = 4$ and $r = 7$. Therefore,

$$N = \sum_{i=1}^{4} 7^i = \frac{7(1 - 7^4)}{7 - 1} = 2800. \quad (2)$$

$$N = 7^1 + 7^2 + 7^3 + 7^4$$
$$= 7(1 + 7(1 + 7(1 + 7))) = 7(1 + 7(1 + 7 \cdot 8))$$
$$= 7(1 + 7 \cdot 57) = 7 \cdot 400 = 2800. \quad (3)$$

A similar question was given as problem 79 of the Rhind papyrus, dating from 1650 BC. This problem concerns 7 houses, each with 7 cats, each with 7 mice, each with 7 spelt, each with 7 hekat. The total number of items is then

$$\sum_{i=1}^{5} 7^i = 19607 \quad (4)$$

(Wells 1986, p. 71). In turn, the problem of the Rhind papyrus is repeated in Fibonacci's *Liber Abaci* (1202, 1228).

Stability

The robustness of a given outcome to small changes in initial conditions or small random fluctuations. CHAOS is an example of a process which is not stable.

See also STABILITY MATRIX

Stability Matrix

Given a system of two ordinary differential equations

$$\dot{x} = f(x, y) \quad (1)$$

$$\dot{y} = g(x, y), \quad (2)$$

let x_0 and y_0 denote FIXED POINTS with $\dot{x} = \dot{y} = 0$, so

$$f(x_0, y_0) = 0 \quad (3)$$

$$g(x_0, y_0) = 0. \quad (4)$$

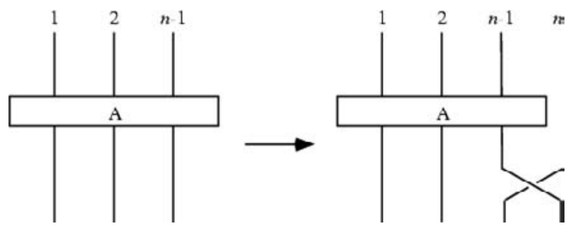
Then expand about (x_0, y_0) so

$$\delta\dot{x} = f_x(x_0, y_0)\delta x + f_y(x_0, y_0)\delta y + f_{xy}(x_0, y_0)\delta x \delta y + \ldots \quad (5)$$

$$\delta\dot{y} = g_x(x_0, y_0)\delta x + g_y(x_0, y_0)\delta y + g_{xy}(x_0, y_0)\delta x \delta y + \ldots \quad (6)$$

To first-order, this gives

$$\frac{d}{dt}\begin{bmatrix}\delta x\\ \delta y\end{bmatrix} - \begin{bmatrix} f_x(x_0, y_0) & f_y(x_0, y_0)\\ g_x(x_0, y_0) & g_y(x_0, y_0)\end{bmatrix}\begin{bmatrix}\delta x\\ \delta y\end{bmatrix}, \quad (7)$$



where the 2×2 MATRIX, or its generalization to higher dimension, is called the stability matrix. Analysis of the EIGENVALUES (and EIGENVECTORS) of the stability matrix characterizes the type of FIXED POINT.

Stable Marriage Problem

Given a set of n men and n women, marry them off in pairs after each man has ranked the women in order of preference from 1 to n, $\{w_1, \ldots, w_n\}$ and each women has done likewise, $\{m_1, \ldots, m_n\}$. If the resulting set of marriages contains no pairs OF THE FORM $\{m_i, w_j\}$, $\{m_k, w_l\}$ such that m_i prefers w_l to w_j and w_l prefers m_i to m_k, the marriage is said to be stable. Gale and Shapley (1962) showed that a stable marriage exists for any choice of rankings (Skiena 1990, p. 245). In the United States, the algorithm of Gale and Shapley (1962) is used to match hospitals to medical interns (Skiena 1990, p. 245).

men's rankings

7	5	4	9	2	2	1	5	6
3	4	8	7	6	7	6	6	1
8	8	3	4	4	8	2	9	4
9	3	9	2	9	6	3	1	7
6	1	7	5	8	5	8	2	5
4	2	5	8	7	3	5	8	8
2	6	6	3	5	4	4	4	3
1	7	1	1	1	1	9	3	9
5	9	2	6	3	9	7	7	2

women's rankings

3	9	3	8	6	2	9	6	8
1	4	1	7	9	4	3	3	2
5	8	8	5	2	5	8	2	6
2	1	9	3	5	1	2	1	4
8	7	5	2	1	6	7	8	9
7	6	4	6	4	8	5	4	1
6	3	2	4	7	3	4	5	3
9	2	6	9	3	9	6	9	7
4	5	7	1	8	7	1	7	5

In the rankings illustrated above, the male-optimal stable marriage is 4, 2, 6, 5, 3, 1, 7, 9, 8, and the female-optimal stable marriage is 1, 2, 8, 9, 3, 4, 7, 6, 5. A stable marriage can be found using `StableMarriage[m, w]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<< DiscreteMath``).

Stable Polynomial

A REAL POLYNOMIAL P is said to be stable if all its ROOTS lie in the LEFT HALF-PLANE. The term "stable" is used to describe such a polynomial because, in the theory of linear servomechanisms, a system exhibits unforced time-dependent motion of the form e^{st}, where s is the root of a certain REAL POLYNOMIAL $P(s) = 0$. A system is therefore mechanically stable IFF P is a stable polynomial.

The polynomial $x + a$ is stable IFF $a > 0$, and the IRREDUCIBLE POLYNOMIAL $x^2 + ab + b$ is stable IFF both a and b are greater than zero. The ROUTH-HURWITZ THEOREM can be used to determine if a polynomial is stable.

Given two real polynomials P and Q, if P and Q are stable, then so is their product PQ, and vice versa (Séroul 2000, p. 280). It therefore follows that the coefficients of stable real polynomials are either all positive or all negative (although this is not a SUFFICIENT condition, as shown with the counterexample $x^3 + x^2 + x + 1$). Furthermore, the values of a stable polynomial are never zero for $x \geq 0$ and have the same sign as the coefficients of the polynomial.

It is possible to decide if a polynomial is stable without first knowing its roots using the following theorem due to Strelitz (1977). Let $A = x^n + a_{n-1}x^{n-1} + \ldots + a_0$ be a real polynomial with roots α_1, ..., α_n, and construct $B = x^m + b_{m-1}x^{m-1} + \ldots + b_0$ as the monic real polynomial of degree $m = n(n-1)/2$ having roots $\alpha_i + \alpha_j$ for $1 \leq i \leq j \leq n$. Then A is stable IFF all coefficients of A and B are positive (Séroul 2000, p. 281).

For example, given the third-order polynomial $A = x^3 + ax^2 + bx + c$, the sum-of-roots polynomial B is given by

$$B = x^3 + 2ax^2 + (a^2 + b)x + (ab - c). \tag{1}$$

Resolving the inequalities given by requiring that each coefficient of A and B be greater than zero then gives the conditions for A to be stable as $a > 0$, $b > 0$, $0 < c < ab$.

Similarly, for the fourth-order polynomial $A = x^4 + ax^3 + bx^2 + cx + d$, the sum-of-roots-polynomial is

$$x^6 + 3ax^5 + (3a^2 + 2b)x^4 + (a^3 + 4ab)x^3$$
$$+(2a^2b + b^2 + ac - 4d)x^2 + (ab^2 + a^2c - 4ad)$$
$$+x + (abc - c^2 - a^2d), \tag{2}$$

so the condition for A to be stable can be resolved to $a > 0$, $b > 0$, $0 < c < ab$, $0 < d < (abc - c^2)/a^2$.

The fifth-order polynomial is

$$x^{10} + 4ax^9 + (6a^2 + 3b)x^8 + (4a^3 + 9ab + c)x^7$$
$$+(a^4 + 9a^2b + 3b^2 + 4ac - 3d)x^6$$
$$+(3a^3b + 6ab^2 + 5a^2c + 2bc - 5ad - 11e)x^5$$
$$+(3a^2b^2 + b^3 + 2a^3c + 6abc - c^2 - 2a^2d - 2bd - 22ae)x^4$$
$$+(ab^3 + 4a^2bc + b^2c - 4cd - 16a^2e - 4be)x^3$$
$$+(2ab^2c + a^2c^2 - bc^2 + a^2bd + b^2d - 3acd - 4d^2 - 4a^3e$$
$$-9abe + 7ce)x^2$$
$$+(abc^2 - c^3 + ab^2d - 4ad^2 - 4a^2be - b^2e + 4ace + 4de)x$$
$$+(abcd - c^2d - a^2d^2 - ab^2e + bce + 2ade - e^2). \tag{3}$$

The following *Mathematica* code computes the sum-of-roots polynomial B and inequalities obtained from the coefficients,

```
RootSumPolynomial[r_List,x_]:=Module[
    {n=Length[r],i,j},
    RootReduce@Collect[Expand[
     Times@@((x-#)&/@Flatten[
      Table[r[[i]]+r[[j]],{i,n},{j,i+1,n}]]])
    ],x]
  ]  RootSumPolynomial[p_?PolynomialQ,x_]:=
           RootSumPolynomial[RootList[p,x],x]
RootList[p_?PolynomialQ,x_]:=
    x/.{ToRules[Roots[p==0,x,
     Cubics->False,Quartics->False
                                        ]]}
RootSumInequalities[p_?PolynomialQ,x_]:=
  And@@(#>0&/@Flatten[CoefficientList[#,x]&/@
    {RootSumPolynomial[p,x],p}])
```

while the following reduces the inequalities to a minimal set in the cubic case.

```
Resolve[Exists[x, (a | b | c | x) \[Element]
Reals,
   RootSumInequalities[x^3 + a x^2 + b x + c,
x]
  ], {a, b, c}]
```

Stab-Werner Projection

WERNER PROJECTION

Stack

A DATA STRUCTURE which is a special kind of LIST in which elements may be added to or removed from the top only. These actions are called a PUSH or a POP, respectively. Actions may be taken by popping one or more values, operating on them, and then pushing the result back onto the stack.

Stacks are used as the basis for computer languages such as FORTH, PostScript ® (Adobe Systems), and the RPN language used in Hewlett-Packard ® programmable calculators.

See also LIST, POP, PUSH, QUEUE, REVERSE POLISH NOTATION

Stack Polygon

[A, B, C]

A SELF-AVOIDING POLYGON containing two adjacent corners of its minimal bounding rectangle. The anisotropic area and perimeter generating function $G(x, y)$ and partial generating functions $H_m(y)$, connected by

$$G(x, y, q) = \sum_{m \geq 1} H_m(y, q) x^m.$$

satisfy the self-reciprocity and inversion relations

$$H_m(1/y, 1/q) = -y^{2m-3} q^{m^2-2m} H_m(y, q)$$

and

$$G(x, y) + y^3 G(x/y^2, 1/y) = 0$$

(Bousquet-Mélou *et al.* 1999).

Stäckel Determinant

A DETERMINANT used to determine in which coordinate systems the HELMHOLTZ DIFFERENTIAL EQUATION is separable (Morse and Feshbach 1953). A determinant

$$S = |\Phi_{mn}| = \begin{vmatrix} \Phi_{11} & \Phi_{12} & \Phi_{13} \\ \Phi_{21} & \Phi_{22} & \Phi_{23} \\ \Phi_{31} & \Phi_{32} & \Phi_{33} \end{vmatrix} \tag{1}$$

in which Φ_m are functions of u_i alone is called a Stäckel determinant. A coordinate system is separable if it obeys the ROBERTSON CONDITION, namely that the SCALE FACTORS h_i in the LAPLACIAN

$$\nabla^2 = \sum_{i=1}^{3} \frac{1}{h_1 h_2 h_3} \frac{\partial}{\partial u_i} \left(\frac{h_1 h_2 h_3}{h_i^2} \frac{\partial}{\partial u_i} \right) \tag{2}$$

can be rewritten in terms of functions $f_i(u_i)$ defined by

$$\begin{aligned} &\frac{1}{h_1 h_2 h_3} \frac{\partial}{\partial u_i} \left(\frac{h_1 h_2 h_3}{h_i^2} \frac{\partial}{\partial u_i} \right) \\ &= \frac{g(u_{i+1}, u_{i+2})}{h_1 h_2 h_3} \frac{\partial}{\partial u_i} \left[f_i(u_i) \frac{\partial}{\partial u_i} \right] \\ &= \frac{1}{h_i^2 f_i} \frac{\partial}{\partial u_i} \left(f_i \frac{\partial}{\partial u_i} \right) \end{aligned} \tag{3}$$

such that S can be written

$$S = \frac{h_1 h_2 h_3}{f_1(u_1) f_2(u_2) f_3(u_3)}. \tag{4}$$

When this is true, the separated equations are OF THE FORM

$$\frac{1}{f_n} \frac{\partial}{\partial u_n} \left(f_n \frac{\partial X_n}{\partial u_n} \right) + (k_1^2 \Phi_{n1} + k_2^2 \Phi_{n2} + k_3^2 \Phi_{n3}) X_n = 0 \tag{5}$$

The Φ_{ij}s obey the minor equations

$$M_1 = \Phi_{22}\Phi_{33} - \Phi_{23}\Phi_{32} = \frac{S}{h_1^2} \tag{6}$$

$$M_2 = \Phi_{13}\Phi_{32} - \Phi_{12}\Phi_{33} = \frac{S}{h_2^2} \tag{7}$$

$$M_3 = \Phi_{12}\Phi_{23} - \Phi_{13}\Phi_{22} = \frac{S}{h_3^2}. \tag{8}$$

which are equivalent to

$$M_1\Phi_{11} + M_2\Phi_{21} + M_3\Phi_{31} = S \tag{9}$$

$$M_1\Phi_{12} + M_2\Phi_{22} + M_3\Phi_{32} = 0 \tag{10}$$

$$M_1\Phi_{13} + M_2\Phi_{23} + M_3\Phi_{33} = 0 \tag{11}$$

(Morse and Feshbach 1953, p. 509). This gives a total of four equations in nine unknowns. Morse and Feshbach (1953, pp. 655–66) give not only the Stäckel determinants for common coordinate systems, but also the elements of the determinant (although it is not clear how these are derived).

Staircase Function

A function composed of a set of equally spaced jumps of equal length, such as the CEILING FUNCTION $f(x) = \lceil x \rceil$, FLOOR FUNCTION $f(x) = \lfloor x \rfloor$, or NEAREST INTEGER FUNCTION $f(x) = [x]$.

See also CEILING FUNCTION, FLOOR FUNCTION, NEAREST INTEGER FUNCTION, SAWTOOTH WAVE

References

Spanier, J. and Oldham, K. B. *An Atlas of Functions.* Washington, DC: Hemisphere, p. 74, 1987.

Staircase Polygon

Define the minimal bounding rectangle as the smallest rectangle containing a given lattice polygon. If the perimeter of the lattice polygon is equal to that of its minimal bounding rectangle, it is said to be convex. (Note that a "convex" lattice polygon is not necessarily convex in the usual sense of the word.) A staircase polygon is then defined as a convex polygon which contains two opposite corners of its bounding rectangle (Bousquet-Mélou *et al.* 1999).

The area generating function $H_m(y, q)$ that counts polygons of width m for staircase polygons of width 4 is given by

$$H_4(q) = \frac{q^4(1 + 2q + 4q^2 + 6q^3 + 7q^4 + 6q^5 + 4q^6 + 2q^7 + q^8)}{(1-q)^2(1-q^2)^2(1-q^3)^2(1-q^4)}. \tag{1}$$

which satisfies

$$H_4(1/q) = -H_4(q)$$

(Bousquet-Mélou 1992, Bousquet-Mélou *et al.* 1999). The anisotropic area and perimeter generating function $G(x, y, q)$ and partial generating functions $H_m(y, q)$, connected by

$$G(x, y, q) = \sum_{m \geq 1} H_m(y, q) x^m.$$

satisfy the self-reciprocity and inversion relations

$$H_m(1/y, 1/q) = -y^{m-1} H_m(y, q)$$

for $m \geq 2$ and

$$G(x, y, q) + yG(x/y, 1/y, 1/q) = -x$$

(Bousquet-Mélou *et al.* 1999).

The anisotropic area and perimeter generating function $G(x, y, q)$ of staircase polygon with a staircase hole satisfies an inversion relation OF THE FORM

$$G(x, y, q) + y^2 G(x/y, 1/y, 1/q)$$

(Bousquet-Mélou *et al.* 1999).

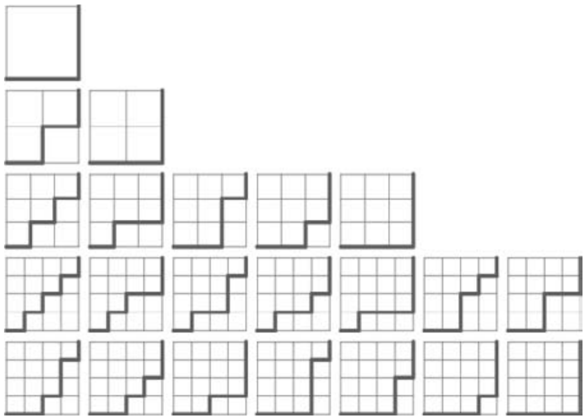
Staircase Walk



The numbers of staircase walks on an $m \times n$ grid are given by

$$\binom{m+n-2}{m-1} = \frac{(m+n-2)!}{(m-1)!(n-1)!} \tag{1}$$

(Vilenkin 1971, Mohanty 1979, Narayana 1979, Finch). The first few values for $m = n = 1, 2, ...,$ are 1, 2, 6, 20, 70, 252, ... (Sloane's A000984), which are

the CENTRAL BINOMIAL COEFFICIENTS.

The number of staircase walks on an $n \times n$ grid which remain below the diagonal is given by the CATALAN NUMBER

$$C_{n-1} = \frac{1}{n+1}\binom{2n}{n}.$$

i.e., 1, 2, 5, 14, 42, 132, ... (Sloane's A000108).

Stamp Folding

The number of ways of folding a strip of stamps has several possible variants. Considering only positions of the hinges for unlabeled stamps without regard to orientation of the stamps, the number of foldings is denoted $U(n)$. If the stamps are labeled and orientation is taken into account, the number of foldings is denoted $N(n)$. Finally, the number of symmetric foldings is denoted $S(n)$. The following table summarizes these values for the first n.

n	$S(n)$	$U(n)$	$N(n)$
Sloane	Sloane's A001010	Sloane's A001011	Sloane's A000136
1	1	1	1
2	2	1	2
3	2	2	6
4	4	5	16
5	6	14	50
6	8	38	144
7	18	120	462
8	20	353	1392
9	56	1148	4536

Stamp Problem

POSTAGE STAMP PROBLEM

Standard Deviation

The standard deviation stdv(x) is defined as the SQUARE ROOT of the VARIANCE σ^2,

$$\mathrm{stdv}(x) = \sigma = \sqrt{\langle x^2 \rangle - \langle x \rangle^2} = \sqrt{\mu_2' - \mu^2}. \tag{1}$$

where $\mu = \bar{x} = \langle x \rangle$ is the MEAN, $\mu_2' = \langle x^2 \rangle$ is the second RAW MOMENT, and $\langle f(x) \rangle$ denotes an EXPECTATION VALUE. The variance σ^2 is therefore equal to the second CENTRAL MOMENT (i.e., moment about the MEAN),

$$\sigma^2 = \mu_2. \tag{2}$$

The variate value producing a CONFIDENCE INTERVAL CI is often denoted x_{CI}, and

$$x_{\mathrm{CI}} = \sqrt{2}\,\mathrm{erf}^{-1}(\mathrm{CI}). \tag{3}$$

The following table lists the CONFIDENCE INTERVALS

corresponding to the first few multiples of the standard deviation.

range	CI
σ	0.6826895
2σ	0.9544997
3σ	0.9973002
4σ	0.9999366
5σ	0.9999994

To find the standard deviation range corresponding to a given CONFIDENCE INTERVAL, solve (2) for n, giving

$$n = \sqrt{2}\,\operatorname{erf}^{-1}(\mathrm{CI}). \tag{4}$$

CI	range
0.800	$\pm 1.28155\sigma$
0.900	$\pm 1.64485\sigma$
0.950	$\pm 1.95996\sigma$
0.990	$\pm 2.57583\sigma$
0.995	$\pm 2.80703\sigma$
0.999	$\pm 3.29053\sigma$

The square root of the SAMPLE VARIANCE is the "sample" standard deviation,

$$s_N = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(x_i - \bar{x})^2}. \tag{5}$$

It is a BIASED ESTIMATOR of the population standard deviation. An unbiased ESTIMATOR is given by

$$s_{N-1} = \sqrt{\frac{1}{N-1}\sum_{i=1}^{N}(x_i - \bar{x})^2}. \tag{6}$$

Physical scientists often use the term ROOT-MEAN-SQUARE as a synonym for standard deviation when they refer to the SQUARE ROOT of the mean squared deviation of a signal from a given baseline or fit.

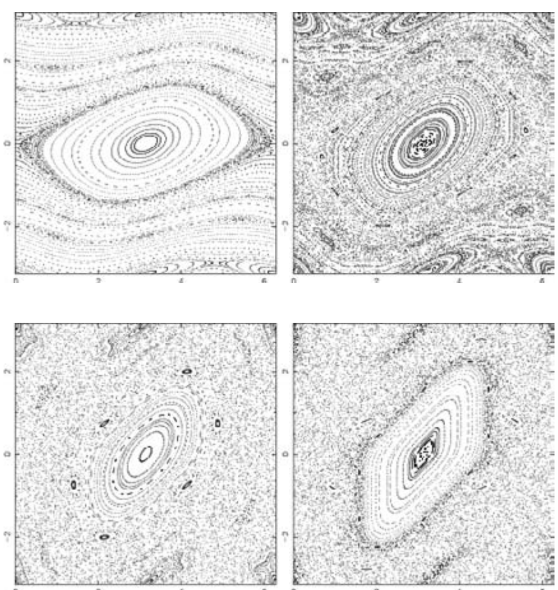
See also CONFIDENCE INTERVAL, MEAN, MOMENT, ROOT-MEAN-SQUARE, SAMPLE VARIANCE, STANDARD ERROR, VARIANCE

References

Kenney, J. F. and Keeping, E. S. "The Standard Deviation" and "Calculation of the Standard Deviation." §6.5–.6 in *Mathematics of Statistics, Pt. 1, 3rd ed.* Princeton, NJ: Van Nostrand, pp. 77–0, 1962.

Standard Error

The square root of the ESTIMATED VARIANCE of a quantity,



$$\text{standard error} = \sqrt{\widehat{\operatorname{var}}\,x}.$$

However, the standard error is sometimes also used to mean

$$\operatorname{var}(\bar{x}) = \sum_{i=1}^{n}\left(\frac{1}{n}\right)^2 \sigma_i^2 = \sum_{i=1}^{n}\left(\frac{1}{n}\right)^2 \sigma^2 = \frac{\sigma^2}{n}.$$

See also ESTIMATOR, STANDARD DEVIATION, VARIANCE

Standard Map

A 2-D MAP also called the Taylor-Greene-Chirikov map in some of the older literature and defined by

$$I_{n+1} = I_n + K \sin\theta_n \tag{1}$$

$$\theta_{n+1} = \theta_n = I_{n+1} + \theta_n + K \sin\theta_n, \tag{2}$$

where I and θ are computed mod 2π and K is a POSITIVE constant.

The standard map can be implemented in *Mathematica* as

```
StandardMap[k_, its_:100, cnt_:50] := Mod-
ule[{},
  f[{t_, i_}] := Mod[{i + t + k Sin[t], i + k
Sin[t]}, 2Pi];
  Graphics[{
    PointSize[.01],
    Table[
      Point /@ NestList[f, #, its] & [
```

```
        Table[Random[Real,  {0,  2Pi}],  {2}]],
{cnt}]
  },
  AspectRatio->Automatic] ]
```

An analytic estimate of the width of the CHAOTIC zone (Chirikov 1979) finds

$$\delta I = Be^{-AK^{-1/2}}. \tag{3}$$

Numerical experiments give $A \approx 5.26$ and $B \approx 240$. The value of K at which global CHAOS occurs has been bounded by various authors. GREENE'S METHOD is the most accurate method so far devised.

Author	Bound	Fraction	Decimal
Hermann	$>$	$\frac{1}{34}$	0.029411764
Italians	$>$	-	0.65
Greene	$\approx$	-	0.971635406
MacKay and Pearson	$<$	$\frac{63}{64}$	0.984375000
Mather	$<$	$\frac{4}{3}$	1.333333333

FIXED POINTS are found by requiring that

$$I_{n+1} = I_n \tag{4}$$

$$\theta_{n+1} = \theta_n. \tag{5}$$

The first gives $K \sin\theta_n = 0$, so $\sin\theta_n = 0$ and

$$\theta_n = 0,\ \pi. \tag{6}$$

The second requirement gives

$$I_n + K \sin\theta_n = I_n = 0. \tag{7}$$

The FIXED POINTS are therefore $(I, \theta) = (0, 0)$ and $(0, \pi)$. In order to perform a LINEAR STABILITY analysis, take differentials of the variables

$$dI_{n+1} = dI_n + K \cos\theta_n\, d\theta_n \tag{8}$$

$$d\theta_{n+1} = dI_n + (1 + K\cos\theta_n)\, d\theta_n. \tag{9}$$

In MATRIX form,

$$\begin{bmatrix} \delta I_{n+1} \\ \delta\theta_{n+1} \end{bmatrix} = \begin{bmatrix} 1 & K\cos\theta_n \\ 1 & 1+K\cos\theta_n \end{bmatrix} \begin{bmatrix} \delta I_n \\ \delta\theta_n \end{bmatrix}. \tag{10}$$

The EIGENVALUES are found by solving the CHARACTERISTIC EQUATION

$$\begin{bmatrix} 1-\lambda & K\cos\theta_n \\ 1 & 1+K\cos\theta_n - \lambda \end{bmatrix} = 0. \tag{11}$$

so

$$\lambda^2 - \lambda(K\cos\theta_n + 2) + 1 = 0 \tag{12}$$

$$\lambda_\pm = \tfrac{1}{2}\left[K\cos\theta_n + 2 \pm \sqrt{(K\cos\theta_n + 2)^2 - 4}\right]. \tag{13}$$

For the FIXED POINT $(0, \pi)$,

$$\lambda_\pm^{(0,\ \pi)} = \tfrac{1}{2}\left[2 - K \pm \sqrt{(2-K)^2 - 4}\right]$$

$$= \tfrac{1}{2}\left(2 - K \pm \sqrt{K^2 - 4K}\right). \tag{14}$$

The FIXED POINT will be stable if $|\Re(\lambda^{(0,\ \pi)})| < 2$. Here, that means

$$\tfrac{1}{2}|2-K| < 1 \tag{15}$$

$$|2-K| < 2 \tag{16}$$

$$-2 < 2-K < 2 \tag{17}$$

$$-4 < -K < 0 \tag{18}$$

so $K \in [0,\ 4)$. For the FIXED POINT $(0, 0)$, the EIGENVALUES are

$$\lambda_\pm^{(0,\ 0)} = \tfrac{1}{2}\left[2 + K \pm \sqrt{(K+2)^2 - 4}\right]$$

$$\tfrac{1}{2}\left(2 + K \pm \sqrt{K^2 + 4K}\right). \tag{19}$$

If the map is unstable for the larger EIGENVALUE, it is unstable. Therefore, examine $\lambda_+^{(0,\ 0)}$. We have

$$\frac{1}{2}\left|2 + K + \sqrt{K^2 + 4K}\right| < 1. \tag{20}$$

so

$$-2 < 2 + K + \sqrt{K^2 + 4K} < 2 \tag{21}$$

$$-4 - K < \sqrt{K^2 + 4K} < -K. \tag{22}$$

But $K > 0$, so the second part of the inequality cannot be true. Therefore, the map is unstable at the FIXED POINT $(0, 0)$.

Standard Tableau

YOUNG TABLEAU

Standard Tori

One of the three classes of TORI illustrated above and given by the PARAMETRIC EQUATIONS

$$x = (c + a\cos v)\cos u \tag{1}$$

$$y = (c + a\cos v)\sin u \tag{2}$$

$$z = a\sin v. \tag{3}$$

The three different classes of standard tori arise from the three possible relative sizes of a and c. $c > a$ corresponds to the RING TORUS shown above, $c = a$ corresponds to a HORN TORUS which touches itself at the point (0, 0, 0), and $c < a$ corresponds to a self-intersecting SPINDLE TORUS (Pinkall 1986). If no specification is made, "torus" is taken to mean RING TORUS.

The standard tori and their inversions are CYCLIDES.

Stanley's Theorem

The total number of 1s that occur among all unordered PARTITIONS of a POSITIVE INTEGER is equal to the sum of the numbers of distinct members of those PARTITIONS. For example, the partitions of 5 are $\{5\}$, $\{1, 1\}$, $\{3, 2\}$, $\{3, 1, 1\}$, $\{2, 2, 1\}$, $\{2, 1, 1, 1\}$, $\{1, 1, 1, 1, 1\}$. There are a total of $0+1+0+2+1+3+5=12$ 1s in this list, which is equal to the sums of the numbers of unique terms in each partition: $1+2+2+2+2+2+1=12$.

The numbers of 1s occurring in all partitions of $n=1$, 2, 3, ... are 1, 2, 4, 7, 12, 19, 30, 45, 67, ... (Sloane's A000070).

Stanley-Wilf Conjecture

Stanley and Wilf conjectured (Bona 1997, Arratia 1999), that for every PERMUTATION PATTERN σ, there is a constant $c(\sigma)<\infty$ such that for all n,

$$F(n,\ \sigma)\leq[c(\sigma)]^n. \quad (1)$$

A related conjecture stated that for every σ, the limit

$$\lim_{n\to\infty}[F(n,\ \sigma)]^{1/n} \quad (2)$$

exists and is finite. Arratia (1999) showed that these two conjectures are equivalent.

Star

The word "star" is used to voice an asterisk when appearing in a mathematical expression. For example, a^* is voiced "a-star". The "star" is used to denote the ADJOINT a^*, or sometimes the COMPLEX CONJUGATE.

In common usage, a star is a STAR POLYGON or STAR FIGURE (i.e., regular convex polygon or polygon compound) such as the PENTAGRAM or HEXAGRAM

In formal geometry, a star is a set of $2n$ VECTORS $\pm a_1$, ..., $\pm a_n$ which form a fixed center in EUCLIDEAN 3-SPACE.

In ALGEBRAIC TOPOLOGY, if v is a vertex of a SIMPLICIAL COMPLEX K, then the star of v in K, denoted St v or $\mathrm{St}(v, K)$, is the union of the interiors of those SIMPLICES of K that have v as a vertex (Munkres 1993, p. 11).

Star Graph

The n-star graph is a TREE on $n+1$ nodes with one node having VERTEX DEGREE n and the others having VERTEX DEGREE 1. Star graphs S_n are always GRACEFUL. Star graphs can be constructed using `Star[n]` in the *Mathematica* add-on package `DiscreteMath`-` `Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

The COMPLETE BIPARTITE GRAPH $K_{1,\,n-1}$ is the STAR GRAPH S_n (Skiena 1990, p. 146). The CHROMATIC POLYNOMIAL of S_n is given by

$$\pi_{s_n}(z) = z(z-1)^{n-1}.$$

and the CHROMATIC NUMBER is 1 for $n = 1$, and $\chi(S_n) = 2$ otherwise.

Star Number

The number of cells in a generalized Chinese checkers board (or "centered" HEXAGRAM).

$$S_n = 6n(n+1) + 1 = S_{n-1} + 12(n-1). \tag{1}$$

The first few are 1, 13, 37, 73, 121, ... (Sloane's A003154). Every star number has DIGITAL ROOT 1 or 4, and the final digits must be one of: 01, 21, 41, 61, 81, 13, 33, 53, 73, 93, or 37.

The first TRIANGULAR star numbers are 1, 253, 49141, 9533161, ... (Sloane's A006060), and can be computed using

$$TS_n = \frac{3\left[(7+4\sqrt{3})^{2n-1} + (7-4\sqrt{3})^{2n-1}\right] - 10}{32} \tag{2}$$

$$= 194TS_{n-1} + 60 - TS_{n-2}. \tag{3}$$

The first few SQUARE star numbers are 1, 121, 11881, 1164241, 114083761, ... (Sloane's A006061). SQUARE star numbers are obtained by solving the DIOPHANTINE EQUATION

$$2x^2 + 1 = 3y^2 \tag{4}$$

and can be computed using

$$SS_n = \frac{\left[(5+2\sqrt{6})^n(\sqrt{6}-2) - (5-2\sqrt{6})^n(\sqrt{6}+2)\right]^2}{4}. \tag{5}$$

Star of David

HEXAGRAM

Star of David Theorem

As originally stated by Gould (1972),

$$\operatorname{GCD}\left\{\binom{n-1}{k}, \binom{n}{k-1}, \binom{n+1}{k+1}\right\} = \operatorname{GCD}\left\{\binom{n-1}{k-1}, \binom{n}{k+1}, \binom{n+1}{k}\right\}, \quad (1)$$

where GCD is the GREATEST COMMON DIVISOR and $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. This was subsequently extended by D. Singmaster to

$$\operatorname{GCD}\left\{\binom{n-1}{k}, \binom{n}{k-1}, \binom{n+1}{k+1}\right\} = \operatorname{GCD}\left\{\binom{n-1}{k-1}, \binom{n}{k+1}, \binom{n+1}{k}\right\} = \operatorname{GCD}\left\{\binom{n-1}{k-2}, \binom{n-1}{k-1}, \binom{n-1}{k}, \binom{n-1}{k+1}\right\} \quad (2)$$

(Sato 1975), and generalized by Sato (1975) to

$$\operatorname{GCD}\left\{\binom{n}{k+2}, \binom{n-1}{k}, \binom{n-2}{k-2}, \binom{n}{k-1}, \binom{n+2}{k} \binom{n+1}{k+1}\right\} = \operatorname{GCD}\left\{\binom{n-2}{k}, \binom{n-1}{k-1}, \binom{n}{k-2}, \binom{n+1}{k}, \binom{n+2}{k+2} \binom{n}{k+1}\right\} \quad (3)$$

An even larger generalization was obtained by Hitotumatu and Sato (1975), who defined

$$M_p = \left\{\binom{n-p+1}{k-2p+j+1} \middle| j = 1,\ 2,\ \ldots,\ 3p-2\right\}, \quad (p \geq 1) \quad (4)$$

$$A_p = \left\{\binom{n-p+j}{k+p-1} \middle| j = 1,\ 2,\ \ldots,\ 3p-2\right\} \quad (p \geq 1) \quad (5)$$

$$R_p = \left\{\binom{n-p+j}{k-2p+j-1} \middle| j = 1,\ 2,\ \ldots,\ 3p-2\right\} \quad (p \geq 1) \quad (6)$$

$$\Delta_p = \left\{\binom{n-p+2t+1}{k-p+t+1}, \binom{n+p-t-1}{k+t}, \binom{n-t}{k+p-2t-1} \middle| t = 1,\ 2,\ \ldots,\ p-1\right\} \quad (p \geq 2) \quad (7)$$

$$\nabla_p = \left\{\binom{n-t}{k-p+t+1}, \binom{n-p+2t+1}{k+t}, \binom{n+p-t-1}{k+p-2t-1} \middle| t = 1,\ 2,\ \ldots,\ p-1\right\} \quad (p \geq 2) \quad (8)$$

$$U_p = \bigcup_{r=1}^{p} M_r \quad (9)$$

$$V_p = \bigcup_{r=1}^{p} A_r \quad (10)$$

$$W_p = \bigcup_{r=1}^{p} R_r \quad (11)$$

$$D_p = \bigcup_{r=1}^{p} \Delta_r \quad (12)$$

$$N_p = \bigcup_{r=1}^{p} \nabla_r \quad (13)$$

$$B_p = M_p \cup A_p \cup R_p \quad (14)$$

$$S_p = \bigcup_{r=1}^{p} B_r \quad (15)$$

with

$$\Delta_1 = \nabla_1 = \binom{n}{k}. \quad (16)$$

and showed that each of the twelve BINOMIAL COEFFICIENTS M_p, A_p, R_p, Δ_p, ∇_p, U_p, V_p, W_p, ∇_p, N_p, B_p, and S_p has equal GREATEST COMMON DIVISOR.

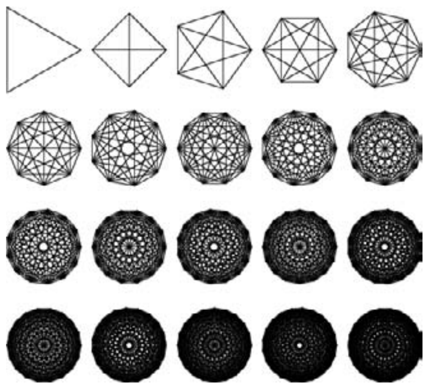
Savio, D. Y. and Suryanaroyan, E. R. "Chebyshev Polynomials and Regular Polygons." *Amer. Math. Monthly* **100**, 657–61, 1993.

Star Polygon

A star polygon $\{p/q\}$, with p, q POSITIVE INTEGERS, is a figure formed by connecting with straight lines every qth point out of p regularly spaced points lying on a CIRCUMFERENCE. The number q is called the DENSITY of the star polygon. Without loss of generality, take $q < p/2$. The star polygons were first systematically studied by Thomas Bradwardine.

The usual definition (Coxeter 1969) requires p and q to be RELATIVELY PRIME. However, the star polygon can also be generalized to the STAR FIGURE (or "improper" star polygon) when p and q share a common divisor (Savio and Suryanaroyan 1993). For such a figure, if all points are not connected after the first pass, i.e., if $(p, q) \neq 1$, then start with the first unconnected point and repeat the procedure. Repeat until all points are connected. For $(p, q) \neq 1$, the $\{p/q\}$ symbol can be factored as

$$\left\{\frac{p}{q}\right\} = n\left\{\frac{p'}{q'}\right\}, \tag{1}$$



where

$$p' = \frac{p}{n} \tag{2}$$

$$q' = \frac{q}{n}, \tag{3}$$

to give n $\{p'/q'\}$ figures, each rotated by $2\pi/p$ radians, or $360°/p$.

If $q = 1$, a REGULAR POLYGON $\{p\}$ is obtained. Special cases of $\{p/q\}$ include $\{5/2\}$ (the PENTAGRAM), $\{6/2\}$ (the HEXAGRAM, or STAR OF DAVID), $\{8/2\}$ (the STAR OF LAKSHMI), $\{8/3\}$ (the OCTAGRAM), $\{10/3\}$ (the DECAGRAM), and $\{12/5\}$ (the DODECAGRAM).

Superposing all distinct star polygons $\{p/q\}$ for a given p gives beautiful patterns such as those illustrated above. These figures can also be obtained by wrapping thread around p nails spaced equally around the circumference of a circle (Steinhaus 1983, pp. 259–60).

State Space

The measurable space $(S', \mathbb{S}')$ into which a random variable from a probability space is a measurable function.

See also Probability Space, Random Variable

Stationary Point

A point x_0 at which the derivative of a function $f(x)$ vanishes,

$$f'(x_0) = 0.$$

A stationary point may be a minimum, maximum, or inflection point.

See also Critical Point, Derivative, Extremum, First Derivative Test, Inflection Point, Maximum, Minimum, Second Derivative Test

Stationary Tangent

Inflection Point

Stationary Value

The value at a stationary point.

Statistic

A quantity (such as a median, quartile deviation, etc.), which is calculated from observed data.

Statistical Distribution

The distribution of a variable is a description of the relative numbers of times each possible outcome will occur in a number of trials. The function describing the distribution is called the probability function, and the function describing the cumulative probability that a given value *or any value smaller than it* will occur is called the distribution function.

Formally, a distribution can be defined as a normalized measure, and the distribution of a random variable x is the measure P_x on $\mathbb{S}'$ defined by setting

$$P_x(A') = P\{s \in S : x(s) \in A'\},$$

where $(S, \mathbb{S}, P)$ is a PROBABILITY SPACE, $(S, \mathbb{S})$ is a MEASURABLE SPACE, and P a MEASURE on $\mathbb{S}$ with $P(S) = 1$. If the MEASURE is a RADON MEASURE (which is usually the case), then the statistical distribution is a DISTRIBUTION in the sense of a generalized function.

Statistical Index

INDEX NUMBER

Statistical Test

A test used to determine the statistical SIGNIFICANCE of an observation. Two main types of error can occur:

1. A TYPE I ERROR occurs when a false negative result is obtained in terms of the NULL HYPOTHESIS by obtaining a *false positive measurement.*
2. A TYPE II ERROR occurs when a false positive result is obtained in terms of the NULL HYPOTHESIS by obtaining a *false negative measurement.*

The probability that a statistical test will be positive for a true statistic is sometimes called the test's SENSITIVITY, and the probability that a test will be negative for a negative statistic is sometimes called the SPECIFICITY. The following table summarizes the names given to the various combinations of the actual state of affairs and observed test results.

result	name
true positive result	SENSITIVITY
false negative result	1-SENSITIVITY
true negative result	SPECIFICITY
false positive result	1-SPECIFICITY

Multiple-comparison corrections to statistical tests are used when several statistical tests are being performed simultaneously. For example, let's suppose you were measuring leg length in eight different lizard species and wanted to see whether the MEANS of any pair were different. Now, there are $8!/2!6! = 28$ pairwise comparisons possible, so even if all of the *population* means are equal, it's quite likely that at least one pair of sample means would differ significantly at the 5% level. An ALPHA VALUE of 0.05 is therefore appropriate for each individual comparison, but not for the set of *all* comparisons.

In order to avoid a lot of spurious positives, the ALPHA VALUE therefore needs to be lowered to account for the number of comparisons being performed. This is a correction for multiple comparisons. There are *many* different ways to do this. The simplest, and the most conservative, is the BONFERRONI CORRECTION. In practice, more people are more willing to accept false positives (false rejection of NULL HYPOTHESIS) than false negatives (false acceptance of NULL HYPOTHESIS), so less conservative comparisons are usually used.

Statistics

The mathematical study of the LIKELIHOOD and PROBABILITY of events occurring based on known information and inferred by taking a limited number of samples. Statistics plays an extremely important role in many aspects of economics and science, allowing educated guesses to be made with a minimum of expensive or difficult-to-obtain data.

Staudt-Clausen Theorem

VON STAUDT-CLAUSEN THEOREM

Steenrod Algebra

The Steenrod algebra has to do with the COHOMOLOGY operations in singular COHOMOLOGY with INTEGER mod 2 COEFFICIENTS. For every $n \in \mathbb{Z}$ and $i \in \{0, 1, 2, 3, \ldots\}$ there are natural transformations of FUNCTORS

$$Sq^i : H^n(\bullet;\ \mathbb{Z}_2) \to H^{n+i}(\bullet;\ \mathbb{Z}_2)$$

satisfying:

1. $Sq^i = 0$ for $i > n$.
2. $Sq^n(x) = x \smile x$ for all $x \in H^n(X, A;\ \mathbb{Z}_2)$ and all pairs (X, A).
3. $Sq^0 = id_{H^n(\bullet;\mathbb{Z}_2)}$.
4. The Sq^i maps commute with the coboundary maps in the long exact sequence of a pair. In other words,

$$Sq^i : H^*(\bullet;\ \mathbb{Z}_2) \to H^{*+i}(\bullet;\ \mathbb{Z}_2)$$

is a degree i transformation of cohomology theories.

5. (CARTAN RELATION)

$$Sq^i(x \smile y) = \sum_{j+k=i} Sq^j(x) \smile Sq^k(y).$$

6. (ADEM RELATIONS) For $i < 2j$,

$$Sq^i \circ Sq^j(x) = \sum_{k=0}^{\lfloor i \rfloor} \binom{j-k-1}{i-2k} Sq^{i+j-k} \circ Sq^k(x).$$

7. $Sq^i \circ \Sigma = \Sigma \circ Sq^i$ where Σ is the cohomology suspension isomorphism.

The existence of these cohomology operations endows the cohomology ring with the structure of a MODULE over the Steenrod algebra $\mathscr{A}$, defined to be $T\left(F_{\mathbb{Z}_2}\{Sq^i : i \in \{0, 1, 2, 3, \ldots\}\}\right)/R$, where $F_{\mathbb{Z}_2}(\bullet)$ is the free module functor that takes any set and sends it to the free $\mathbb{Z}_2$ module over that set. We think of $F_{\mathbb{Z}_2}\{Sq^i : i \in \{0, 1, 2, \ldots\}\}$ as being a graded $\mathbb{Z}_2$ module, where the i-th gradation is given by $\mathbb{Z}_2 \cdot Sq^i$. This makes the tensor algebra $T\left(F_{\mathbb{Z}_2}\{Sq^i : i \in \{0, 1, 2, 3, \ldots\}\}\right)$ into a GRADED ALGEBRA over $\mathbb{Z}_2$. R is the IDEAL generated by the elements $Sq^i Sq^j + \Sigma_{k=0}^{\lfloor i \rfloor} \binom{j-k-1}{i-2k} Sq^{i+j-k} Sq^k$ and $1 + Sq^0$ for $0 < i < 2j$. This makes $\mathscr{A}$ into a graded $\mathbb{Z}_2$ algebra.

By the definition of the Steenrod algebra, for any SPACE (X, A), $H^*(X, A; \mathbb{Z}_2)$ is a MODULE over the Steenrod algebra $\mathscr{A}$, with multiplication induced by $Sq^i \cdot x \equiv Sq^i(x)$. With the above definitions, cohomology with COEFFICIENTS in the RING $\mathbb{Z}_2$, $H^*(\bullet; \mathbb{Z}_2)$ is a FUNCTOR from the category of pairs of TOPOLOGICAL SPACES to graded modules over $\mathscr{A}$.

Steenrod-Eilenberg Axioms

EILENBERG-STEENROD AXIOMS

Steenrod's Realization Problem

When can homology classes be realized as the image of fundamental classes of MANIFOLDS? The answer is known, and singular BORDISM GROUPS provide insight into this problem.

See also BORDISM GROUP, MANIFOLD

Steepest Descent Method

An ALGORITHM for finding the nearest LOCAL MINIMUM of a function which presupposes that the GRADIENT of the function can be computed. The steepest descent method, also called the gradient descent method, starts at a point $\mathbf{P}_0$ and, as many times as needed, moves from $\mathbf{P}_i$ to $\mathbf{P}_{i+1}$ by minimizing along the line extending from $\mathbf{P}_i$ in the direction of $-\nabla f(\mathbf{P}_i)$, the local downhill GRADIENT.

This method has the severe drawback of requiring a great many iterations for functions which have long, narrow valley structures. In such cases, a CONJUGATE GRADIENT METHOD is preferable.

Steffensen Sequence

A sequence

$$s_n^{(\lambda)}(x) = [h(t)]^\lambda s_n(x),$$

where $s_n(x)$ is a SHEFFER SEQUENCE, $h(t)$ is invertible, and λ ranges over the real numbers. If $s_n(x)$ is an associated SHEFFER SEQUENCE, then $s_n^{(\lambda)}$ is called a CROSS SEQUENCE. If $s_n(x) = x^n$, then

$$s_n^{(\lambda)}(x) = [h(t)]^\lambda x^n$$

is called an APPELL CROSS SEQUENCE.

An example is the LAGUERRE POLYNOMIAL.

Steffensen's Inequality

Let $f(x)$ be a NONNEGATIVE and monotonic decreasing function in $[a, b]$ and $g(x)$ such that $0 \leq g(x) \leq 1$ in $[a, b]$, then

$$\int_{b-k}^{b} f(x)\,dx \leq \int_a^b f(x)g(x)\,dx \leq \int_a^{a+k} f(x)\,dx.$$

where

$$k = \int_a^b g(x)\, dx.$$

Steiner Chain

Given two nonconcentric CIRCLES with one interior to the other, if small TANGENT CIRCLES can be inscribed around the region between the two CIRCLES such that the final CIRCLE is TANGENT to the first, the CIRCLES form a Steiner chain.

Steiner chain with n = 7

The simplest way to construct a Steiner chain is to perform an INVERSION on a symmetrical arrangement on n circles packed between a central circle of radius b and an outer concentric circle of radius a (Wells 1991). In this arrangement,

$$\sin\left(\frac{\pi}{n}\right) = \frac{a-b}{a+b}, \tag{1}$$

so the ratio of the radii for the small and large circles is

$$\frac{b}{a} = \frac{1-\sin\left(\frac{\pi}{n}\right)}{1+\sin\left(\frac{\pi}{n}\right)}. \tag{2}$$

In addition, the radii of the circles in the ring are

$$c = \tfrac{1}{2}(a-b), \tag{3}$$

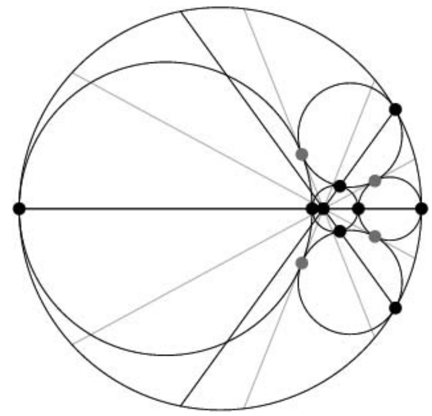
and their centers are located at a distance

$$r = b + c = \tfrac{1}{2}(a+b) \tag{4}$$

from the origin.

To transform the symmetrical arrangement into a Steiner chain, take an INVERSION CENTER which is a distance d from the center of the symmetrical figure. Then the radii a' and b' of the outer and center circles become

$$a' = \left|\frac{a}{d^2 - a^2}\right| = \frac{a}{a^2 - d^2} \tag{5}$$



$$b' = \left|\frac{b}{d^2 - b^2}\right| = \frac{b}{b^2 - d^2}, \tag{6}$$

respectively. Equivalently, a Steiner chain results whenever the INVERSIVE DISTANCE between the two original circles is given by

$$\delta = 2\ln\left[\sec\left(\frac{\pi}{n}\right) + \tan\left(\frac{\pi}{n}\right)\right] \tag{7}$$

$$= 2\ln\left[\tan\left(\frac{\pi}{4} + \frac{\pi}{2n}\right)\right] \tag{8}$$

(Coxeter and Greitzer 1967).

The centers of the circles in a Steiner chain lie on an ELLIPSE (Ogilvy 1990, p. 57). The lines of tangency passing through the contact points of neighboring circles in the chain are concurrent in a point. Furthermore, this is the same point at which the lines through the contact points of the inner and outer circles also concur (Wells 1991, p. 245).

STEINER'S PORISM states that if a Steiner chain is formed from one starting circle, then a Steiner chain is also formed from any other starting circle. A Steiner chain may also close after several loops around the central circle, in which case a Steiner chain will also be formed after the same number of loops from any starting point.

Steiner Construction

A construction done using only a STRAIGHTEDGE. The PONCELET-STEINER THEOREM proves that all constructions possible using a COMPASS and STRAIGHTEDGE are possible using a STRAIGHTEDGE alone, as long as a fixed CIRCLE and its center, two intersecting

CIRCLES without their centers, or three nonintersecting CIRCLES are drawn beforehand. For example, the centers of two intersecting circles can be found using a STRAIGHTEDGE alone (Steinhaus 1983, p. 42).

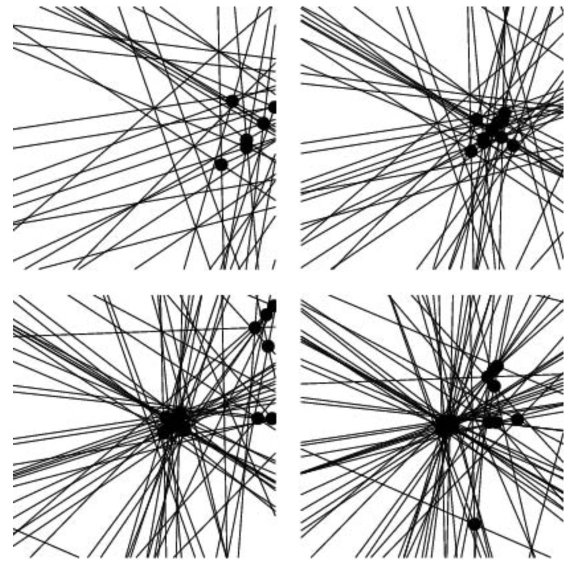
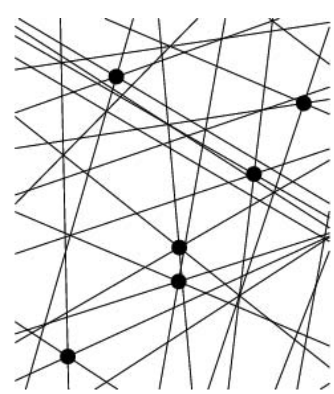
Steiner Points



There are two different types of points known as Steiner points.



The point S of CONCURRENCE of the three lines drawn through the VERTICES of a TRIANGLE PARALLEL to the corresponding sides of the first BROCARD TRIANGLE is called the Steiner point (Honsberger 1995). It lies on the CIRCUMCIRCLE opposite the TARRY POINT T and has TRIANGLE CENTER FUNCTION

$$\alpha = bc(a^2 - b^2)(a^2 - c^2).$$

The BRIANCHON POINT for KIEPERT'S PARABOLA is also called the Steiner point. The SYMMEDIAN POINT K is the Steiner point of the first BROCARD TRIANGLE (Honsberger 1995, pp. 120–21). The SIMSON LINE of the Steiner point is PARALLEL to the line OK, when O is the CIRCUMCENTER and K is the SYMMEDIAN POINT (Honsberger 1995, p. 121). The Steiner point of a TRIANGLE is the CENTROID of the system obtained by placing a mass equal to the magnitude of the exterior angle at each vertex (Honsberger 1995, p. 120).

If triplets of opposites sides on a CONIC SECTION in PASCAL'S THEOREM are extended for all permutations of VERTICES, 60 PASCAL LINES are produced. The 20 points of their three by three intersections are called Steiner points. STEINER'S THEOREM states that these points are generated by the hexagons 123456, 143652, and 163254 formed by interchanging the vertices at positions 2, 4, and 6 (where the numbers denote the order in which the vertices of the hexagon are taken). The configuration of PASCAL LINES for a general hexagon inscribed in a general ellipse are shown above, with Steiner points shown as filled circles. A blow-up of the region in the upper left figure is shown below, illustrating the concurrence of three Pascal lines at each Steiner point.

Each Steiner point lies together with three KIRKMAN POINTS on a total of 20 lines known as CAYLEY LINES. The Steiner points also lie four at a time on 15 PLÜCKER LINES (Wells 1991). There is a dual relationship between the 20 Steiner points and the 20 CAYLEY LINES.

Steiner Quadruple System

A Steiner quadruple system is a STEINER SYSTEM $S(t=3,\ k=4,\ v)$, where S is a v-set and B is a collection of k-sets of S such that every t-subset of S is contained in exactly one member of B. Barrau (1908) established the uniqueness of $S(3,\ 4,\ 8)$,

1	2	4	8	3	5	6	7
2	3	5	8	1	4	6	7
3	4	6	8	1	2	5	7
4	5	7	8	1	2	3	6
1	5	6	8	2	3	4	7
2	6	7	8	1	3	4	5
1	3	7	8	2	4	5	6

and $S(3,\ 4,\ 10)$

1	2	4	5	1	2	3	7	1	3	5	8
2	3	5	6	2	3	4	8	2	4	6	9
3	4	6	7	3	4	5	9	3	5	7	0
4	5	7	8	4	5	6	0	1	4	6	8
5	6	8	9	1	5	6	7	2	5	7	9
6	7	9	0	2	6	7	8	3	6	8	0
1	7	8	0	3	7	8	9	1	4	7	9
1	2	8	9	4	8	9	0	2	5	8	0
2	3	9	0	1	5	9	0	1	3	6	9
1	3	4	0	1	2	6	0	2	4	7	0

Fitting (1915) subsequently constructed the cyclic systems $S(3,\ 4,\ 26)$ and $S(3,\ 4,\ 34)$, and Bays and de Weck (1935) showed the existence of at least one $S(3,\ 4,\ 14)$. Hanani (1960) proved that a NECESSARY and SUFFICIENT condition for the existence of an $S(3,\ 4,\ v)$ is that $v\equiv 2$ or 4 (mod 6).

The number of nonisomorphic steiner quadruple systems of orders 8, 10, 14, and 16 are 1, 1, 4 (Mendelsohn and Hung 1972), and at least 31,021 (Lindner and Rosa 1976).

Steiner Set

Three sets of three LINES such that each line is incident with two from both other sets.

See also SOLOMON'S SEAL LINES, STEINER POINTS, STEINER TRIPLE SYSTEM

Steiner Surface

A projection of the VERONESE SURFACE into 3-D (which must contain singularities) is called a Steiner surface. A classification of Steiner surfaces allowing complex parameters and projective transformations was accomplished in the 19th century. The surfaces obtained by restricting to real parameters and transformations were classified into 10 types by Coffman *et al.* (1996). Examples of Steiner surfaces include the ROMAN SURFACE (Coffman type 1) and CROSS-CAP (type 3).

The Steiner surface of type 2 is given by the implicit equation

$$x^2y^2-x^2z^2+y^2z^2-xyz=0.$$

and can be transformed into the ROMAN SURFACE or CROSS-CAP by a complex projective change of coordinates (but not by a real transformation). It has two pinch points and three double lines and, unlike the ROMAN SURFACE or CROSS-CAP, is not compact in any affine neighborhood.

The Steiner surface of type 4 has the implicit equation

$$y^2-2xy^2-xz^2+x^2y^2+x^2z^2-z^4=0.$$

and two of the three double lines of surface 2 coincide

along a line where the two noncompact "components" are tangent.

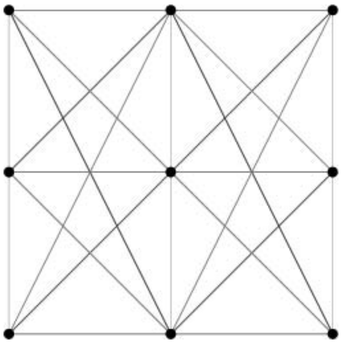
Steiner System

A Steiner system $S(t, k, v)$ is a set X of v points, and a collection of subsets of X of size k (called blocks), such that any t points of X are in exactly one of the blocks. The special case $t=2$ and $k=3$ corresponds to a so-called STEINER TRIPLE SYSTEM. For a PROJECTIVE PLANE, $v=n^2+n+1$, $k=n+1$, $t=2$, and the blocks are simply lines.



The number r of blocks containing a point in a $S(t, k, v)$ Steiner system is independent of the point. In fact,

$$r=\frac{\binom{v-1}{t-1}}{\binom{k-1}{t-1}},$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. The total number of blocks b is also determined and is given by

$$b=\frac{vr}{k}.$$

These numbers also satisfy $v \leq b$ and $k \leq r$.

The PERMUTATIONS of the points preserving the blocks of a Steiner system S is the AUTOMORPHISM GROUP of S. For example, consider Ω the set of 9 points in the 2-dimensional VECTOR SPACE over the FIELD over 3 elements. The blocks are the 12 lines of the form $\{a+tb\}=\{a, a+b, a+2b\}$, which have three elements each. The system is a $S(2, 3, 9)$ because any two points uniquely determine a line.

The AUTOMORPHISM GROUP of a Steiner system is the AFFINE GROUP which preserves the lines. For a vector space of dimension n over a field of q elements, this construction gives a Steiner system $S(2, q, q^d)$.

Several interesting groups arise as automorphism groups of Steiner systems. For example, the MATHIEU GROUPS are the AUTOMORPHISM GROUPS of Steiner systems, as summarized in the following table. These groups are unique up to ISOMORPHISM, and are not only SPORADIC SIMPLE GROUPS, but are also highly TRANSITIVE.

Mathieu group	Steiner system
M_{11}	$S(3, 4, 14)$
M_{12}	$S(5, 6, 12)$
M_{22}	$S(3, 6, 22)$
M_{23}	$S(4, 7, 23)$
M_{24}	$S(5, 8, 24)$

Steiner Tree

The Steiner tree of some subset of the vertices of a GRAPH G is a minimum-weight connected SUBGRAPH of G that includes all the vertices. It is always a tree. Steiner trees have practical applications, for example, in the determination of the shortest total length of wires needed to join some number of points (Hoffman 1998, pp. 164–65).

Steiner Triple System

Let X be a set of $v \geq 3$ elements together with a set B of 3-subset (triples) of X such that every 2-SUBSET of X occurs in exactly one triple of B. Then B is called a Steiner triple system and is a special case of a STEINER SYSTEM with $t = 2$ and $k = 3$. A Steiner triple system $S(v) = S(v,\ k = 3,\ \lambda = 1)$ of order v exists IFF $v \equiv 1,\ 3 \pmod 6$ (Kirkman 1847). In addition, if Steiner triple systems S_1 and S_2 of orders v_1 and v_2 exist, then so does a Steiner triple system S of order $v_1 v_2$ (Ryser 1963, p. 101).

Examples of Steiner triple systems $S(v)$ of small orders v are

$$S_3 = \{\{1,\ 2,\ 3\}\}$$

$$S_7 = \{\{1,\ 2,\ 4\}, \{2,\ 3,\ 5\}, \{3,\ 4,\ 6\}, \{4,\ 5,\ 7\}.$$
$$\{5,\ 6,\ 1\}, \{6,\ 7,\ 2\}, \{7,\ 1,\ 3\}\}$$

$$S_9 = \{\{1,\ 2,\ 3\}, \{4,\ 5,\ 6\}, \{7,\ 8,\ 9\}, \{1,\ 4,\ 7\},$$
$$\{2,\ 5,\ 8\}, \{3,\ 6,\ 9\}, \{1,\ 5,\ 9\}\{2,\ 6,\ 7\},$$
$$\{3,\ 4,\ 8\}, \{1,\ 6,\ 8\}, \{2,\ 4,\ 9\}, \{3,\ 5,\ 7\}\}.$$

The number of nonisomorphic Steiner triple systems $S(v)$ of orders $v = 7, 9, 13, 15, 19, \ldots$ (i.e., $6k + 1.3$) are 1, 1, 2, 80, $> 1.1 \times 10^9$, ... (Colbourn and Dinitz 1996, pp. 14–5; Sloane's A030129). $S(7)$ is the same as the finite PROJECTIVE PLANE of order 2. $S(9)$ is a finite AFFINE PLANE which can be constructed from the array

$$\begin{matrix} a & b & c \\ d & e & f. \\ g & h & i \end{matrix}$$

One of the two $S(13)$s is a finite HYPERBOLIC PLANE. The 80 Steiner triple systems $S(15)$ have been studied by Tonchev and Weishaar (1997). There are more than 1.1×10^9 Steiner triple systems of order 19 (Stinson and Ferch 1985; Colbourn and Dinitz 1996, p. 15).

Steiner's Ellipse

Let $\alpha' : \beta' : \gamma'$ be the ISOTOMIC CONJUGATE POINT of a point with TRILINEAR COORDINATES $\alpha : \beta : \gamma$. The isotomic conjugate of the LINE AT INFINITY having trilinear equation

$$a\alpha + b\beta + c\gamma = 0$$

is

$$\frac{\beta'\gamma'}{a} + \frac{\gamma'\alpha'}{b} + \frac{\alpha'\beta'}{c} = 0.$$

known as Steiner's ellipse (Vandeghen 1965).

Steiner's Problem

For what value of x is $f(x) = x^{1/x}$ a MAXIMUM? The maximum occurs at $x = e$, where

$$f'(x) = x^{-2+1/x}(1 - \ln x) = 0.$$

which is zero at $x = e$ and gives a maximum of

$$e^{1/e} = 1.444667861\ldots.$$

The function has an inflection point at $x = 0.581933\ldots$, where

$$f''(x) = x^{-4+1/x}[1 - 3x + (\ln x)(2x - 2 + \ln x)] = 0.$$

Steiner's Segment Problem

Given n points, find the line segments with the shortest possible total length which connect the points. The segments need not necessarily be straight from one point to another.

For three points, if all ANGLES are less than 120°, then the line segments are those connecting the three points to a central point P which makes the ANGLES $\langle A\rangle PB$, $\langle B\rangle PC$, and $\langle C\rangle PA$ all 120°. If one ANGLE is greater that 120°, then P coincides with the offending ANGLE.

For four points, P is the intersection of the two diagonals, but the required minimum segments are not necessarily these diagonals.

A modified version of the problem is, given two points, to find the segments with the shortest total length connecting the points such that each branch point may be connected to only three segments. There is no general solution to this version of the problem.

Steiner's Theorem

The most common statement known as Steiner's theorem (Casey 1893, p. 329) states that the PASCAL LINES of the HEXAGONS 123456, 143652, and 163254 formed by interchanging the vertices at positions 2, 4, and 6 are concurrent (where the numbers denote the order in which the vertices of the hexagon are taken). The 20 points of concurrence so generated are known as STEINER POINTS.

Another theorem due to Steiner lets LINES x and y join a variable point on a CONIC SECTION to two fixed points on the same CONIC SECTION. Then x and y are PROJECTIVELY related.

A third "Steiner's theorem" states that if two opposite edges of a TETRAHEDRON move on two fixed SKEW LINES in any way whatsoever but remain fixed in length, then the volume of the TETRAHEDRON remains constant (Altshiller-Court 1979, p. 87).

Steinitz's Theorem

A GRAPH G is the edge graph of a POLYHEDRON IFF G is a SIMPLE PLANAR GRAPH which is 3-connected.

See also CONNECTED GRAPH, PLANAR GRAPH, SIMPLE GRAPH

Steinmetz Solid

The solid common to two (or three) right circular CYLINDERS of equal RADII intersecting at RIGHT ANGLES is called the Steinmetz solid. Two CYLINDERS intersecting at RIGHT ANGLES are called a bicylinder, and three intersecting CYLINDERS a TRICYLINDER. Half of a bicylinder is called a VAULT.

For two cylinders of radius r oriented long the z- and x-axes gives the equations

$$x^2 + y^2 = r^2 \quad (1)$$

$$y^2 + z^2 = r^2 \quad (2)$$

which can be solved for x and y gives the PARAMETRIC EQUATIONS of the edges of the solid,

$$x = \pm z \quad (3)$$

$$y = \pm\sqrt{r^2 - z^2}. \quad (4)$$

The SURFACE AREA can be found as $\int x\, ds$, where

$$ds = \sqrt{1 + \left(\frac{dy}{dz}\right)^2}\, dz = \frac{r}{\sqrt{r^2 - z^2}}. \quad (5)$$

Taking the range of integration as a quarter or one face and then multiplying by 16 gives

$$S_2 = 16 \int_0^r \frac{r_2}{\sqrt{r^2 - z^2}}\, dz = 16r^2. \quad (6)$$

The VOLUME common to two cylinders is was known to Archimedes (Heath 1953, Gardner 1962) and the Chinese mathematician Tsu Ch'ung-Chih (Kiang 1972), and does not require CALCULUS to derive. Using calculus provides a simple derivation, however. Noting that the solid has a square CROSS SECTION of side-half-length $\sqrt{a^2 - z^2}$, the volume is given by

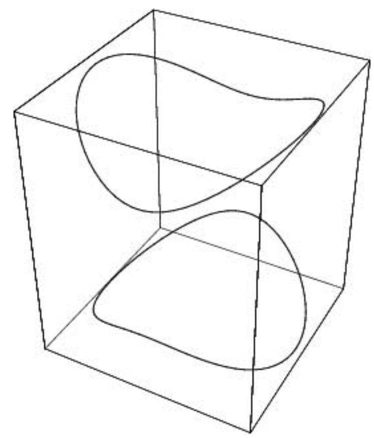
$$V_2(r,\ r) = \int_{-r}^{r} \left(2\sqrt{r^2 - z^2}\right)^2 dz = \tfrac{16}{3} r^3 \quad (7)$$

(Moore 1974). The VOLUME can also be found using CYLINDRICAL ALGEBRAIC DECOMPOSITION, which reduces the inequalities

$$\begin{cases} x^2 + y^2 < 1 \\ -L < z < L \\ y^2 + z^2 < 1 \\ -L < x < L \end{cases} \quad (8)$$

to

$$\begin{cases} -1 < x < 1 \\ -\sqrt{1 - x^2} < y < \sqrt{1 - x^2} \\ -\sqrt{1 - y^2} < z < \sqrt{1 - y^2}, \end{cases} \quad (9)$$



giving the integral

$$V_2(1,\ 1) = \int_{-1}^{1} \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \int_{-\sqrt{1-y^2}}^{\sqrt{1-y^2}} dx\, dy\, dz = \tfrac{16}{3}. \quad (10)$$

If the two right CYLINDERS are of *different* RADII a and b with $a > b$, then the VOLUME common to them is

$$V_2(a,\ b) = \tfrac{8}{3} a \left[(a^2 + b^2) E(k) - (a^2 - b^2) K(k) \right], \quad (11)$$

where $K(k)$ is the complete ELLIPTIC INTEGRAL OF THE FIRST KIND, $E(k)$ is the complete ELLIPTIC INTEGRAL OF THE SECOND KIND, and $k \equiv b/a$ is the MODULUS.

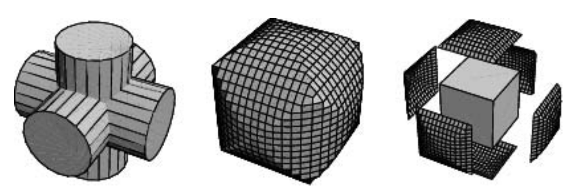
The curves of intersection of two cylinders of RADII a and b, shown above, are given by the parametric equations

$$x(t) = a \cos t \quad (12)$$

$$g(t) = a \sin t \quad (13)$$

$$z(t) = \pm\sqrt{b^2 - a^2 \sin^2 t} \quad (14)$$

(Gray 1997).



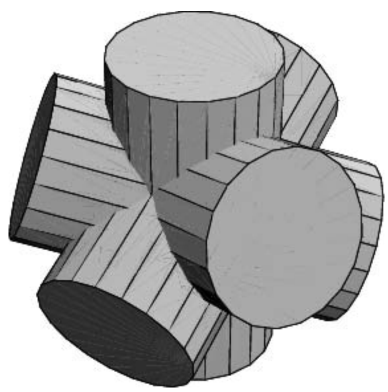
The VOLUME common to two ELLIPTIC CYLINDERS

$$\frac{x^2}{a^2} + \frac{z^2}{c^2} = 1 \quad \frac{y^2}{b^2} + \frac{z^2}{c'^2} = 1 \quad (15)$$

with $c < c'$ is

$$V_2(a,\ c;\ b,\ c') = \frac{8ab}{3c} \left[(c'^2 + c^2) E(k) - (c'^2 - c^2) K(k) \right]. \quad (16)$$

where $k = c/c'$ (Bowman 1961, p. 34).



For three CYLINDERS of RADII r intersecting at RIGHT ANGLES, The resulting solid has 12 curved faces. If tangent planes are drawn where the faces meet, the result is a RHOMBIC DODECAHEDRON (Wells 1991). The VOLUME of intersection can be computed in a number of different ways,

$$V_3(r,\ r,\ r) = \int 16r^3 \int_0^{\pi/4} \int_0^1 s\sqrt{1-s^2\cot^2 t}\, ds\, dt \quad (17)$$

$$= \left(\sqrt{2}r\right)^3 + 6\int_{r/\sqrt{2}}^{r} \left(2\sqrt{r^2-z^2}\right)^2 dz \quad (18)$$

$$= 8\left(2-\sqrt{2}\right)r^3 \quad (19)$$

(Moore 1974).

Four cylinders can also be placed with axes along the lines joining the vertices of a TETRAHEDRON with the centers of the opposite sides. The resulting solid of intersection has VOLUME

$$V_4 = 12\left(2\sqrt{2}-\sqrt{6}\right) \quad (20)$$

and 24 curved faces analogous to a CUBE-OCTAHEDRON COMPOUND (Moore 1974, Wells 1991).

Six cylinders can be place with axes parallel to the face diagonals of a CUBE. The resulting solid of intersection has VOLUME

$$V_4 = 12\left(3+2\sqrt{3}-4\sqrt{2}\right) \quad (21)$$

and 36 curved faces, 24 of which are kite-shaped and 12 of which are rhombic (Moore 1974).

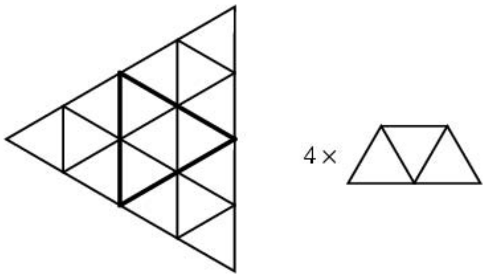
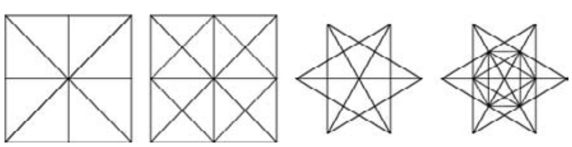
Stella Octangula



A POLYHEDRON COMPOUND composed of a TETRAHEDRON and its DUAL (a second TETRAHEDRON rotated 180° with respect to the first). The stella octangula is also called a STELLATED TETRAHEDRON, and is the only STELLATION of the OCTAHEDRON. The stella octangula can be constructed using the following NET by cutting along the solid lines, folding back along the plain lines, and folding forward along the dotted lines.

Another construction builds a single TETRAHEDRON,

then attaches four tetrahedral caps, one to each face. This CUMULATION of a unit edge-length OCTAHEDRON uses pyramids with height $\frac{1}{3}\sqrt{6}$.



A tetrahedron with edge length 1 produces a stella octangula with edge lengths 1/2. This solid has SURFACE AREA and VOLUME

$$S = \frac{3}{2}\sqrt{3}$$

$$V = \frac{1}{8}\sqrt{2}.$$

The CONVEX HULL of the stella octangula is a CUBE.

The above diagrams show two projections of the stella octangula. The edges lying on tetrahedral faces are represented using dashed lines, while the edges of the two large tetrahedron are showing using solid lines.

The solid common to both tetrahedra is an OCTAHEDRON (left figure; Ball and Coxeter 1987), which is another way of saying that the stella octangula is a STELLATION of the OCTAHEDRON (in fact, the only stellation). The edges of the two tetrahedra in the stella octangula form the 12 DIAGONALS of a CUBE (middle figure). Finally, the stella octangula can be constructed using eight of the 20 vertices of the DODECAHEDRON (right figure).

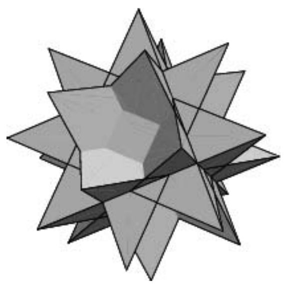
Stellated Octahedron

STELLA OCTANGULA

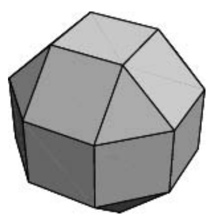


Stellated Polyhedron

STELLATION

Stellated Tetrahedron

STELLA OCTANGULA



Stellated Truncated Hexahedron

The UNIFORM POLYHEDRON U_{19}, also called the QUASITRUNCATED HEXAHEDRON, whose DUAL POLYHEDRON is the GREAT TRIAKIS OCTAHEDRON. It has SCHLÄFLI SYMBOL $t'\{4, 3\}$, WYTHOFF SYMBOL $2 3 | \frac{4}{3}$, and is Wenninger model W_{92}. Its faces are $8\{3\} + 6\{\frac{8}{3}\}$. For $a = 1$, its CIRCUMRADIUS is

$$R = \frac{1}{2}\sqrt{7 - 4\sqrt{2}}.$$

The CONVEX HULL of the stellated truncated hexahedron is the Archimedean SMALL RHOMBICUBOCTAHEDRON A_6, whose dual is the DELTOIDAL ICOSITETRAHEDRON, so the dual of the stellated truncated hexahedron (i.e., the GREAT TRIAKIS OCTAHEDRON) is one of the stellations of the DELTOIDAL ICOSITETRAHEDRON (Wenninger 1983, p. 57).

Stellation

The process of constructing POLYHEDRA by extending the facial PLANES past the EDGES of a given POLYHEDRON until they intersect (Wenninger 1989). The set of all possible EDGES of the stellations can be obtained by finding all intersections on the facial planes. Since the number and variety of intersections can become unmanageable for complicated polyhedra, additional rules are sometimes added to constrain allowable stellations. There exists a *Mathematica* function `Stellate[poly, ratio]` in the *Mathematica* add-on package `Graphics`Polyhedra`` (which can be loaded with the command `<<Graphics``), although it only replaces facial planes with pyramids and does not perform true stellation.

There are no stellations of the CUBE or TETRAHEDRON (Wenninger 1989, p. 35). The only stellated form of the octahedron is the STELLA OCTANGULA, which is a compound of two TETRAHEDRA (Wenninger 1989, pp. 35 and 37). The DODECAHEDRON has three stellations: the SMALL STELLATED DODECAHEDRON, GREAT DODECAHEDRON, and GREAT STELLATED DODECAHEDRON (Wenninger 1989, pp. 35 and 38–0). Coxeter (1982) shows that 59 ICOSAHEDRON STELLATIONS exist, subject to certain restrictions.

The KEPLER-POINSOT SOLIDS, which consist of three DODECAHEDRON STELLATIONS and one of the ICOSAHEDRON STELLATIONS. The only STELLATIONS of PLATONIC SOLIDS which are UNIFORM POLYHEDRA are the three DODECAHEDRON STELLATIONS and one of the ICOSAHEDRON STELLATIONS.

There are three stellations of the RHOMBIC DODECAHEDRON (Wells 1991, pp. 216–17).

Step Function

A function on the REALS $\mathbb{R}$ is a step function if it can be written as a finite linear combination of semi-open intervals $[a, b) \subseteq \mathbb{R}$. Therefore, a step function f can be written as

$$f(x) = \alpha_1 f_1(x) + \cdots + \alpha_n f_n(x).$$

where $\alpha_i \in \mathbb{R}$, $f_i(x) = 1$ if $x \in [a_i, b_i)$ and 0 otherwise, for $i = 1, ..., n$.

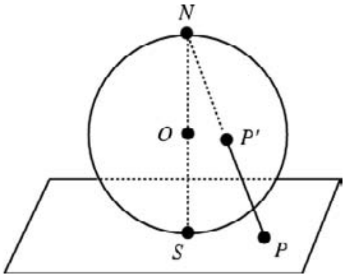
Stereogram



A plane image or pair of 2-D images which, when appropriately viewed using both eyes, produces an image which appears to be three-dimensional. By taking a pair of photographs from slightly different angles and then allowing one eye to view each image, a stereogram is not difficult to produce.
Amazingly, it turns out that the 3-D effect can be produced by both eyes looking at a *single* image by defocusing the eyes at a certain distance. Such stereograms are called "random-dot stereograms."

Stereographic Projection

A MAP PROJECTION obtained by projecting points p' on the surface of sphere from the sphere's north pole N

to point P in a plane tangent to the south pole S (Coxeter 1969, p. 93). In such a projection, GREAT CIRCLES are mapped to CIRCLES, and LOXODROMES become LOGARITHMIC SPIRALS.

The transformation equations for a sphere of radius R are given by

$$x = k \cos\phi \sin(\lambda - \lambda_0) \quad (1)$$

$$y = k[\cos\phi_1 \sin\phi - \sin\phi_1 \cos\phi \cos(\lambda - \lambda_0)]. \quad (2)$$

where λ_0 is the central longitude, ϕ_1 is the central latitude, and

$$k = \frac{2R}{1 + \sin\phi_1 \sin\phi + \cos\phi_1 \cos\phi \cos(\lambda - \lambda_0)}. \quad (3)$$

The inverse FORMULAS for latitude ϕ and longitude λ are then given by

$$\phi = \sin^{-1}\left(\cos c \sin\phi_1 + \frac{y \sin c \cos\phi_1}{\rho}\right) \quad (4)$$

$$\lambda = \lambda_0 + \tan^{-1}\left(\frac{x \sin c}{\rho \cos\phi_1 \cos c - y \sin\phi_1 \sin c}\right), \quad (5)$$

where

$$\rho = \sqrt{x^2 + y^2} \quad (6)$$

$$c = 2 \tan^{-1}\left(\frac{\rho}{2R}\right). \quad (7)$$

For an OBLATE SPHEROID, R can be interpreted as the "local radius," defined by

$$R = \frac{R_e \cos\phi}{(1 - e^2 \sin^2\phi) \cos\chi}, \quad (8)$$

where R_e is the equatorial radius and χ is the CONFORMAL LATITUDE.

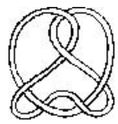
Stern-Brocot Tree



A special type of BINARY TREE obtained by starting with the fractions $\frac{0}{1}$ and $\frac{1}{0}$ and iteratively inserting $(m+m')/(n+n')$ between each two adjacent fractions m/n and m'/n'. The result can be arranged in tree form as illustrated above. The FAREY SEQUENCE F_n defines a subtree of the Stern-Brocot tree obtained by pruning off unwanted branches (Vardi 1991, Graham *et al.* 1994).

Stewart's Theorem

Let a CEVIAN A_1P be drawn on a TRIANGLE $\Delta A_1A_2A_3$, and denote the lengths $m = \overline{A_2P}$ and $n = \overline{PA_3}$, with $a_1 = m + n$. Then

$$ma_2^2 + na_3^2 = (m+n)\overline{A_1P}^2 + m\overline{PA_3}^2 + n\overline{PA_2}^2.$$

This theorem is sometimes also called APOLLONIUS' THEOREM.

Stick Number

Let the stick number $s(K)$ of a KNOT K be the least number of straight sticks needed to make a KNOT K. The smallest stick number of any KNOT is $s(T) = 6$, where T is the TREFOIL KNOT. If J and K are KNOTS, then

$$s(J + K) \leq s(J) + s(K) + 1.$$

For a nontrivial KNOT K, let $c(K)$ be the CROSSING NUMBER (i.e., the least number of crossings in any projection of K). Then

$$\tfrac{1}{2}\left[5 + \sqrt{25 + 8(c(K) - 2)}\right] \leq s(K) \leq 2c(K).$$

The following table gives the stick number for some common knots.

TREFOIL KNOT	6

Stickelberger Relation

Let P be a PRIME IDEAL in D_m not containing m. Then

$$(\Phi(P)) = P^{\sum t\sigma_t^{-1}},$$

where the sum is over all $1 \leq t < m$ which are RELATIVELY PRIME to m. Here D_m is the RING of integers in $\mathbb{Q}(\zeta_m)$, $\Phi(P) = g(P)^m$, and other quantities are defined by Ireland and Rosen (1990).

Stiefel Manifold

The Stiefel manifold of ORTHONORMAL k-frames in $\mathbb{R}^n$ is the collection of vectors $(v_1, ..., v_k)$ where v_i is in $\mathbb{R}^n$ for all i, and the k-tuple $(v_1, ..., v_k)$ is ORTHONORMAL. This is a submanifold of $\mathbb{R}^{nk}$, having DIMENSION $nk - (k+1)k/2$.

Sometimes the "orthonormal" condition is dropped in favor of the mildly weaker condition that the k-tuple ($v_1, ..., v_k$) is linearly independent. Usually, this does not affect the applications since Stiefel manifolds are usually considered only during HOMOTOPY THEORETIC considerations. With respect to HOMOTOPY THEORY, the two definitions are more or less equivalent since GRAM-SCHMIDT ORTHONORMALIZATION gives rise to a smooth deformation retraction of the second type of Stiefel manifold onto the first.

See also GRASSMANN MANIFOLD

Stiefel-Whitney Class

The ith Stiefel-Whitney class of a REAL VECTOR BUNDLE (or TANGENT BUNDLE or a REAL MANIFOLD) is in the ith cohomology group of the base SPACE involved. It is an OBSTRUCTION to the existence of $(n - i + 1)$ REAL linearly independent VECTOR FIELDS on

that VECTOR BUNDLE, where n is the dimension of the FIBER. Here, OBSTRUCTION means that the ith Stiefel-Whitney class being NONZERO implies that there do *not* exist $(n-i+1)$ everywhere linearly dependent VECTOR FIELDS (although the Stiefel-Whitney classes are not always the OBSTRUCTION).

In particular, the nth Stiefel-Whitney class is the obstruction to the existence of an everywhere NONZERO VECTOR FIELD, and the first Stiefel-Whitney class of a MANIFOLD is the obstruction to orientability.

See also CHERN CLASS, OBSTRUCTION, PONTRYAGIN CLASS, STIEFEL-WHITNEY NUMBER

Stiefel-Whitney Number

The Stiefel-Whitney number is defined in terms of the STIEFEL-WHITNEY CLASS of a MANIFOLD as follows. For any collection of STIEFEL-WHITNEY CLASSES such that their cup product has the same DIMENSION as the MANIFOLD, this cup product can be evaluated on the MANIFOLD'S FUNDAMENTAL CLASS. The resulting number is called the PONTRYAGIN NUMBER for that combination of Pontryagin classes.

The most important aspect of Stiefel-Whitney numbers is that they are COBORDISM invariant. Together, PONTRYAGIN and Stiefel-Whitney numbers determine an oriented MANIFOLD'S COBORDISM class.

See also CHERN NUMBER, PONTRYAGIN NUMBER, STIEFEL-WHITNEY CLASS

Stieltjes Constants

N.B. A detailed online essay by S. Finch was the starting point for this entry. Expanding the RIEMANN ZETA FUNCTION about $z=1$ gives

$$\zeta(z)=\frac{1}{z-1}+\sum_{n=0}^{\infty}\frac{(-1)^n}{n!}\gamma_n(z-1)^n, \tag{1}$$

where

$$\gamma_n\equiv\lim_{m\to\infty}\left[\sum_{k=1}^{m}\frac{(\ln k)^n}{k}-\frac{(\ln m)^{n+1}}{n+1}\right]. \tag{2}$$

These constants are returned by the *Mathematica* function StieltjesGamma[n]. An alternative definition is given by absorbing the coefficient of γ_n into the constant,

$$\gamma'_n\equiv\frac{(-1)^n}{n!}\gamma_n \tag{3}$$

(e.g., Hardy 1912, Kluyver 1927).

The case $n=0$ gives the usual EULER-MASCHERONI CONSTANT $\gamma_0\equiv\gamma$. The first few numerical values are given in the following table.

n	γ_n
0	0.5772156649
1	−0.07281584548
2	−0.009690363192
3	0.002053834420
4	0.002325370065
5	0.0007933238173

Briggs (1955–956) proved that there infinitely many γ_n of each SIGN. Berndt (1972) gave upper bounds of

$$|\gamma_n|<\begin{cases}\dfrac{4(n-1)!}{\pi^n} & \text{for } n \text{ even}\\[2ex] \dfrac{2(n-1)!}{\pi^n} & \text{for } n \text{ odd.}\end{cases} \tag{4}$$

However, these bounds are extremely weak, so it is likely that better ones can be derived.

Vacca (1910) proved that the EULER-MASCHERONI CONSTANT may be expressed as

$$\gamma=\sum_{k=1}^{\infty}\frac{(-1)^k}{k}\lfloor\lg k\rfloor, \tag{5}$$

where $\lfloor x\rfloor$ is the FLOOR FUNCTION and the LG function $\lg x\equiv\log_2 x$ is the LOGARITHM to base 2.

Hardy (1912) gave the FORMULA

$$\frac{2\gamma_1}{\ln 2}=\sum_{k=1}^{\infty}\frac{(-1)^k}{k}[2\lg k-\lfloor\lg(2k)\rfloor]\lfloor\lg k\rfloor. \tag{6}$$

γ_1 is also given by the sum

$$\sum_{n=1}^{x}\frac{1}{n}\ln\left(\frac{x}{n}\right)=\tfrac{1}{2}(\ln x)^2+\gamma\ln x-\gamma_1+\mathcal{O}(x^{-1}), \tag{7}$$

where γ_1 was called $-D$ and given incorrectly by Ellision and Mendès-France (1975) and the error was reproduced by Le Lionnais (1983, p. 47). The exact form of (7) is given by

$$\sum_{n=1}^{x}\frac{1}{n}\ln\left(\frac{x}{n}\right)=H_x\ln x-\zeta'(1,x+1)+\gamma_1, \tag{8}$$

where H_x is a HARMONIC NUMBER, $\mathbb{Q}(\zeta_m)$ is the HURWITZ ZETA FUNCTION, and $\zeta'(1,a)$ denotes $\lim_{s\to 1} d\zeta(s,a)/dz|_{z=s}$.

Kluyver (1927) gave similar series for γ_n valid for all $n>1$,

$$\gamma_n = n!(\ln 2)^n \sum_{m=1}^{n+1} \frac{(-1)^{m-1}}{m!} \sum_{k=1}^{\infty} \frac{(-1)^k}{k\lfloor \lg k \rfloor^m} B_{1+n-m}\left(\frac{\ln k}{\ln 2}\right), \quad (9)$$

where $B_n(x)$ is a BERNOULLI POLYNOMIAL. However, this series converges extremely slowly, requiring more than 10^4 terms to get two digits of γ_1 and many more for higher order γ_n. γ_n can also be expressed as a single sum using

$$\gamma_n = \frac{(\ln 2)^n}{n+1} \sum_{k=1}^{\infty} \frac{(-1)^k}{k} B_{n+1}\left(\frac{\ln k}{\ln 2}\right). \quad (10)$$

A set of constants related to γ_n is

$$\delta_n \equiv \lim_{m\to\infty} \left[\sum_{k=1}^{m} (\ln k)^n - \int_1^m (\ln x)^n \, dx - \tfrac{1}{2}(\ln m)^n\right] \quad (11)$$

(Sitaramachandrarao 1986, Lehmer 1988).

Stieltjes Integral

The Stieltjes integral is a generalization of the RIEMANN INTEGRAL. Let $f(x)$ and $\alpha(x)$ be real-valued bounded functions defined on a CLOSED INTERVAL $[a, b]$. Take a partition of the INTERVAL

$$a = x_0 < x_1 < x_2, \ldots < x_{n-1} < x_n = b, \quad (1)$$

and consider the Riemann sum

$$\sum_{i=0}^{n-1} f(\xi_i)\left[\alpha(x_{i+1}) - \alpha(x_i)\right] \quad (2)$$

with $\xi_i \in [x_i, x_{i+1}]$. If the sum tends to a fixed number I as $\max(x_{i+1} - x_i) \to 0$, then I is called the Stieltjes integral, or sometimes the RIEMANN-STIELTJES INTEGRAL. The Stieltjes integral of f with respect to α is denoted

$$\int f(x)\, d\alpha(x) \quad (3)$$

or sometimes simply

$$\int f\, d\alpha. \quad (4)$$

If f and α have a common point of discontinuity, then the integral does not exist. However, if f is continuous and α' is Riemann integrable over the specified interval, then

$$\int f(x)\, d\alpha(x) = \int f(x)\alpha'(x)\, dx \quad (5)$$

(Kestelman 1960).

For enumeration of many properties of the Stieltjes integral, see Dresher (1981, p. 105).

Stirling Cycle Number

STIRLING NUMBER OF THE FIRST KIND

Stirling Number of the First Kind

The *signed* Stirling numbers of the first kind are variously denoted $s(n, m)$ (Riordan 1980, Roman 1984), $S_n^{(m)}$ (Fort 1958, Abramowitz and Stegun 1971), S_n^m (Jordan 1950). Abramowitz and Stegun (1971, p. 822) summarize the various notational conventions, which can be a bit confusing (especially since an *unsigned* version $S_1(n, m) = |s(n, m)|$ is also in common use). The signed Stirling number of the first kind $s(n, m)$ is are returned by `StirlingS1[n, m]` in *Mathematica*.

The signed Stirling numbers of the first kind $s(n, m)$ are defined such that the number of PERMUTATIONS of n elements which contain exactly m CYCLES is the *nonnegative* number

$$|s(n, m)| = (-1)^{n-m} s(n, m). \quad (1)$$

This means that $s(n, m) = 0$ for $m > n$ and $s(n, n) = 1$. A related set of numbers is known as the associated Stirling numbers of the first kind. Both these are the usual Stirling numbers of the first kind are special cases of a general function $d_r(n, k)$ which is related to the number of cycles in a permutation.

The triangle of signed Stirling numbers of the first kind is

$$\begin{array}{c} 1 \\ -1 \quad 1 \\ 2 \quad -3 \quad 1 \\ -6 \quad 11 \quad -6 \quad 1 \\ 24 \quad -50 \quad 35 \quad -10 \quad 1 \end{array}$$

(Sloane's A008275). Special values include

$$s(n,\ 0) = \delta_{n0} \tag{2}$$

$$s(n,\ 1) = (-1)^{n-1}(n-1)! \tag{3}$$

$$s(n,\ 2) = (-1)^{n}(n-1)!H_{n-1} \tag{4}$$

$$s(n,\ 3) = \tfrac{1}{2}(-1)^{n-1}(n-1)!\left[H_{n-1}^{2} - H_{n-1}^{(2)}\right] \tag{5}$$

$$s(n,\ n-1) = -\binom{n}{2}, \tag{6}$$

where δ_{mn} is the KRONECKER DELTA, H_n is a HARMONIC NUMBER, $H_n^{(r)}$ is a HARMONIC NUMBER of order r, and $\binom{n}{k}$ is a BINOMIAL COEFFICIENT.

The GENERATING FUNCTION for the Stirling numbers of the first kind is

$$(x)_n = x(x-1)\cdots(x-n+1) = \sum_{m=0}^{n} s(n,\ m)x^m, \tag{7}$$

where $(x)_n$ is a FALLING FACTORIAL. Other generating functions are

$$\sum_{k=0}^{n} s(n,\ k)x^k = (1+x-n)_n \tag{8}$$

$$\sum_{k=0}^{n} s(n,\ k)x^k = (-1)^n n!\binom{n-x-1}{n} \tag{9}$$

$$\sum_{k=m}^{\infty} s(k,\ m)x^k = \frac{[\ln(x+1)]^m}{m!} \tag{10}$$

$$\prod_{k=1}^{n}(1+kx) = \sum_{k=1}^{n+1}(-1)^{n+1-k}s(n+1,\ k)x^{n+1-k}. \tag{11}$$

The Stirling numbers of the first kind satisfies the RECURRENCE RELATION

$$s(n+1,\ m) = s(n,\ m-1) - ns(n,\ m) \tag{12}$$

for $1 \leq m \leq n$ and the sum identities

$$s(n,\ m) = \sum_{k=m}^{n} n^{k-m}s(n+1,\ k+1) \tag{13}$$

for $m \geq 1$ and

$$\binom{m}{r}s(n,\ m) = \sum_{k=m-r}^{n-r}\binom{n}{k}s(n-k,\ r)(k,\ m-r) \tag{14}$$

for $0 \leq r \leq m$, where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT.

The Stirling numbers of the first kind $s(n,\ m)$ are connected with the STIRLING NUMBERS OF THE SECOND KIND $S(n,\ m)$ through the formulas

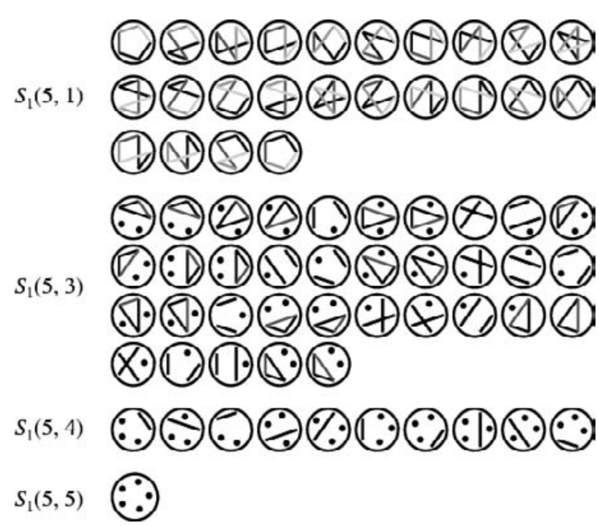
$$s(n,\ i) = \sum_{k=i}^{n}\sum_{j=0}^{k} s(n,\ k)s(k,\ j)S(j,\ i) \tag{15}$$

$$S(n,\ i) = \sum_{k=i}^{n}\sum_{j=0}^{k} S(n,\ k)S(k,\ j)s(j,\ i) \tag{16}$$

(Roman 1984, p. 67), as well as

$$S(n,\ m) = \sum_{k=0}^{n-m}(-1)^k\binom{k+n-1}{k+n-m} \times \binom{2n-m}{n-k-m}s(k-m+n,\ k) \tag{17}$$

$$s(n,\ m) = \sum_{k=0}^{n-m}(-1)^k\binom{k+n-1}{k+n-m} \times \binom{2n-m}{n-k-m}s(k-m+n,\ k) \tag{18}$$



$$\sum_{l=0}^{\max(k,\ j)+1} s(l,\ j)S(k,\ 1) = \delta_{jk} \tag{19}$$

$$\sum_{l=0}^{\max(k,\ j)+1} s(k,\ l)S(l,\ j) = \delta_{jm}. \tag{20}$$

The NONNEGATIVE version simply gives the number of PERMUTATIONS of n objects having m CYCLES (with cycles in opposite directions counted as distinct) and is obtained by taking the ABSOLUTE VALUE of the signed version. The nonnegative Stirling numbers of the first kind are variously denoted

$$S_1(n,\ m) \equiv \begin{bmatrix} n \\ m \end{bmatrix} \equiv |s(n,\ m)| \tag{21}$$

(Graham *et al.* 1994). Diagrams illustrating $S_1(5,\ 1) = 24$, $S_1(5,\ 3) = 35$, $S_1(5, 4) = 10$, and $S_1(5,\ 5) = 1$ (Dickau) are shown below.

The nonnegative Stirling numbers of the first kind satisfy the curious identity

$$\sum_{n=1}^{\infty}\left[\sum_{k=0}^{n-2}\frac{(e^x-x-1)^{k+1}S_1(n,\ n-k)}{(k+1)!}\right]e^{-xn}$$
$$=\ln(x+1) \tag{22}$$

(Gosper) and satisfy

$$S_1(n+1,\ k)=nS_1(n,\ k)+S_1(n,\ k-1). \tag{23}$$

The Stirling numbers can be generalized to nonintegral arguments (a sort of "Stirling polynomial") using the identity

$$\frac{\Gamma(j+h)}{j^h\Gamma(j)}=\sum_{k=0}^{\infty}\frac{S_1(h,\ h-k)}{j^k}$$

$$=1+\frac{(h-1)h}{2j}+\frac{(h-2)(3h-1)(h-1)h}{24j^2}$$
$$+\frac{(h-3)(h-2)(h-1)^2h^2}{48j^3}+\cdots \tag{24}$$

which is a generalization of an ASYMPTOTIC SERIES for a ratio of GAMMA FUNCTIONS $\Gamma(j+1/2)/\Gamma(j)$ (Gosper).

The associated Stirling numbers of the first kind $d_2(n,\ k)=d(n,\ k)$ are defined as the number of permutations of a given number n having exactly k CYCLES, all of which are of length $r=2$ or greater (Comtet 1974, p. 256; Riordan 1980, p. 75). They are a special case of the more general numbers $d_r(n,\ k)$, and have the RECURRENCE RELATION

$$d_2(n+1,\ k)=n[d_2(n,\ k)+d_2(n-1,\ k-1)] \tag{25}$$

with initial conditions $d_2(n,\ k)=0$ for $n\le 2k-1$, and $d_2(n,\ 1)=(n-1)!$ (Appell 1880; Tricomi 1951; Carlitz 1958; Comtet 1974, pp. 256, 293, and 295) with . The GENERATING FUNCTION for $d_2(n,\ k)$ is given by

$$e^{-tu}(1-t)^{-u}=1+\sum_{k=1}^{n/2}\frac{d_2(n,\ k)}{n!}\,t^nu^k$$

$$=1+\left(\frac{t^2}{2}+\frac{t^3}{3}+\frac{t^4}{4}+\frac{t^5}{5}+\frac{t^6}{6}+\ldots\right)u$$

$$+\left(\frac{t^4}{8}+\frac{t^5}{6}+\frac{13t^6}{72}+\ldots\right)u^2+\left(\frac{t^6}{48}+\ldots\right)u^3+\ldots \tag{26}$$

(Comtet 1974, p. 256). The associated Stirling numbers of the first kind satisfy the sum identity

$$\sum_{k=1}^{n}(-1)^{k-1}d_2(n,\ k)=n-1. \tag{27}$$

For $k\ge 2$ and p a PRIME,

$$d(p,\ k)\equiv 0\pmod{p(p-1)}. \tag{28}$$

For all integers l,

$$\sum_m(-1)^m d_2(l+m,\ m)=(-1)^l, \tag{29}$$

and similarly,

$$\sum_m\frac{(-1)^m d_2(l+m,\ m)}{l+m-1}=0 \tag{30}$$

(Comtet 1974, p. 256).

Special cases of the associated Stirling numbers of the first kind are given by

$$d_2(n,\ 1)=(n-1)! \tag{31}$$

$$d_2(2k,\ k)=(2k-1)!! \tag{32}$$

$$d_2(2k+1,\ k)=\frac{(2k+1)a_k!}{3(k-1)!2^k} \tag{33}$$

$$d_2(2k+2,\ k)=\frac{(4k+5)(2k+2)!}{18(k-1)!2^k} \tag{34}$$

(Comtet 1974, p. 256), where a_k is a coefficient in the expansion of $(1+3x)/(1-2x)^{7/2}$: 1, 10, 105, 1260, 17325, ... (Sloane's A000457), omitted in Comtet (1974). The triangle of these numbers is given by

1

2

6, 3

24, 20

120, 130, 15

720, 924, 210

5040, 7308, 2380, 105

(Sloane's A008306).

Stirling Number of the Second Kind

The number of ways of partitioning a set of n elements into m nonempty SETS (i.e., m BLOCKS), also called a STIRLING SET NUMBER. for example, the SET $\{1, 2, 3\}$ can be partitioned into three SUBSETS in one way: $\{\{1\}, \{2\}, \{3\}\}$; into two SUBSETS in three ways: $\{\{1, 2\}, \{3\}\}$, $\{\{1, 3\}, \{2\}\}$, and $\{\{1\}, \{2, 3\}\}$; and into one SUBSET in one way: $\{\{1, 2, 3\}\}$.

The Stirling numbers of the second kind are variously denoted $S(n, m)$ (Riordan 1980, Roman 1984), $S_n^{(m)}$ (Fort 1958, Abramowitz and Stegun 1971), $\mathfrak{S}_n^m$ (Jordan 1950), $s_n^{(m)}$, $S_2(n, m)$, or $\left\{ n \atop m \right\}$ (Graham *et al.* 1994). Abramowitz and Stegun (1971, p. 822) summarize the various notational conventions, which can be a bit confusing. The *Mathematica* command for a Stirling number of the second kind is `StirlingS2[n, m]`. The Stirling numbers of the second kind for three elements are

$$S(3, 1) = 1 \tag{1}$$

$$S(3, 2) = 3 \tag{2}$$

$$S(3, 3) = 1. \tag{3}$$

Since a set of n elements can only be partitioned in a single way into 1 or n SUBSETS,

$$S(n, 1) = S(n, n) = 1. \tag{4}$$

Other special cases include

$$S(n, 0) = \delta_{n0} \tag{5}$$

$$S(n, 2) = 2^{n-1} - 1 \tag{6}$$

$$S(n, n-1) = \binom{n}{2}. \tag{7}$$

The triangle of Stirling numbers of the second kind is

$$\begin{array}{c} 1 \\ 1 \quad 1 \\ 1 \quad 3 \quad 1 \\ 1 \quad 7 \quad 6 \quad 1 \\ 1 \quad 15 \quad 25 \quad 10 \quad 1 \\ 1 \quad 31 \quad 90 \quad 65 \quad 15 \quad 1 \end{array}$$

(Sloane's A008277), the nth row of which corresponds to the coefficients of the EXPONENTIAL POLYNOMIAL $\phi_n(x)$.

The Stirling numbers of the second kind can be computed from the sum

$$S(n, k) = \frac{1}{k!} \sum_{i=0}^{k-1} (-1)^i \binom{k}{i} (k-i)^n, \tag{8}$$

with $\binom{n}{k}$ a BINOMIAL COEFFICIENT, or the GENERATING FUNCTIONS

$$x^n = \sum_{m=0}^{n} S(n, m)(x)_m$$

$$= \sum_{m=0}^{n} S(n, m) x(x-1)\cdots(x-m+1), \tag{9}$$

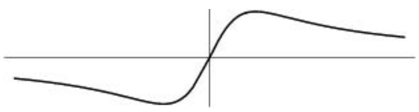
where $(x)_m$ is the FALLING FACTORIAL (Roman 1984, pp. 60 and 101),

$$\sum_{n \geq k} S(n, k) \frac{x^n}{n!} = \frac{1}{k!} (e^x - 1)^k, \tag{10}$$

and

$$\frac{1}{(1-x)(1-2x)\cdots(1-kx)} = \sum_{n=1}^{k} S(n, k) x^n. \tag{11}$$

Other generating functions are



$$\sum_{k-1}^{n} S(n, k)(k-1)! z^k = (-1)^n \operatorname{Li}_{1-n}(1 + 1/z) \tag{12}$$

for $n \geq 2$, where $\operatorname{Li}_n(z)$ is the POLYLOGARITHM, and

$$\sum_{k=m}^{\infty} S(k, m)z^k = \frac{z^m}{\prod_{k=1}^{\infty}(1-kz)}. \qquad (13)$$

Stirling numbers of the second kind are intimately connected with the POISSON DISTRIBUTION through the identity

$$\sum_{k=0}^{\infty} \frac{e^{-x}x^k}{k!} k^n = \sum_{k=1}^{n} x^k S(n, k). \qquad (14)$$

The above diagrams (Dickau) illustrate the definition of the Stirling numbers of the second kind $S(n, m)$ for $n = 3$ and 4. Stirling numbers of the second kind obey the RECURRENCE RELATIONS

$$S(n, k) = S(n-1, k-1) + kS(n-1, k) \qquad (15)$$

$$S(n, k) = \sum_{m=k}^{n} k^{n-m} S(m-1, k-1). \qquad (16)$$

The STIRLING NUMBERS OF THE FIRST KIND $s(n, m)$ are connected with the Stirling numbers of the second kind $S(n, m)$ through the formulas

$$s(n, i) = \sum_{k=i}^{n} \sum_{j=0}^{k} s(n, k)s(k, j)S(j, i) \qquad (17)$$

$$S(n, i) = \sum_{k=i}^{n} \sum_{j=0}^{k} S(n, k)S(k, j)s(j, i) \qquad (18)$$

(Roman 1984, p. 67), as well as

$$S(n, m) = \sum_{k=0}^{n-m} (-1)^k \binom{k+n-1}{k+n-m} \times \binom{2n-m}{n-k-m} s(k-m+n, k) \qquad (19)$$

$$s(n, m) = \sum_{k=0}^{n-m} (-1)^k \binom{k+n-1}{k+n-m} \times \binom{2n-m}{n-k-m} s(k-m+n, k) \qquad (20)$$

$$\sum_{l=0}^{\max(k, j)+1} s(l, j)S(k, 1) = \delta_{jk} \qquad (21)$$

$$\sum_{l=0}^{\max(k, j)+1} s(k, l)S(l, j) = \delta_{jm}. \qquad (22)$$

Identities involving Stirling numbers of the second kind are given by

$$\sum_{m=1}^{n} (-1)^m (m-1)! S(n, m) = 0 \qquad (23)$$

$$\sum_{k=0}^{m} k^n = \sum_{k=0}^{n} k! \binom{m+1}{k+1} S(n, k) \qquad (24)$$

$$f(m, n) \equiv \sum_{k=1}^{\infty} k^n \left(\frac{m}{m+1}\right)^l = (m+1)\sum_{k=1}^{m} k! S(n, k) m^k. \qquad (25)$$

It turns out that $f(1, n)$ can have only 0, 2, or 6 as a last DIGIT (Riskin 1995).

The Stirling numbers of the second appear in the operator identity

$$(x\tilde{D})^n = \sum_{k=0}^{n} S(n, k) x^k f^{(k)}, \qquad (26)$$

where $\tilde{D}$ is the differential operator d/dx (Roman 1984, p. 144), giving

$$(x\tilde{D})^1 = x\tilde{D} \qquad (27)$$

$$(x\tilde{D})^2 = x\tilde{D} + x^2\tilde{D}^2 \qquad (28)$$

$$(x\tilde{D})^3 = x\tilde{D} + 3x^2\tilde{D}^2 + x^3\tilde{D}^3 \qquad (29)$$

$$(x\tilde{D})^4 = x\tilde{D} + 7x^2\tilde{D}^2 + 6x^3\tilde{D}^3 + x^4\tilde{D}^4 \qquad (30)$$

and so on. Similarly,

$$[(x-a)\tilde{D}]^n = \sum_{k=0}^{n} S(n, k)(x-a)^k \tilde{D}^k \qquad (31)$$

(Roman 1984, p. 146).

Stirling Polynomial

Polynomials $S_k(x)$ which form the SHEFFER SEQUENCE for

$$g(t) = e^{-t} \tag{1}$$

$$f^{-1}(t) = \ln\left(\frac{1}{1-e^{-t}}\right), \tag{2}$$

where $f^{-1}(t)$ is the INVERSE FUNCTION of $f(t)$, and have GENERATING FUNCTION

$$\sum_{k=0}^{\infty} \frac{S_k(x)}{k!} t^k = \left(\frac{t}{1-e^{-t}}\right)^{x+1}. \tag{3}$$

The first few polynomials are

$$S_0(x) = 1$$
$$S_1(x) = \tfrac{1}{2}(x+1)$$
$$S_2(x) = \tfrac{1}{12}(3x+2)(x+1)$$
$$S_3(x) = \tfrac{1}{8}x(x+1)^2.$$

The Stirling polynomials are related to the STIRLING NUMBERS OF THE FIRST KIND $s(n, m)$ by

$$S_n(m) = \frac{(-1)^n}{\binom{m}{n}} s(m+1, m-n+1), \tag{4}$$

where $\binom{m}{n}$ is a BINOMIAL COEFFICIENT and m is an integer with $m \geq n$, and to STIRLING NUMBERS OF THE SECOND KIND $S(n, m)$ by

$$S_n(m) = \frac{(-1)^n n!}{(n-m-1)!} S(n-m-1, -m-1) \tag{5}$$

for m a NEGATIVE INTEGER.

Stirling Set Number

STIRLING NUMBER OF THE SECOND KIND

Stirling Transform

The transformation of a sequence a_1, a_2, ... into a sequence b_1, b_2, ..., by the formula

$$b_n = \sum_{k=0}^{n} S(n, k) a_k,$$

where $S(n, k)$ is a STIRLING NUMBER OF THE SECOND KIND. The inverse transform is given by

$$a_n = \sum_{k=0}^{n} s(n, k) b_k,$$

where $s(n, k)$ is a STIRLING NUMBER OF THE FIRST KIND (Sloane and Plouffe 1995, p. 23).

The Stirling transform of $a_n = 1$ for all n gives the BELL NUMBERS 1, 2, 5, 15, 52, ... (Sloane's A000110). The Stirling transform of $a_n = n$ gives 1, 3, 10, 37, 151, 674, ... (Sloane's A005493), which has EXPONENTIAL GENERATING FUNCTION

$$g(x) = \exp(e^x + 2x - 1).$$

The Stirling transform of the sequence $a_n = 1$ for n prime and $a_n = 0$ for n composite is 0, 1, 4, 13, 41, 136, 505, ... The Stirling transform of the sequence $a_n = 1$ for n even and $a_n = 0$ for n odd is 0, 1, 3, 8, 25, 97, 434, 2095, ... (Sloane's A024430). The Stirling transform of the sequence $a_n = 0$ for n even and $a_n = 1$ for n odd is 1, 1, 2, 7, 27, 106, 443, ... (Sloane's A024429). The inverse Stirling transform of $b_n = n$ is given by the sequence of signed factorials 1, 1, -1, 2, -6, 24, -120, ...

Stirling's Approximation

Stirling's approximation gives an approximate value for the FACTORIAL function $n!$ or the GAMMA FUNCTION $\Gamma(n)$ for $n \gg 1$. The approximation can most simply be derived for n an INTEGER by approximating the sum over the terms of the FACTORIAL with an INTEGRAL, so that

$$\ln n! = \ln 1 + \ln 2 + \ldots + \ln n = \sum_{k=1}^{n} \ln k \approx \int_1^n \ln x\,dx$$

$$= [x \ln x - x]_1^n = n \ln n - n + 1 \approx n \ln n - n. \quad (1)$$

The equation can also be derived using the integral definition of the FACTORIAL,

$$n! = \int_0^\infty e^{-x} x^n\,dx. \quad (2)$$

Note that the derivative of the LOGARITHM of the integrand can be written

$$\frac{d}{dx}\ln(e^{-x}x^n) = \frac{d}{dx}(n \ln x - x) = \frac{n}{x} - 1. \quad (3)$$

The integrand is sharply peaked with the contribution important only near $x = n$. Therefore, let $x \equiv n + \xi$ where $\xi \ll n$, and write

$$\ln(x^n e^{-x}) = n \ln x - x = n \ln(n+\xi) - (n+\xi). \quad (4)$$

Now,

$$\ln(n+\xi) = \ln\left[n\left(1+\frac{\xi}{n}\right)\right] = \ln n + \ln\left(1+\frac{\xi}{n}\right)$$

$$= \ln n + \frac{\xi}{n} - \frac{1}{2}\frac{\xi}{n^2} + \cdots, \quad (5)$$

so

$$\ln(x^n e^{-n}) = n \ln(n+\xi) - (n+\xi)$$

$$= n \ln n + \xi - \frac{1}{2}\frac{\xi^2}{n} - n - \xi + \ldots$$

$$= n \ln n - n - \frac{\xi^2}{2n} + \ldots \quad (6)$$

Taking the EXPONENTIAL of each side then gives

$$x^n e^{-x} \approx e^{n \ln n} e^{-n} e^{-\xi^2/2n} = n^n e^{-n} e^{-\xi^2/2n}. \quad (7)$$

Plugging into the integral expression for $n!$ then gives

$$n! \approx \int_{-n}^\infty n^n e^{-n} e^{-\xi^2/2n}\,d\xi \approx n^n e^{-n} \int_{-\infty}^\infty e^{-\xi^2/2n}\,d\xi. \quad (8)$$

Evaluating the integral gives

$$n! \approx n^n e^{-n}\sqrt{2\pi n}. \quad (9)$$

$$= \sqrt{2\pi}\, n^{n+1/2} e^{-n} \quad (10)$$

(Wells 1986, p. 45). Taking the LOGARITHM of both sides then gives

$$\ln n! \approx n \ln n - n + \tfrac{1}{2}\ln(2\pi n)$$

$$= \left(n+\tfrac{1}{2}\right)\ln n - n + \tfrac{1}{2}\ln(2\pi). \quad (11)$$

This is STIRLING'S SERIES with only the first term retained and, for large n, it reduces to Stirling's approximation

$$\ln n! \approx n \ln n - n. \quad (12)$$

Taking successive terms of $\lfloor n^n/n! \rfloor$ where $\lfloor x \rfloor$ is the FLOOR FUNCTION, gives the sequence 1, 2, 4, 10, 26, 64, 163, 416, 1067, 2755, ... (Sloane's A055775).

Stirling's approximation can be extended to the double inequality

$$\sqrt{2\pi} n^{n+1/2} e^{-n+1/(12n+1)} < n!$$
$$< \sqrt{2\pi} n^{n+1/2} e^{-n+1/(12n)} \quad (13)$$

(Robbins 1955, Feller 1968).

Gosper has noted that a better approximation to $n!$ (i.e., one which approximates the terms in STIRLING'S SERIES instead of truncating them) is given by

$$n! \approx \sqrt{\left(2n+\tfrac{1}{3}\right)\pi}\, n^n e^{-n}. \quad (14)$$

This also gives a much closer approximation to the FACTORIAL of 0, $0! = 1$, yielding $\sqrt{\pi/3} \approx 1.02333$ instead of 0 obtained with the conventional Stirling approximation.

Stirling's Formula

STIRLING'S APPROXIMATION, STIRLING'S SERIES

Stirling's Series

The ASYMPTOTIC SERIES for the GAMMA FUNCTION is given by

$$\Gamma(z) \sim e^{-z} z^{z-1/2} \sqrt{2\pi} \times \left(1 + \frac{1}{12z} + \frac{1}{288z^2} - \frac{139}{51840z^3} - \frac{571}{2488320z^4} + \ldots\right) \quad (1)$$

(Sloane's A001163 and A001164).

The coefficient a_n of z^{-n} can given explicitly by

$$a_n = \sum_{k=1}^{2n} (-1)^k \frac{d_3(2n+2k, k)}{2^{n+k}(n+k)!}, \quad (2)$$

where $d_3(n, k)$ is the number of permutations of n with k CYCLES all of which are ≥ 3 (Comtet 1974, p. 267). Another formula for the a_ns is given by the recurrence relation

$$b_n = \frac{1}{n+1} \left(b_{n-1} - \sum_{k=2}^{n-1} k a_k a_{n+1-k}\right), \quad (3)$$

with $b_0 = b_1 = 1$, then

$$a_n = (2n+1)!! b_{2n+1}. \quad (4)$$

where $x!!$ is the DOUBLE FACTORIAL (Borwein and Corless 1999).

The series for $z!$ is obtained by adding an additional factor of z,

$$z! = \Gamma(z+1) = e^{-z} z^{z+1/2} \sqrt{2\pi} \times \left(1 + \frac{1}{12z} + \frac{1}{288z^2} - \frac{139}{51840z^3} - \frac{571}{2488320z^4} + \ldots\right). \quad (5)$$

The expansion of $\ln \Gamma(z)$ is what is usually called Stirling's series. It is given by the simple analytic expression

$$\ln \Gamma(z) = \sum_{n=1}^{\infty} \frac{B_{2n}}{2n(2n-1) z^{2n-1}} \quad (6)$$

$$= \tfrac{1}{2} \ln(2\pi) + \left(z - \tfrac{1}{2}\right) \ln z - z + \frac{1}{12z} - \frac{1}{360z^3} + \frac{1}{1260z^5} - \ldots \quad (7)$$

where B_n is a BERNOULLI NUMBER.

See also BERNOULLI NUMBER, CYCLE (PERMUTATION), *K*-FUNCTION, STIRLING'S APPROXIMATION

Stochastic Group

The group of all nonsingular $n \times n$ stochastic matrices over a field F. It is denoted $S(n, F)$. If p is prime and F is the finite field of order $q = p^m$, $S(n, q)$ is written instead of $S(n, F)$. Particular examples include

$$S(2,\ 2) = \mathbb{Z}_2$$

$$S(2,\ 3) = S_3$$

$$S(2,\ A) = A_4$$

$$S(3,\ 2) = S_4$$

$$S(2,\ 5) = \mathbb{Z}_4 \times_\theta \mathbb{Z}_5$$

where $\mathbb{Z}_2$ is an Abelian group, S_n are symmetric groups on n elements, and $\times_\theta$ denotes the semidirect product with $\theta : \mathbb{Z}_4 \to \mathrm{Aut}(\mathbb{Z}_5)$ (Poole 1995).

References

Poole, D. G. "The Stochastic Group." *Amer. Math. Monthly* **102**, 798–01, 1995.

Stochastic Matrix

A stochastic matrix is the transition matrix for a finite Markov chain, also called a Markov matrix. Elements of the matrix must be real numbers in the closed interval [0, 1].

A completely independent type of stochastic matrix is defined as a square matrix with entries in a field F such that the sum of elements in each column equals 1. There are two nonsingular 2×2 stochastic matrices over $\mathbb{Z}_2$ (i.e., the integers mod 2),

$$\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}.$$

There are six nonsingular stochastic 2×2 matrices over $\mathbb{Z}_3$,

$$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 2 \\ 1 & 2 \end{bmatrix}, \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} 1 & 2 \\ 0 & 2 \end{bmatrix}, \begin{bmatrix} 2 & 0 \\ 2 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 1 \\ 2 & 0 \end{bmatrix},$$

In fact, the set S of all nonsingular stochastic $n \times n$ matrices over a FIELD F forms a GROUP under MATRIX MULTIPLICATION. This GROUP is called the STOCHASTIC GROUP.

The following tables give the number of distinct stochastic matrices (and distinct nonsingular stochastic matrices) over $\mathbb{Z}_m$ for small m.

m	stochastic $n \times n$ matrices over Z^m
2	1, 4, 64, 4096, ...
3	1, 9, 729, ...
4	1, 16, 4096, ...

m	stochastic nonsingular $n \times n$ matrices over Z^m
2	1, 2, 24, 1440, ...
3	1, 6, 450, ...
4	1, 12, 3108, ...

References

Poole, D. G. "The Stochastic Group." *Amer. Math. Monthly* **102**, 798–01, 1995.

Stochastic Optimization

Stochastic optimization refers to the minimization (or maximization) of a function in the presence of randomness in the optimization process. The randomness may be present as either noise in measurements or Monte Carlo randomness in the search procedure, or both.

Common methods of stochastic optimization include direct search methods (such as the NELDER-MEAD METHOD), STOCHASTIC APPROXIMATION, stochastic programming, and miscellaneous methods such as SIMULATED ANNEALING and GENETIC ALGORITHMS.

See also GENETIC ALGORITHM, NELDER-MEAD METHOD, OPTIMIZATION, OPTIMIZATION THEORY, ROBBINS-MONRO STOCHASTIC APPROXIMATION, SIMULATED ANNEALING, STOCHASTIC APPROXIMATION

Stochastic Process

Doob (1996) defines a stochastic process is a family of RANDOM VARIABLES $\{x(t, \bullet),\ t \in \mathscr{J}\}$ from some PROBABILITY SPACE $(S, \mathbb{S}, P)$ into a STATE SPACE $(S', \mathbb{S}')$. Here, $\mathscr{J}$ is the INDEX SET of the process.

Papoulis (1984, p. 312) describes a stochastic process $x(t)$ as a family of functions.

Stochastic Resonance

A stochastic resonance is a phenomenon in which a nonlinear system is subjected to a periodic modulated signal so weak as to be normally undetectable, but it becomes detectable due to resonance between the weak deterministic signal and stochastic NOISE. The earliest definition of stochastic resonance was the maximum of the output signal strength as a function of NOISE (Bulsara and Gammaitoni 1996).

Stöhr Sequence

Let $a_1 = 1$ and define a_{n+1} to be the least INTEGER greater than a_n which cannot be written as the SUM of at most $h \geq 2$ ADDENDS among the terms $a_1, a_2, ..., a_n$. This defines the h-Stöhr sequence. The first few of these are given in the following table.

h	Sloane	h-Stöhr sequence
2	A033627	1, 2, 4, 7, 10, 13, 16, 19, 22, 25, ...
3	A026474	1, 2, 4, 8, 15, 22, 29, 36, 43, 50, ...
4	A051039	1, 2, 4, 8, 16, 31, 46, 61, 76, 91, ...
5	A051040	1, 2, 4, 8, 16, 32, 63, 94, 125, 156, ...

Stokes' Theorem

For ω a DIFFERENTIAL (K-1)-FORM with compact support on an oriented n-dimensional MANIFOLD WITH BOUNDARY M,

$$\int_M d\omega = \int_{\partial M} \omega, \tag{1}$$

where $d\omega$ is the EXTERIOR DERIVATIVE of the differential form ω. When M is a COMPACT MANIFOLD without boundary, then the formula holds with the right hand side zero.

Stokes' theorem connects to the "standard" GRADIENT, CURL, and DIVERGENCE THEOREMS by the following relations. If f is a function on $\mathbb{R}^3$,

$$grad(f) = c^{-1}\, df. \tag{2}$$

where $c : \mathbb{R}^3 \to \mathbb{R}^{3*}$ (the dual space) is the duality isomorphism between a VECTOR SPACE and its dual, given by the Euclidean INNER PRODUCT on $\mathbb{R}^3$. If f is a VECTOR FIELD on a $\mathbb{R}^3$,

$$\mathrm{div}(f) = {*d*c(f)}, \tag{3}$$

where * is the HODGE STAR operator. If f is a VECTOR FIELD on $\mathbb{R}^3$,

$$\mathrm{curl}(f) = c^{-1} {*\, dc(f)}. \tag{4}$$

With these three identities in mind, the above Stokes' theorem in the three instances is transformed into the GRADIENT, CURL, and DIVERGENCE THEOREMS respectively as follows. If f is a function on $\mathbb{R}^3$ and γ is a curve in $\mathbb{R}^3$, then

$$\int_0 \mathrm{grad}(f) \cdot dl = \int_\gamma df = f(\gamma(1)) - f(\gamma(0)), \tag{5}$$

which is the GRADIENT THEOREM. If $f : \mathbb{R}^3 \to \mathbb{R}^3$ is a VECTOR FIELD and M an embedded compact 3-manifold with boundary in $\mathbb{R}^3$, then

$$\int_{\partial M} f \cdot dA = \int_{\partial M} {*cf} = \int_M d{*cf} = \int_M \mathrm{div}(f)\, dV, \tag{6}$$

which is the DIVERGENCE THEOREM. If f is a VECTOR FIELD and M is an oriented, embedded, compact 2-MANIFOLD with boundary in $\mathbb{R}^3$, then

$$\int_{\partial M} f\, dl = \int_{\partial M} cf = \int_M dc(f) = \int_M \mathrm{curl}(f) \cdot dA, \tag{7}$$

which is the CURL THEOREM.

DE RHAM COHOMOLOGY is defined using DIFFERENTIAL K-FORMS. When N is a SUBMANIFOLD (without boundary), it represents a homology class. Two closed forms represent the same COHOMOLOGY CLASS if they differ by an EXACT FORM, $\omega_1 - \omega_2 = d\eta$. Hence,

$$\int_N \omega_1 - \omega_2 = \int_N d\eta = 0. \tag{8}$$

Therefore, the evaluation of a COHOMOLOGY CLASS on a HOMOLOGY CLASS is WELL DEFINED.

Physicists generally refer to the CURL THEOREM

$$\int_S (\nabla \times \mathbf{F}) \cdot d\mathbf{a} = \int_{\partial S} \mathbf{F} \cdot d\mathbf{s} \tag{9}$$

as Stokes' theorem.

Stolarsky-Harborth Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let $b(k)$ be the number of 1s in the BINARY expression of k. Then the number of ODD BINOMIAL COEFFICIENTS $\binom{k}{j}$ where $0 \le j \le k$ is $2^{b(k)}$ (Glaisher 1899, Fine 1947). The number of ODD elements in the first n rows of PASCAL'S TRIANGLE is

$$f(n) = \sum_{k=0}^{n-1} 2^{b(k)}. \tag{1}$$

This function is well approximated by n^θ, where

$$\theta \equiv \frac{\ln 3}{\ln 2} = 1.58496\ldots. \tag{2}$$

Stolarsky and Harborth showed that

$$0.812556 \le \liminf_{n\to\infty} \frac{f(n)}{n^\theta} < 0.812557 < \limsup_{n\to\infty} \frac{f(n)}{n^\theta} = 1. \tag{3}$$

The value

$$SH = \liminf_{n\to\infty} \frac{f(n)}{n^\theta} \tag{4}$$

is called the Stolarsky-Harborth constant.

Stolarsky's Inequality

If $0 \le g(x) \le 1$ and g is nonincreasing on the INTERVAL [0, 1], then for all possible values of a and b,

$$\int_0^1 g(x^{1/(a+b)})\,dx \ge \int_0^1 g(x^{1/a})\,dx \int_0^1 g(x^{1/b})\,dx.$$

Stomachion

A DISSECTION game similar to TANGRAMS described in fragmentary manuscripts attributed to Archimedes and was referred to as the LOCULUS OF ARCHIMEDES (Archimedes' box) in Latin texts. The word Stomachion has as its root the Greek word for stomach. The game consisted of 14 flat pieces of various shapes arranged in the shape of a square. Like TANGRAMS, the object is to rearrange the pieces to form interesting shapes.

Størmer Number

A Størmer number is a POSITIVE INTEGER n for which the largest PRIME factor p of n^2+1 is at least $2n$. Every GREGORY NUMBER t_x can be expressed uniquely as a sum of t_ns where the ns are Størmer numbers. Conway and Guy (1996) give a table of Størmer numbers reproduced below (Sloane's A005529). In a paper on INVERSE TANGENT relations, Todd (1949) gives a similar compilation.

n	p	n	p	n	p	n	p	n	p
1	2	10	101	19	181	26	677	35	613
2	5	11	61	20	401	27	73	36	1297
4	17	12	29	22	97	28	157	37	137
5	13	14	197	23	53	29	421	39	761
6	37	15	113	24	577	33	109	40	1601

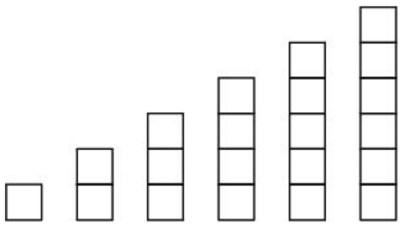
Straight Angle



An ANGLE of $180° = \pi$ RADIANS.

See also ACUTE ANGLE, ANGLE, DIGON, FULL ANGLE, OBTUSE ANGLE, REFLEX ANGLE, RIGHT ANGLE

Straight Line

LINE

Straight Polyomino

The straight polyomino of order n is the n-POLYOMINO in which all squares are placed along a line.

See also L-POLYOMINO, SKEW POLYOMINO, SQUARE POLYOMINO, T-POLYOMINO

Straightedge

An idealized mathematical object having a rigorously straight edge which can be used to draw a LINE SEGMENT. Although GEOMETRIC CONSTRUCTIONS are sometimes said to be performed with a RULER and COMPASS, the term straightedge is preferable to RULER since markings on the straightedge (usually assumed to be present on a RULER) are not allowed by the classical Greek rules.

See also COMPASS, GEOMETRIC CONSTRUCTION, GEOMETROGRAPHY, MASCHERONI CONSTANT, POLYGON, PONCELET-STEINER THEOREM, RULER, SIMPLICITY, STEINER CONSTRUCTION

Strange Attractor

An attracting set that has zero MEASURE in the embedding PHASE SPACE and has FRACTAL dimension. Trajectories within a strange attractor appear to skip around randomly.

See also CORRELATION EXPONENT, FRACTAL

Strange Loop

A phenomenon in which, whenever movement is made upwards or downwards through the levels of some hierarchical system, the system unexpectedly arrives back where it started. Hofstadter (1987) uses the strange loop as a paradigm in which to interpret paradoxes in logic (such as GRELLING'S PARADOX and RUSSELL'S PARADOX) and calls a system in which a strange loop appears a TANGLED HIERARCHY.

See also GRELLING'S PARADOX, RUSSELL'S PARADOX, TANGLED HIERARCHY

Strassen Formulas

The usual number of scalar operations (i.e., the total number of additions and multiplications) required to perform $n \times n$ MATRIX MULTIPLICATION is

$$M(n) = 2n^3 - n^2 \quad (1)$$

(i.e., n^3 multiplications and $n^3 - n^2$ additions). However, Strassen (1969) discovered how to multiply two MATRICES in

$$S(n) = 7 \cdot 7^{\lg n} - 6 \cdot 4^{\lg n} \quad (2)$$

scalar operations, where lg is the LOGARITHM to base 2, which is less than $M(n)$ for $n > 654$. For n a power of two ($n = 2^k$), the two parts of (2) can be written

$$7 \cdot 7^{\lg n} = 7 \cdot 7^{\lg 2^k} = 7 \cdot 7^k = 7 \cdot 2^{k \lg 7} = 7(2^k)^{\lg 7} = 7n^{\lg 7} \quad (3)$$

$$6 \cdot 4^{\lg n} = 6 \cdot 4^{\lg 2^k} = 6 \cdot 4^{k \lg 2} = 6 \cdot 4^k = 6(2^k)^2 = 6n^2, \quad (4)$$

so (2) becomes

$$S(2^k) = 7n^{\lg 7} - 6n^2. \quad (5)$$

Two 2×2 matrices can therefore be multiplied

$$\mathsf{C} = \mathsf{AB} \quad (6)$$

$$\begin{bmatrix} c_{11} & c_{12} \\ c_{21} & c_{22} \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} \quad (7)$$

with only

$$S(2) = 7 \cdot 2^{\lg 7} - 6 \cdot 2^2 = 49 - 24 = 25 \quad (8)$$

scalar operations (as it turns out, seven of them are multiplications and 18 are additions). Define the seven products (involving a total of 10 additions) as

$$Q_1 \equiv (a_{11} + a_{22})(b_{11} + b_{22}) \quad (9)$$

$$Q_2 \equiv (a_{21} + a_{22})b_{11} \quad (10)$$

$$Q_3 \equiv a_{11}(b_{12} - b_{22}) \quad (11)$$

$$Q_4 \equiv a_{22}(-b_{11} + b_{21}) \quad (12)$$

$$Q_5 \equiv (a_{11} + a_{12})b_{22} \quad (13)$$

$$Q_6 \equiv (-a_{11} + a_{21})(b_{11} + b_{12}) \quad (14)$$

$$Q_7 \equiv (a_{12} - a_{22})(b_{21} + b_{22}). \quad (15)$$

Then the matrix product is given using the remaining eight additions as

$$c_{11} = Q_1 + Q_4 - Q_5 + Q_7 \quad (16)$$

$$c_{21} = Q_2 + Q_4 \quad (17)$$

$$c_{12} = Q_3 + Q_5 \quad (18)$$

$$c_{22} = Q_1 + Q_3 - Q_2 + Q_6 \quad (19)$$

(Strassen 1969, Press *et al.* 1989).

Matrix inversion of a 2×2 matrix A to yield $\mathsf{C} = \mathsf{A}^{-1}$ can also be done in fewer operations than expected using the formulas

$$R_1 \equiv a_{11}^{-1} \quad (20)$$

$$R_2 \equiv a_{21}R_1 \quad (21)$$

$$R_3 \equiv R_1 a_{12} \quad (22)$$

$$R_4 \equiv a_{21}R_3 \quad (23)$$

$$R_5 \equiv R_4 - a_{22} \quad (24)$$

$$R_6 \equiv R_5^{-1} \quad (25)$$

$$c_{12} = R_3 R_6 \quad (26)$$

$$c_{21} = R_6 R_2 \quad (27)$$

$$R_7 = R_3 c_{21} \quad (28)$$

$$c_{11} = R_1 - R_7 \quad (29)$$

$$c_{22} = -R_6 \quad (30)$$

(Strassen 1969, Press *et al.* 1989). The leading exponent for Strassen's algorithm for a POWER of 2 is $\lg 7 \approx 2.808$. The best leading exponent currently known is 2.376 (Coppersmith and Winograd 1990). It has been shown that the exponent must be at least 2.

Unfortunately, Strassen's algorithm is not numerically well-behaved. It is only weakly stable, i.e., the computed result $\mathsf{C} = \mathsf{AB}$ satisfies the inequality

$$\|\mathsf{C} - \mathsf{AB}\| <= nu\|\mathsf{A}\|\ \|\mathsf{B}\| + \mathcal{O}(u^2), \quad (31)$$

where u is the unit roundoff error, while the corresponding strong stability inequality (obtained by replacing matrix norms with absolute values of the matrix elements) does not hold.

Strassman's Theorem

Let $(K, |\cdot|)$ be a complete non-ARCHIMEDEAN VALUATED FIELD, with VALUATION RING R, and let $f(X)$ be a POWER SERIES with COEFFICIENTS in R. Suppose at least one of the COEFFICIENTS is NONZERO (so that f is not identically zero) and the sequence of COEFFICIENTS converges to 0 with respect to $|\cdot|$. Then $f(X)$ has only finitely many zeros in R.

Stretch

A TRANSFORMATION characterized by an invariant line and a scale factor (one-way stretch) or two invariant lines and corresponding scale factors (two-way stretch).

See also TRANSFORMATION

Strict Gelfand Pattern

MONOTONE TRIANGLE

Strict Inequality

An INEQUALITY is strict if replacing any "less than" and "greater than" signs with equal signs never gives a true expression. For example, $a \le b$ is not strict, whereas $a < b$ is.

See also EQUALITY, INEQUALITY

Striction Curve

A NONCYLINDRICAL RULED SURFACE always has a parameterization OF THE FORM

$$\mathbf{x}(u,\ v) = \boldsymbol{\sigma}(u) + v\boldsymbol{\delta}(u), \tag{1}$$

where $|\boldsymbol{\delta}| = 1$, $\boldsymbol{\sigma}' \cdot \boldsymbol{\delta}' = 0$, and $\boldsymbol{\sigma}$ is called the striction curve of $\mathbf{x}$. Furthermore, the striction curve does not depend on the choice of the base curve. The striction and DIRECTOR CURVES of the HELICOID

$$\mathbf{x}(u,\ v) = \begin{bmatrix} 0 \\ 0 \\ bu \end{bmatrix} + av \begin{bmatrix} \cos u \\ \sin u \\ 0 \end{bmatrix} \tag{2}$$

are

$$\boldsymbol{\sigma}(u) = \begin{bmatrix} 0 \\ 0 \\ bu \end{bmatrix} \tag{3}$$

$$\boldsymbol{\delta}(u) = \begin{bmatrix} a \cos u \\ a \sin u \\ 0 \end{bmatrix}. \tag{4}$$

For the HYPERBOLIC PARABOLOID

$$\mathbf{x}(u,\ v) = \begin{bmatrix} u \\ 0 \\ 0 \end{bmatrix} + v \begin{bmatrix} 0 \\ 1 \\ u \end{bmatrix}, \tag{5}$$

the striction and DIRECTOR CURVES are

$$\boldsymbol{\sigma}(u) = \begin{bmatrix} u \\ 0 \\ 0 \end{bmatrix} \tag{6}$$

$$\boldsymbol{\delta}(u) = \begin{bmatrix} 0 \\ 1 \\ u \end{bmatrix}. \tag{7}$$

Strictly Egyptian Number

EGYPTIAN NUMBER

String

A string of length k on an ALPHABET l of m characters is an arrangement of k not necessarily distinct symbols from l. There are m^k such distinct strings. For example, the strings of length $k = 3$ on the alphabet {1, 2, 3} are {1, 1, 1}, {1, 1, 2}, {1, 2, 1}, {1, 2, 2}, {2, 1, 1}, {2, 1, 2}, {2, 2, 1}, and {2, 2, 2}. In *Mathematica*, strings of length k in the ALPHABET consisting of the members in a list l can be enumerated using the following function.

```
Strings[l_List,k_Integer?Positive] := Modu-
le[{k},
    Flatten[Outer[List, Sequence @@ Table[l,
{k}]], k-1]
  ]
```

See also ALPHABET

Strip

CRITICAL STRIP, MÖBIUS STRIP

Strombic Hexecontahedron

DELTOIDAL HEXECONTAHEDRON

Strombus

A term meaning "spinning top" in Greek which was coined by J. H. Conway by e-mail in the Polyhedron Discussion List as a term for kite-shaped quadrilaterals. Formally, a strombus is a QUADRILATERAL $ABCD$ that has AC for an axis of symmetry.

See also DIAMOND, KITE, LOZENGE, PARALLELOGRAM, QUADRILATERAL, RHOMBOID, RHOMBUS, SKEW QUADRILATERAL, STROMBUS, TRAPEZOID

Strong Convergence

Strong convergence is the type of convergence usually associated with convergence of a SEQUENCE. More formally, a SEQUENCE $\{x_n\}$ of VECTORS in a normed space (and, in particular, in an INNER PRODUCT SPACE E)is called convergent to a VECTOR x in E if

$$\|x_n - x\| \to 0 \quad \text{as } n \to \infty.$$

See also CONVERGENT SEQUENCE, INNER PRODUCT SPACE, WEAK CONVERGENCE

Strong Elliptic Pseudoprime

Let n be an ELLIPTIC PSEUDOPRIME associated with (E, P), and let $n+1=2^s k$ with k ODD and $s \geq 0$. Then n is a strong elliptic pseudoprime when either $kP \equiv 0 (\bmod n)$ or $2^r kP \equiv 0 \pmod n$ for some r with $1 \leq r < s$.

See also ELLIPTIC PSEUDOPRIME

References

Ribenboim, P. *The New Book of Prime Number Records, 3rd ed.* New York: Springer-Verlag, pp. 132–34, 1996.

Strong Frobenius Pseudoprime

A PSEUDOPRIME which obeys an additional restriction beyond that required for a FROBENIUS PSEUDOPRIME. A number n with $(n, 2a)=1$ is a strong Frobenius pseudoprime with respect to $x-a$ IFF n is a STRONG PSEUDOPRIME with respect to $f(x)$. Every strong Frobenius pseudoprime with respect to $x-a$ is an EULER PSEUDOPRIME to the base a.

Every strong Frobenius pseudoprime with respect to $f(x)=x^2-bx-c$ such that $((b^2+4c)/n)=-1$ is a STRONG LUCAS PSEUDOPRIME with parameters (b, c). Every strong Frobenius pseudoprime n with respect to x^2-bx+1 is an EXTRA STRONG LUCAS PSEUDOPRIME to the base b.

See also FROBENIUS PSEUDOPRIME

Strong Goldbach Conjecture

GOLDBACH CONJECTURE

Strong Law of Large Numbers

The sequence of variates X_i with corresponding means μ_i obeys the strong law of large numbers if, to every pair $\epsilon. \delta > 0$, there corresponds an N such that there is probability $1-\delta$ or better that for every $r > 0$, all $r+1$ inequalities

$$\frac{|S_n - m_n|}{n} < \epsilon$$

for $n=N, N+1, ..., N+r$ will be satisfied, where

$$S_n \equiv \sum_{i=1}^{n} X_n$$
$$m_n \equiv \langle S_n \rangle = \mu_1 + \ldots + \mu_n$$

(Feller 1968). Kolmogorov established that the convergence of the sequence

$$\sum \frac{\sigma_k^2}{k^2},$$

sometimes called the Kolmogorov criterion, is a sufficient condition for the strong law of large numbers to apply to the sequence of mutually independent random variables X_k with variances σ_k (Feller 1968).

See also FRIVOLOUS THEOREM OF ARITHMETIC, LAW OF LARGE NUMBERS, LAW OF TRULY LARGE NUMBERS, STRONG LAW OF SMALL NUMBERS

References

Strong Law of Small Numbers

The first law of strong numbers (Gardner 1980, Guy 1988ab, Guy 1990) states "There aren't enough small numbers to meet the many demands made of them."

The second law of strong numbers (Guy 1990) states that "When two numbers look equal, in ain't necessarily so." Guy (1988a) gives 35 examples of this statement, and 40 more in Guy (1990). For example, example 35 notes that the first few values of the interpolating polynomial $(n^4-6n^3+23n^2-18n+24)/24$ (erroneously given with a coefficient 24 instead of 23) for $n=1, 2, ...$ are 1, 2, 4, 8, 16, ..., appears to give the powers of 2 (but the continues 31, 57, 99, ...). Similar, example 41 notes the curious fact that $\lceil e^{(n-1)/2} \rceil$ for $n=0, 1, ...$ gives 1, 1, 2, 5, 8, 13, 21, 34, 55, ... (the FIBONACCI NUMBERS), although it subsequently continues 91, 149, ... (Sloane's A005181).

Strong Lucas Pseudoprime

Let $U(P, Q)$ and $V(P, Q)$ be LUCAS SEQUENCES generated by P and Q, and define

$$D \equiv P^2 - 4Q.$$

Let n be an ODD COMPOSITE NUMBER with $(n, D) = 1$, and $n - (D/n) = 2^s d$ with d ODD and $s \geq 0$, where (a/b) is the LEGENDRE SYMBOL. If

$$U_d \equiv 0 \pmod{n}$$

or

$$V_{2^r d} \equiv 0 \pmod{n}$$

for some r with $0 \leq r < s$, then n is called a strong Lucas pseudoprime with parameters (P, Q).

A strong Lucas pseudoprime is a LUCAS PSEUDOPRIME to the same base. Arnault (1997) showed that any COMPOSITE NUMBER n is a strong Lucas pseudoprime for at most 4/15 of possible bases (unless n is the PRODUCT of TWIN PRIMES having certain properties).

See also EXTRA STRONG LUCAS PSEUDOPRIME, LUCAS PSEUDOPRIME

Strong Perfect Graph Conjecture

The conjecture that a graph is PERFECT IFF neither the graph nor its complement contains an odd cycle of length at least five as an INDUCED SUBGRAPH (Golumbic 1980; Skiena 1990, p. 221).

See also PERFECT GRAPH, PERFECT GRAPH THEOREM

References

Golumbic, M. C. *Algorithmic Graph Theory and Perfect Graphs.* New York: Academic Press, 1980.
Skiena, S. *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, 1990.

Strong Pseudoprime

A strong pseudoprime to a base a is an ODD COMPOSITE NUMBER n with $n - 1 = d \cdot 2^s$ (for d ODD) for which *either*

$$a^d \equiv 1 \pmod{n} \tag{1}$$

or

$$a^{d \cdot 2^s} \equiv -1 \pmod{n} \tag{2}$$

for some $r = 0, 1, ..., s-1$ (Riesel 1994, p. 91). Note that Guy (1994, p. 27) restricts the definition of strong pseudoprimes to only those satisfying (1).

The definition is motivated by the fact that a FERMAT PSEUDOPRIME n to the base b satisfies

$$b^{n-1} - 1 \equiv 0 \pmod{n}. \tag{3}$$

But since n is ODD, it can be written $n = 2m + 1$, and

$$b^{2m} - 1 = (b^m - 1)(b^m + 1) \equiv 0 \pmod{n}. \tag{4}$$

If n is PRIME, it must DIVIDE at least one of the FACTORS, but can't DIVIDE both because it would then DIVIDE their difference

$$(b^m + 1) - (b^m - 1) = 2. \tag{5}$$

Therefore,

$$b^m \equiv \pm 1 \pmod{n}. \tag{6}$$

so write $n = 2^a t + 1$ to obtain

$$b^{n-1} - 1 = (b^t + 1)(b^t - 1)(b^{2t} + 1) \cdots \left(b^{2^{a-1} t} + 1\right). \tag{7}$$

If n DIVIDES exactly one of these FACTORS but is COMPOSITE, it is a strong pseudoprime. A COMPOSITE number is a strong pseudoprime to at most 1/4 of all bases less than itself (Monier 1980, Rabin 1980). The strong pseudoprimes provide the basis for MILLER'S PRIMALITY TEST and RABIN-MILLER STRONG PSEUDOPRIME TEST.

A strong pseudoprime to the base a is also an EULER PSEUDOPRIME to the base a (Pomerance *et al.* 1980). The strong pseudoprimes include some EULER PSEUDOPRIMES, FERMAT PSEUDOPRIMES, and CARMICHAEL NUMBERS.

The first few strong pseudoprimes to the base 2 are 2047, 3277, 4033, 4681, ... (Sloane's A001262). The number of strong pseudoprimes less than 10^3, 10^4, ... are 0, 5, 16, 46, 162, ... (Sloane's A055552). Note that Guy's (1994, p. 27) definition gives only the subset 2047, 4681, 15841, 42799, 52633, 90751, ..., giving counts inconsistent with those in Guy's table.

The strong k-pseudoprime test for $k = 2, 3, 5$ correctly identifies all PRIMES below 2.5×10^{10} with only 13 exceptions, and if 7 is added, then the only exception less than 2.5×10^{10} is 315031751. Jaeschke (1993) showed that there are only 101 strong pseudoprimes for the bases 2, 3, and 5 less than 10^{12}, nine if 7 is added, and none if 11 is added. Also, the bases 2, 13, 23, and 1662803 have no exceptions up to 10^{12}.

If n is COMPOSITE, then there is a base for which n is not a strong pseudoprime. There are therefore no "strong CARMICHAEL NUMBERS." Let ψ_k denote the smallest strong pseudoprime to all of the first k PRIMES taken as bases (i.e, the smallest ODD NUMBER for which the RABIN-MILLER STRONG PSEUDOPRIME

TEST on bases less than or equal to k fails). Jaeschke (1993) computed ψ_k from $k=5$ to 8 and gave upper bounds for $k=9$ to 11.

$$\psi_1 = 2047$$
$$\psi_2 = 1373653$$
$$\psi_3 = 25326001$$
$$\psi_4 = 3215031751$$
$$\psi_5 = 2152302898747$$
$$\psi_6 = 3474749660383$$
$$\psi_7 = 341550071728321$$
$$\psi_8 = 341550071728321$$
$$\psi_9 \leq 41234316135705689041$$
$$\psi_{10} \leq 1553360566073143205541002401$$
$$\psi_{11} = 56897193526942024370326972321$$

(Sloane's A014233). A seven-step test utilizing these results (Riesel 1994) allows all numbers less than 3.4×10^{14} to be tested.

Pomerance *et al.* (1980) have proposed a test based on a combination of STRONG PSEUDOPRIMES and LUCAS PSEUDOPRIMES. They offer a $620 reward for discovery of a COMPOSITE NUMBER which passes their test (Guy 1994, p. 28).

Strong Twin Prime Conjecture

TWIN PRIME CONJECTURE

Strongly Connected Component

A maximal SUBGRAPH of a DIRECTED GRAPH such that for every pair of vertices u, v in the SUBGRAPH, there is a directed path from u to v and a directed path from v to u. Tarjan (1972) has devised an $\mathcal{O}(n)$ algorithm for determining strongly connected components, which is implemented in *Mathematica* as `StronglyConnectedComponents[g]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``) (Skiena 1990, p. 172).

Strongly Connected Digraph

A DIRECTED GRAPH in which it is possible to reach any node starting from any other node by traversing

edges in the direction(s) in which they point. The nodes in a strongly connected digraph therefore must all have INDEGREE of at least 1. The numbers of nonisomorphic simple strongly connected digraphs on $n=1$, 2, ... nodes are 1, 1, 5, 83, 5048, 1047008, ... (Sloane's A035512).

Strongly Connected Graph

STRONGLY CONNECTED DIGRAPH

Strongly Embedded Theorem

The strongly embedded theorem identifies all SIMPLE GROUPS with a strongly 2-embedded SUBGROUP. In particular, it asserts that no SIMPLE GROUP has a strongly 2-embedded 2'-local SUBGROUP.

See also SIMPLE GROUP, SUBGROUP

Strongly Independent

An infinite sequence $\{a_i\}$ of POSITIVE INTEGERS is called strongly independent if any relation $\Sigma\, \epsilon_i a_i$, with $\epsilon_i = 0, \pm 1$, or ± 2 and $\epsilon_i = 0$ except finitely often, IMPLIES $\epsilon_i = 0$ for all i.

Strongly Triple-Free Set

TRIPLE-FREE SET

Strophoid

Let C be a curve, let O be a fixed point (the POLE), and let O' be a second fixed point. Let P and P' be points on a line through O meeting C at Q such that $P'Q = QP = QO'$. The LOCUS of P and P' is called the strophoid of C with respect to the POLE O and fixed point O'. Let C be represented parametrically by $(f(t), g(t))$, and let $O = (x_0, y_0)$ and $O' = (x_1, y_1)$. Then the equation of the strophoid is

$$x = f \pm \sqrt{\frac{(x_1 - f)^2 + (y_1 - g)^2}{1 + m^2}} \tag{1}$$

$$x = g \pm \sqrt{\frac{(x_1 - f)^2 + (y_1 - g)^2}{1 + m^2}}, \tag{2}$$

where

$$m \equiv \frac{g - y_0}{f - x_0}. \tag{3}$$

The name strophoid means "belt with a twist," and was proposed by Montucci in 1846 (MacTutor Archive). The polar form for a general strophoid is

$$r = \frac{b \sin(a - 2\theta)}{\sin(a - \theta)}. \tag{4}$$

If $a = \pi/2$, the curve is a RIGHT STROPHOID. The following table gives the strophoids of some common curves.

Curve	Pole	Fixed Point	Strophoid
line	not on line	on line	oblique strophoid
line	not on line	foot of PERPENDICULAR origin to line	RIGHT STROPHOID
CIRCLE	center	on the circumference	FREETH'S NEPHROID

See also RIGHT STROPHOID

Structural Ramsey Theory

A generalization of RAMSEY THEORY to mathematical objects in which one would not normally expect structure to be found. For example, there exists a graph with very few triangles (more precisely, a graph which can always be constructed so that there is no "cycle" of triangles which are all distinct and T_{i+1} meets T_i in at least one vertex) and such that however it is colored with r colors, one of the colors

contains a triangle. The usual proof of RAMSEY'S THEOREM gives no insight on how to prove such a result.

See also EXTREMAL GRAPH THEORY, RAMSEY'S THEOREM, RAMSEY THEORY

Structurally Stable

A MAP $\phi : M \to M$ where M is a MANIFOLD is C^r structurally stable if any C^r perturbation is TOPOLOGICALLY CONJUGATE to ϕ. Here, C^r perturbation means a FUNCTION ψ such that ψ is close to ϕ and the first r derivatives of ψ are close to those of ϕ.

See also TOPOLOGICALLY CONJUGATE

Structure

LATTICE

Structure Constant

The structure constant is defined as $i\epsilon_{ijk}$, where ϵ_{ijk} is the PERMUTATION SYMBOL. The structure constant forms the starting point for the development of LIE ALGEBRA.

See also LIE ALGEBRA, PERMUTATION SYMBOL

Structure Factor

The structure factor S_Γ of a discrete set Γ is the FOURIER TRANSFORM of δ-scatterers of equal strengths on all points of Γ,

$$S_\Gamma(k) = \int \sum_{x \in \Gamma} \delta(x' - x) e^{-2\pi i k x'}\, dx' = \sum_{x \in \Gamma} e^{-2\pi i k x}.$$

Strut

TENSEGRITY

Struve Differential Equation

The ORDINARY DIFFERENTIAL EQUATION

$$z^2 y'' + z y' + (z^2 - \nu^2) y = \frac{4\left(\frac{1}{2}z\right)^{\nu+1}}{\sqrt{\pi}\,\Gamma\left(\nu + \frac{1}{2}\right)},$$

where $\Gamma(z)$ is the GAMMA FUNCTION (Abramowitz and Stegun 1972, p. 496; Zwillinger 1997, p. 127). The solution is

$$y = aJ_\nu(z) + bY_\nu(z) + \mathscr{H}_\nu(z),$$

where $J_\nu(z)$ and $Y_\nu(z)$ are BESSEL FUNCTIONS OF THE FIRST and SECOND KINDS, and $\mathscr{H}_\nu(z)$ is a STRUVE FUNCTION (Abramowitz and Stegun 1972).

See also BESSEL FUNCTION OF THE FIRST KIND, BESSEL FUNCTION OF THE SECOND KIND, STRUVE FUNCTION

References

Abramowitz, M. and Stegun, C. A. (Eds.). *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables, 9th printing.* New York: Dover, p. 496, 1972.

Struve Function

Abramowitz and Stegun (1972, pp. 496–99) define the Struve function as

$$\mathscr{H}_\nu(z) = \left(\tfrac{1}{2}z\right)^{\nu+1} \sum_{k=0}^{\infty} \frac{(-1)^k \left(\frac{1}{2}z\right)^{2k}}{\Gamma\left(k + \frac{3}{2}\right)\Gamma\left(k + \nu + \frac{3}{2}\right)}, \tag{1}$$

where $\Gamma(z)$ is the GAMMA FUNCTION. Watson (1966, p. 338) defines the Struve function as

$$\mathscr{H}_\nu(z) \equiv \frac{2\left(\frac{1}{2}z\right)^\nu}{\Gamma\left(\nu + \frac{1}{2}\right)\Gamma\left(\frac{1}{2}\right)} \int_0^1 \left(1 - t^2\right)^{\nu - 1/2} \sin(zt)\, dt. \tag{2}$$

The series expansion is

$$\mathscr{H}_\nu(z) = \sum_{m=0}^{\infty} (-1)^m \frac{\left(\frac{1}{2}z\right)^{2m+\nu+1}}{\Gamma\left(m + \frac{3}{2}\right)\Gamma\left(\nu + m + \frac{3}{2}\right)}. \tag{3}$$

For half integer orders,

$$\mathscr{H}_{n+1/2}(z) = Y_{n+1/2}(z) + \frac{1}{\pi} \sum_{m=0}^{n} \frac{\Gamma\left(m + \frac{1}{2}\right)\left(\frac{1}{2}z\right)^{-2m+n-1/2}}{\Gamma(n + 1 - m)} \tag{4}$$

$$\mathscr{H}_{-(n+1/2)}(z) = (-1)^n J_{n+1/2}(z). \tag{5}$$

The Struve function and its derivatives satisfy

$$\mathscr{H}_{\nu-1}(z) - \mathscr{H}_{\nu+1}(z) = 2\mathscr{H}'_\nu(z) - \frac{\left(\frac{1}{2}z\right)^\nu}{\sqrt{\pi}\,\Gamma\left(\nu + \frac{3}{2}\right)}. \tag{6}$$

For integer n, the Struve function gives the solution to

$$z^2 y'' + z y' + (z^2 - n^2) y = \frac{2}{\pi} \frac{z^{n+1}}{(2n - 1)!!}, \tag{7}$$

where $n!!$ is the DOUBLE FACTORIAL.

The Struve function is built into *Mathematica* 4.0 as `StruveH[n, z]`.

MODIFIED STRUVE FUNCTION

Student's t-Distribution

A STATISTICAL DISTRIBUTION published by William Gosset in 1908. His employer, Guinness Breweries, required him to publish under a pseudonym, so he chose "Student." Given n independent measurements x_i, let

$$t \equiv \frac{\bar{x} - \mu}{s/\sqrt{n}}. \tag{1}$$

where μ is the population MEAN, $\bar{x}$ is the sample MEAN, and s is the ESTIMATOR for population STANDARD DEVIATION (i.e., the SAMPLE VARIANCE) defined by

$$s^2 \equiv \frac{1}{N-1} \sum_{i=1}^{n} (x_i - \bar{x})^2. \tag{2}$$

Student's t-distribution is defined as the distribution of the random variable t which is (very loosely) the "best" that we can do not knowing σ. If $\sigma = s$, $t = z$ and the distribution becomes the NORMAL DISTRIBUTION. As N increases, Student's t-distribution approaches the NORMAL DISTRIBUTION.

Student's t-distribution can be derived by transforming STUDENT'S Z-DISTRIBUTION using

$$z \equiv \frac{\bar{x} - \mu}{s}, \tag{3}$$

and then defining

$$t \equiv z\sqrt{n-1}. \tag{4}$$

The resulting probability and cumulative distribution functions are

$$f_r(t) = \frac{\Gamma\left[\frac{1}{2}(r+1)\right]}{\sqrt{r\pi}\,\Gamma\left(\frac{1}{2}r\right)\left(1 + \frac{t^2}{r}\right)^{(r+1)/2}} = \frac{\left(\frac{r}{r+t^2}\right)^{(1+r)/2}}{\sqrt{r}\,B\left(\frac{1}{2}r, \frac{1}{2}\right)} \tag{5}$$

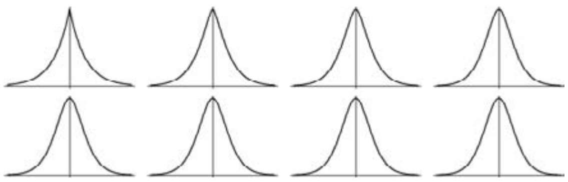
$$\begin{aligned} F_r(t) &= \int_{-\infty}^{t} \frac{\Gamma\left[\frac{1}{2}(r+1)\right]}{\sqrt{r\pi}\,\Gamma\left(\frac{1}{2}r\right)\left(1 + \frac{t'^2}{r}\right)^{(r+1)/2}}\,dt' \\ &= \frac{1}{2} + \frac{1}{2}\left[I\left(1;\ \tfrac{1}{2}r, \tfrac{1}{2}\right) - I\left(\frac{r}{r+t^2}, \tfrac{1}{2}r, \tfrac{1}{2}\right)\right] \\ &= 1 - \frac{1}{2} I\left(\frac{r}{r+t^2}, \tfrac{1}{2}r, \tfrac{1}{2}\right), \end{aligned} \tag{6}$$

where

$$r \equiv n - 1 \tag{7}$$

is the number of DEGREES OF FREEDOM, $-\infty < t < \infty$, $\Gamma(z)$ is the GAMMA FUNCTION, $B(a, b)$ is the BETA FUNCTION, and $I(z;\ a, b)$ is the REGULARIZED BETA FUNCTION defined by

$$I(z;\ a, b) = \frac{B(z;\ a, b)}{B(a, b)}. \tag{8}$$



The MEAN, VARIANCE, SKEWNESS, and KURTOSIS of Student's t-distribution are

$$\mu = 0 \tag{9}$$

$$\sigma^2 = \frac{r}{r-2} \tag{10}$$

$$\gamma_1 = 0 \tag{11}$$

$$\gamma_2 = \frac{6}{r-4}. \tag{12}$$

The CHARACTERISTIC FUNCTIONS $\phi_n(t)$ for the first few values of n are

$$\phi_1(t) = e^{-|t|} \tag{13}$$

$$\phi_2(t) = \sqrt{2}|t|K_1\left(\sqrt{2}|t|\right) \tag{14}$$

$$\phi_3(t) = e^{-\sqrt{3}|t|}\left(1+\sqrt{3}|t|\right) \tag{15}$$

$$\phi_4(t) = 2t^2 K_2(2|t|) \tag{16}$$

$$\phi_5(t) = \tfrac{1}{3}\, e^{-\sqrt{5}|t|}\left(3+3\sqrt{5}|t|+5t^2\right), \tag{17}$$

and so on, where $K_n(x)$ is a MODIFIED BESSEL FUNCTION OF THE SECOND KIND.

Beyer (1987, p. 571) gives 60%, 70%, 90%, 95%, 97.5%, 99%, 99.5%, and 99.95% confidence intervals, and Goulden (1956) gives 50%, 90%, 95%, 98%, 99%, and 99.9% confidence intervals. A partial table is given below for small r and several common confidence intervals.

r	90%	95%	97.5%	99.5%
1	3.07766	6.31371	12.7062	63.656
2	1.88562	2.91999	4.30265	9.92482
3	1.63774	2.35336	3.18243	5.84089
4	1.53321	2.13185	2.77644	4.60393
5	1.47588	2.01505	2.57058	4.03212
10	1.37218	1.81246	2.22814	3.16922
30	1.31042	1.69726	2.04227	2.74999
100	1.29007	1.66023	1.98397	2.62589
∞	1.28156	1.64487	1.95999	2.57584

The so-called $A(t|n)$ distribution is useful for testing if two observed distributions have the same MEAN. $A(t|n)$ gives the probability that the difference in two observed MEANS for a certain statistic t with n DEGREES OF FREEDOM would be smaller than the observed value purely by chance:

$$A(t|n) = \frac{1}{\sqrt{n}B\left(\frac{1}{2}, \frac{1}{2}n\right)} \int_{-t}^{t}\left(1+\frac{x^2}{n}\right)^{-(1+n)/2} dx. \tag{18}$$

Let X be a NORMALLY DISTRIBUTED random variable with MEAN 0 and VARIANCE σ^2, let Y^2/σ^2 have a CHI-SQUARED DISTRIBUTION with n DEGREES OF FREEDOM, and let X and Y be independent. Then

$$t \equiv \frac{X\sqrt{n}}{Y} \tag{19}$$

is distributed as Student's t with n DEGREES OF FREEDOM.

The noncentral Student's t-distribution is given by

$$P(x) = \frac{n^n/2^n!}{2^n e^{\lambda^2/2}(n+x^2)^{n/2}\Gamma\left(\frac{1}{2}n\right)} \times \left\{ \frac{\sqrt{2}\lambda x\, {}_1F_1\left(\frac{1}{2}n+1;\ \frac{3}{2};\ \frac{\lambda^2 z^2}{2(n+z^2)}\right)}{(n+x^2)\Gamma\left[\frac{1}{2}(n+1)\right]} + \frac{{}_1F_1\left(\frac{1}{2}(n+1);\ \frac{1}{2};\ \frac{\lambda^2 z^2}{2(n+z^2)}\right)}{\sqrt{n+x^2}\,\Gamma\left(\frac{1}{2}n+1\right)} \right\}, \tag{20}$$

where $\Gamma(z)$ is the GAMMA FUNCTION and ${}_1F_1(a;\ b;\ z)$ is a CONFLUENT HYPERGEOMETRIC FUNCTION. The MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = L\sqrt{\frac{n}{2}}\,\frac{\Gamma\left(\frac{1}{2}(n-1)\right)}{\Gamma\left(\frac{1}{2}n\right)} \tag{21}$$

$$\sigma^2 = \frac{(L^2+1)n}{n-2} - \frac{L^2 n\left[\Gamma\left(\frac{1}{2}(n-1)\right)\right]^2}{2\left[\Gamma\left(\frac{1}{2}n\right)\right]^2} \tag{22}$$

$$\gamma_1 = \frac{\gamma_1^{(n)}}{\gamma_1^{(d)}} \tag{23}$$

$$\gamma_2 = \frac{\gamma_2^{(n)}}{\gamma_2^{(d)}}. \tag{24}$$

where

$$\gamma_1^{(n)} = 2\lambda\sqrt{n}\,\Gamma\left[\tfrac{1}{2}(n-1)\right]\left\{\left[\lambda^2(2n-7)-3\right]\left[\Gamma\left(\tfrac{1}{2}n\right)\right]^2 - \lambda^2(n-2)(n-3)\left[\Gamma\left(\tfrac{1}{2}(n-1)\right)\right]^2\right\} \tag{25}$$

$$\gamma_1^{(d)} = (n-3) \times \sqrt{\frac{2n(\lambda^2+1)}{n-2} - \frac{\lambda^2 n\left[\Gamma\left(\frac{1}{2}(n-1)\right)\right]^2}{\left[\Gamma\left(\frac{1}{2}n\right)\right]^2}}\ \Gamma\left(\tfrac{1}{2}n\right)$$

$$\times\left\{\lambda^2(n-2)\left[\Gamma\left(\tfrac{1}{2}(n-1)\right]^2 - 2(\lambda^2+1)\left[\Gamma\left(\tfrac{1}{2}n\right)\right]^2\right\} \quad (26)$$

$$\gamma_2^{(n)} = 2\left\{-3\lambda^4(n-2)^2(n-3)(n-4)\left[\Gamma\left(\tfrac{1}{2}(n-1)\right)\right]^4\right.$$

$$+2^{6-2n}\lambda^2(n-2)(n-4)\left[\lambda^2(2n-7)-3\right]\pi[\Gamma(n+1)]^2$$

$$\left.-4\left[\lambda^4(n-5)-6\lambda^2-3\right](n-3)\left[\Gamma\left(\tfrac{1}{2}n\right)\right]^4\right\} \quad (27)$$

$$\gamma_2^{(d)} = (n-3)(n-4)\left\{\lambda^2(n-2)\left[\Gamma\left(\tfrac{1}{2}(n-1)\right)\right]^2\right.$$

$$\left.-2(\lambda^2+1)\left[\Gamma\left(\tfrac{1}{2}n\right)\right]^2\right\}^2. \quad (28)$$

Student's z-Distribution

The probability density function for Student's z-distribution are given by

$$f_{m,n}(z) = \frac{\Gamma\left(\frac{n}{2}\right)}{\sqrt{\pi}\,\Gamma\left(\frac{n-1}{2}\right)}\left(1+z^2\right)^{-n/2}. \quad (1)$$

Now define

$$d_{m,n}(z) \equiv \frac{|z|^{1-n}\Gamma\left(\frac{1}{2}n\right){}_2F_1\left(\frac{1}{2}(n-1),\ \frac{1}{2}n;\ \frac{1}{2}(n+1);\ -z^{-2}\right)}{2\sqrt{\pi}\,\Gamma\left[\frac{1}{2}(n+1)\right]}, \quad (2)$$

then the cumulative distribution functions is given by

$$D_{m,n}(z) = \begin{cases} d_{m,n}(z) & \text{for } z \le 0 \\ 1-d_{m,n}(z) & \text{for } z \ge 0 \end{cases} \quad (3)$$

The mean is 0, so the moments are

$$\mu_1 = 0 \quad (4)$$

$$\mu_2 = \frac{1}{n-3} \quad (5)$$

$$\mu_3 = 0 \quad (6)$$

$$\mu_4 = \frac{3}{(n-3)(n-5)}. \quad (7)$$

The mean, variance, skewness, and kurtosis are

$$\mu = 0 \quad (8)$$

$$\sigma^2 = \frac{1}{n-3} \quad (9)$$

$$\gamma_1 = 0 \quad (10)$$

$$\gamma_2 = \frac{6}{n-5}. \quad (11)$$

The characteristic function is

$$\phi(t) = \frac{2^{(3-n)/2}|t|^{(n-1)/2}K_{(1-n)/2}(|t|)}{\Gamma\left[\frac{1}{2}(n-1)\right]}, \quad (12)$$

where $K_n(z)$ is a modified Bessel function of the second kind.

Letting

$$z \equiv \frac{\bar{x}-\mu}{s}, \quad (13)$$

where x is the sample mean and μ is the population mean gives Student's t-distribution.

See also Student's t-Distribution

Study's Theorem

Given three curves ϕ_1, ϕ_2, ϕ_3 with the common group of ordinary points G (which may be empty), let their remaining groups of intersections g_{23}, g_{31}, and g_{12} also be ordinary points. If ϕ_1' is any other curve through g_{23}, then there exist two other curves ϕ_2', ϕ_3' such that the three combined curves $\phi_i\phi_i'$ are of the same order and LINEARLY DEPENDENT, each curve ϕ_k' contains the corresponding group g_{ij}, and every intersection of ϕ_i or ϕ_i' with ϕ_j or ϕ_j' lies on ϕ_k or ϕ_k'.

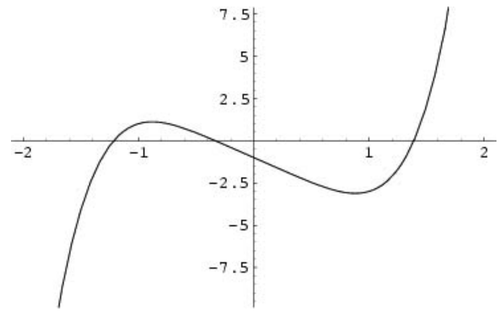
Sturm Chain

The series of STURM FUNCTIONS arising in application of the STURM THEOREM.

See also STURM FUNCTION, STURM THEOREM

Sturm Function

Given a function $f(x) \equiv f_0(x)$, write $f_1 \equiv f'(x)$ and define the Sturm functions by



$$f_n(x) = -\left\{ f_{n-2}(x) - f_{n-1}(x) \left[\frac{f_{n-2}(x)}{f_{n-1}(x)} \right] \right\}. \qquad (1)$$

where $[P(x)/Q(x)]$ is a polynomial quotient. Then construct the following chain of Sturm functions,

$$f_0 = q_0 f_1 - f_2$$
$$f_1 = q_1 f_2 - f_3$$
$$f_2 = q_2 f_3 - f_4$$
$$\vdots$$
$$f_{s-2} = q_{s-2} f_{s-1} - f_s,$$

known as a STURM CHAIN. The chain is terminated when a constant $-f_s(x)$ is obtained.

Sturm functions provide a convenient way for finding the number of real roots of an algebraic equation with real coefficients over a given interval. Specifically, the difference in the number of sign changes between the Sturm functions evaluated at two points $x = a$ and $x = b$ gives the number of real roots in the interval (a, b). This powerful result is known as the STURM THEOREM. However, when the method is applied numerically, care must be taken when computing the polynomial quotients to avoid spurious results due to roundoff error.

As a specific application of Sturm functions toward finding POLYNOMIAL ROOTS, consider the function $f_0(x) = x^5 - 3x - 1$, plotted above, which has roots -1.21465, -0.334734, $0.0802951 \pm 1.32836i$, and 1.38879 (three of which are real). The DERIVATIVE is given by $f'(x) = 5x^4 - 3$, and the STURM CHAIN is then given by

$$f_0 = x^5 - 3x - 1 \qquad (3)$$
$$f_1 = 5x^4 - 3 \qquad (4)$$
$$f_2 = \tfrac{1}{5}(12x + 5) \qquad (5)$$
$$f_3 = \tfrac{59083}{20736}. \qquad (6)$$

The following table shows the signs of f_i and the number of sign changes Δ obtained for points separated by $\Delta x = 2$.

x	f_0	f_1	f_2	f_3	Δ
-2	-1	1	-1	1	3
0	-1	-1	1	1	1
2	1	1	1	1	0

This shows that $3- = 2$ real roots lie in $(-2, 0)$, and $1- = 1$ real root lies in $(0, 2)$. Reducing the spacing to $\Delta.r = 0.5$ gives the following table.

x	f_0	f_1	f_2	f_3	Δ
-2.0	-1	1	-1	1	3
-1.5	-1	1	-1	1	3
-1.0	1	1	-1	1	2
-0.5	1	-1	-1	1	2
0.0	-1	-1	1	1	1
0.5	-1	-1	1	1	1
1.0	-1	1	1	1	1

1.5	1	1	1	1	0
2.0	1	1	1	1	0

This table isolates the three real roots and shows that they lie in the intervals (−1.5, −1.0), (−0.5, 0.0), and (1.0, 1.5). If desired, the intervals in which the roots fall could be further reduced.

The Sturm functions satisfy the following conditions:

1. Two neighboring functions do not vanish simultaneously at any point in the interval.
2. At a null point of a Sturm function, its two neighboring functions are of different signs.
3. Within a sufficiently small interval surrounding a zero point of $f_0(x)$, $f_1(x)$ is everywhere greater than zero or everywhere smaller than zero.

Sturm Theorem

The number of REAL ROOTS of an algebraic equation with REAL COEFFICIENTS whose REAL ROOTS are simple over an interval, the endpoints of which are not ROOTS, is equal to the difference between the number of sign changes of the STURM CHAINS formed for the interval ends.

See also STURM CHAIN, STURM FUNCTION

Sturmian Separation Theorem

Let $\mathsf{A}_r = a_{ij}$ be a SEQUENCE of N SYMMETRIC MATRICES of increasing order with $i, j = 1, 2, ..., r$ and $r = 1, 2, ..., N$. Let $\lambda_k(\mathsf{A}_r)$ be the kth EIGENVALUE of A_r for $k = 1, 2, ..., r$, where the ordering is given by

$$\lambda_1(\mathsf{A}_r) \geq \lambda_2(\mathsf{A}_r) \geq \ldots \geq \lambda_r(\mathsf{A}_r).$$

Then it follows that

$$\lambda_{k+1}(\mathsf{A}_{i+1}) \leq \lambda_k(\mathsf{A}_i) \leq \lambda_k(\mathsf{A}_{i+1}).$$

Sturmian Sequence

If a SEQUENCE has the property that the BLOCK GROWTH function $B(n) = n + 1$ for all n, then it is said to have minimal block growth, and the sequence is called a Sturmian sequence. An example of this is the sequence arising from the SUBSTITUTION MAP

$$0 \to 01$$

$$1 \to 0$$

yielding $0 \to 01 \to 010 \to 01001 \to 01001010 \to \ldots$, which gives us the Sturmian sequence 01001010....

STURM FUNCTIONS are sometimes also said to form a Sturmian sequence.

See also STURM FUNCTION, STURM THEOREM

Sturm-Liouville Equation

A second-order ORDINARY DIFFERENTIAL EQUATION

$$\frac{d}{dx}\left[p(x)\frac{dy}{dx}\right] + [\lambda w(x) - q(x)]y = 0,$$

where λ is a constant and $w(x)$ is a known function called either the density or WEIGHTING FUNCTION. The solutions (with appropriate boundary conditions) of λ are called EIGENVALUES and the corresponding $u_\lambda(x)$ EIGENFUNCTIONS. The solutions of this equation satisfy important mathematical properties under appropriate boundary conditions (Arfken 1985).

See also ADJOINT, SELF-ADJOINT

Subdiagonal

The subdiagonal of a SQUARE MATRIX is the set of elements directly under the elements comprising the DIAGONAL. For example, in the following matrix, the diagonal elements are denoted d_i and the subdiagonals are denoted s_i,

$$\begin{bmatrix} d_1 & a_{12} & a_{13} & \cdots & a_{1n} \\ s_1 & d_2 & a_{23} & \ddots & a_{2n} \\ a_{31} & s_2 & d_3 & \ddots & a_{3n} \\ \vdots & \ddots & \ddots & \ddots & \ddots \\ a_{n1} & a_{n2} & a_{n3} & \cdots & d_n \end{bmatrix}.$$

See also CANONICAL BOX MATRIX, DIAGONAL, SUPERDIAGONAL, TRIDIAGONAL MATRIX

References

Faddeeva, V. N. *Computational Methods of Linear Algebra.* New York: Dover, p. 50, 1958.

Subfactorial

The number of PERMUTATIONS of n objects in which no object appears in its natural place (i.e., the number of so-called "DERANGEMENTS").

$$!n \equiv n! \sum_{k=0}^{n} \frac{(-1)^k}{k!} \tag{1}$$

or

$$!n \equiv \left[\frac{n!}{e}\right]. \tag{2}$$

where $k!$ is the usual FACTORIAL and $[x]$ is the NINT function. The first few values are $!1 = 0$, $!2 = 1$, $!3 = 2$, $!4 = 9$, $!5 = 44$, $!6 = 265$, $!7 = 1854$, $!8 = 14833$, ... (Sloane's A000166). For example, the only DERANGEMENTS of $\{1, 2, 3\}$ are $\{2, 3, 1\}$ and $\{3, 1, 2\}$, so $!3 = 2$. Similarly, the DERANGEMENTS of $\{1, 2, 3, 4\}$ are $\{2, 1, 4, 3\}$, $\{2, 3, 4, 1\}$, $\{2, 4, 1, 3\}$, $\{3, 1, 4, 2\}$, $\{3, 4, 1, 2\}$, $\{3, 4, 2, 1\}$, $\{4, 1, 2, 3\}$, $\{4, 3, 1, 2\}$, and $\{4, 3, 2, 1\}$, so $!4 = 9$. The only prime subfactorial is $!3 = 2$.

The subfactorials are also called the RENCONTRES NUMBERS and satisfy the RECURRENCE RELATIONS

$$!n = n \cdot !(n-1) + (-1)^n \tag{3}$$

$$!(n+1) = n[!n + !(n-1)]. \tag{4}$$

The subfactorial can be considered a special case of a restricted ROOKS PROBLEM.

The only number equal to the sum of subfactorials of its digits is

$$148{,}349 = !1 + !4 + !8 + !3 + !4 + !9 \tag{5}$$

(Madachy 1979).

Subfield

If a subset S of the elements of a FIELD F satisfies the FIELD AXIOMS with the same operations of F, then S is called a subfield of F. In a FINITE FIELD of ORDER p^n, with p a prime, there exists a subfield of ORDER p^m for every m DIVIDING n.

See also EXTENSION FIELD, FIELD, PRIME SUBFIELD, SUBMANIFOLD, SUBSPACE

Subgraph

A GRAPH G' whose VERTICES and EDGES form subsets of the VERTICES and EDGES of a given GRAPH G. If G' is a subgraph of G, then G is said to be a SUPERGRAPH of G'.

See also GRAPH, INDUCED SUBGRAPH, SUPERGRAPH, SUBTREE, ULAM'S CONJECTURE

References

Harary, F. *Graph Theory.* Reading, MA: Addison-Wesley, p. 11, 1994.

Subgroup

A subset H of GROUP elements of a group G that satisfies the four GROUP requirements. "H is a subgroup of G" is written $H \subset G$. The ORDER of any

subgroup of a GROUP of ORDER h must be a DIVISOR of h.

See also CARTAN SUBGROUP, COMPOSITION SERIES, FITTING SUBGROUP, GROUP, NORMAL SUBGROUP

Subharmonic Function

Let $U \subseteq C$ be an OPEN SET and f a real-valued continuous function on U. Suppose that for each CLOSED DISK $D(P, r) \subseteq U$ and every real-valued HARMONIC FUNCTION h defined on a NEIGHBORHOOD of $D(P, r)$ which satisfies $f \leq h$ on $\partial D(P, r)$, it holds that $f \leq h$ on the OPEN DISK $D(P, r)$. Then f is said to be subharmonic on U (Krantz 1999, p. 99).

1. If f_1, f_2 are subharmonic on U, then so is $f_1 + f_2$.
2. If f_1 is subharmonic on U and $a > 0$ is a constant, than af_1 is subharmonic on U.
3. If f_1, f_2 are subharmonic on U, then $\max\{f_1(z), f_2(z)\}$ is also subharmonic on U.

See also BARRIER, HARMONIC FUNCTION

Submanifold

A C^∞ (infinitely differentiable) MANIFOLD is said to be a submanifold of a C^∞ MANIFOLD M' if M is a SUBSET of M' and the IDENTITY MAP of M into M' is an EMBEDDING.

See also EMBEDDING, MANIFOLD, SUBFIELD, SUBSPACE

Submatrix

submatrices

A $p \times q$ submatrix of an $m \times n$ MATRIX (with $p \leq m$, $n \leq q$) is a $p \times q$ MATRIX formed by taking a block of the entries of this size from the original matrix.

See also MATRIX

Submersion

A submersion is a SMOOTH MAP $f : M \to N$ when

$$\dim M \geq \dim N,$$

given that the DIFFERENTIAL, or JACOBIAN, is SURJECTIVE at every x in M. The basic example of a submersion is the canonical submersion α of $\mathbb{R}^n$ onto $\mathbb{R}^k$ when $n \geq k$,

$$\alpha(x_1, \ldots, x_n) = (x_1, \ldots, x_k).$$

In fact, if f is a submersion, then it is possible to find coordinates around x in M and coordinates around $f(x)$ in N such that f is the canonical submersion written in these coordinates. For example, consider the submersion of $\mathbb{R}^2 - \{(0, 0)\}$ onto the circle $\mathbb{S}^1$, given by $f(x, y) = (x, y)/\sqrt{x^2 + y^2}$.

See also IMMERSION, RIEMANNIAN SUBMERSION

Submodule

A MODULE over a RING that is contained in and has the same addition as another MODULE over the same RING.

See also MODULE

Subnormal

If the LEXIS RATIO $L < 1$, a set of trials are said to be subnormal.

See also LEXIS RATIO, SUBNORMAL SUBGROUP, SUPERNORMAL

Subnormal Subgroup

L is a subnormal SUBGROUP of H if there is a "normal series" (in the sense of Jordan-Holder) from L to H.

Suborder Function

A special case of the generalized MULTIPLICATIVE ORDER function taken with respect to the PRIMITIVE ROOTS -1 and 1. This function is denoted $\text{sord}_n(a)$ and is implemented in *Mathematica* as `MultiplicativeOrder[a, n, {-1, 1}]`.

See also MULTIPLICATIVE ORDER

Subordinate Norm

NATURAL NORM

Subresultant

Subresultants for a few simple pairs of polynomials include

$$S(x-a,\ x-b)=\{a-b,\ 1\}$$

$$S((x-a)(x-b),\ x-c)=\{(a-c)(b-c),\ 1\}$$

$$S((x-a)(x-b),\ (x-c)(x-d))$$
$$=\{(a-c)(b-c)(a-d)(b-d),\ a+b-c-d,\ 1\}.$$

The principal subresultants of two polynomials can be computed using the *Mathematica* command `Subresultants`[*poly1*, *poly2*, *var*]. The first k subresultants of two polynomials p_1 and p_2, both with leading coefficient one, are zero when p_1 and p_2 have k common roots.

Subring

A subring of a RING R is a SUBGROUP of R that is CLOSED under multiplication.

See also RING, SUBGROUP

References

Dummit, D. S. and Foote, R. M. *Abstract Algebra, 2nd ed.* Englewood Cliffs, NJ: Prentice-Hall, p. 230, 1998.

Subscript

A quantity displayed below the normal line of text (and generally in a smaller point size), as the "i" in a_i, is called a subscript. Subscripts are commonly used to indicate indices (a_{ij} is the entry in the ith row and jth column of a MATRIX A), partial differentiation (y_x is an abbreviation for $\partial y/\partial x$), and a host of other operations and notations in mathematics.

See also SUPERSCRIPT

Subselfsimilar Set

Giving a set $F=\{f_1,\ f_2,\ \ldots,\ f_n\}$ of contracting similitudes of $\mathbb{R}^r$, the closed set E is said to be subselfsimilar for F if

$$E\subset\bigcup_{i=1}^{n} f_i(E)$$

(Falconer 1995, Duvall and Keesling 1999).

References

Duvall, P. and Keesling, J. The Hausdorff Dimension of the Boundary of the Lévy Dragon. 22 Jul 1999. http://xxx.lanl.gov/abs/math.DS/9907145/.

Subsequence

A subsequence of a SEQUENCE $S=\{x_i\}_{i=1}^n$ is a derived sequence $\{y_i\}_{i=1}^N=\{x_{i+j}\}$ for some $j\geq 0$ and $N\leq n-j$. More generally, the word subsequence is sometimes used to mean a sequence derived from a sequence S by discarding some of its terms.

See also LOWER-TRIMMED SUBSEQUENCE, UPPER-TRIMMED SUBSEQUENCE

Subset

A portion of a SET. B is a subset of A (written $B\subseteq A$) IFF every member of B is a member of A. If B is a PROPER SUBSET of A (i.e., a subset other than the set itself), this is written $B\subset A$. If B is not a subset of A, this is written $B\nsubseteq A$. (The notation $B\not\subset A$ is generally not used, since $B\nsubseteq A$ automatically means that B and A cannot be the same.)

The set of subsets of a set S is called the POWER SET of S, and a SET of n elements has 2^n subsets (including both the set itself and the EMPTY SET). This follows from the fact that the total number of distinct k-SUBSET on a set of n elements is given by the BINOMIAL SUM

$$\sum_{k=0}^{n}\binom{n}{k}=2^n.$$

For sets of $n=1,\ 2,\ \ldots$ elements, the numbers of subsets are therefore 2, 4, 8, 16, 32, 64, ... (Sloane's A000079). For example, the set $\{1\}$ has the two subsets $\varnothing$ and $\{1\}$. Similarly, the set $\{1,\ 2\}$ has subsets $\varnothing$ (the EMPTY SET, $\{1\}$, $\{2\}$, and $\{1,\ 2\}$. The subsets (i.e., POWER SET) of a given set can be found using `Subsets`[*list*] in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

Subspace

Let $\mathbb{V}$ be a REAL VECTOR SPACE (e.g., the real continuous functions $C(I)$ on a CLOSED INTERVAL I, 2-D EUCLIDEAN SPACE $\mathbb{R}^2$, the twice differentiable real functions $C^{(2)}(I)$ on I, etc.). Then $\mathbb{W}$ is a real SUBSPACE of $\mathbb{V}$ if $\mathbb{W}$ is a SUBSET of $\mathbb{V}$ and, for every $\mathrm{w}_1, \mathrm{w}_1 \in \mathbb{W}$ and $t \in \mathbb{R}$ (the REALS), $\mathrm{w}_1 + \mathrm{w}_2 \in \mathbb{W}$ and $t\mathrm{w}_1 \in \mathbb{W}$. Let (H) be a homogeneous system of linear equations in $x_1, ..., x_n$. Then the SUBSET S of $\mathbb{R}^n$ which consists of all solutions of the system (H) is a subspace of $\mathbb{R}^n$.

More generally, let F_q be a FIELD with $q = p^\alpha$, where p is PRIME, and let $F_{q,n}$ denote the n-D VECTOR SPACE over F_q. The number of k-D linear subspaces of $F_{q,n}$ is

$$N(F_{q,n}) = \binom{n}{k}_q,$$

where this is the q-BINOMIAL COEFFICIENT (Aigner 1979, Exton 1983). The asymptotic limit is

$$N(F_{q,n}) = \begin{cases} c_e q^{n^2/4}[1+o(1)] & \text{for } n \text{ even} \\ c_o q^{n^2/4}[1+o(1)] & \text{for } n \text{ odd,} \end{cases}$$

where

$$c_e = \frac{\sum_{k=-\infty}^{\infty} q^{-k^2}}{\prod_{j=1}^{\infty}(1-q^{-j})}$$

$$c_o = \frac{\sum_{k=-\infty}^{\infty} q^{-(k+1/2)^2}}{\prod_{j=1}^{\infty}(1-q^{-j})}$$

(Finch). The case $q = 2$ gives the q-ANALOG of the WALLIS FORMULA.

Substitution Group

PERMUTATION GROUP

Substitution Map

A MAP which uses a set of rules to transform elements of a sequence into a new sequence using a set of rules which "translate" from the original sequence to its transformation. For example, the substitution map $\{1 \to 0,\ 0 \to 11\}$ would take 10 to 011.

See also GOLDEN RATIO, MORSE-THUE SEQUENCE, STRING REWRITING, THUE CONSTANT

Substitution Tensor

KRONECKER DELTA, PERMUTATION SYMBOL, PERMUTATION TENSOR

Subtend

Given a geometric object O in the PLANE and a point P, let A be the ANGLE from one edge of O to the other with VERTEX at P. Then O is said to subtend an ANGLE A from P.

See also ANGLE, VERTEX ANGLE

Subtraction

Subtraction is the operation of taking the DIFFERENCE $x - y$ of two numbers x and y. Here, x is called the MINUEND, y is called the SUBTRAHEND, and the symbol between the x and y is called the MINUS SIGN. The expression "$x - y$" is read "x MINUS y." Subtraction is the inverse of ADDITION, so $x + y - y = x - y + y = x$.

The subtraction of a number from itself gives 0, while the subtraction of a real number from a smaller real number gives a negative real number. Subtraction of real numbers can be naturally extended to complex numbers.

See also ADDITION, DIVISION, MINUEND, MINUS, MINUS SIGN, MULTIPLICATION, SUBTRAHEND

Subtrahend

A quantity which is subtracted from another (the MINUEND).

See also MINUEND, SUBTRACTION

Subtree

A TREE G' whose VERTICES and EDGES form subsets of the VERTICES and EDGES of a given TREE G.

See also SUBGRAPH, TREE

Subvariety

See also ALGEBRAIC VARIETY

Succeeds

The relationship x succeeds (or FOLLOWS) y is written $x \succ y$. The relation x succeeds or is equal to y is written $x \succeq y$.

See also PRECEDES

Successes

DIFFERENCE OF SUCCESSES

Successor

For any ORDINAL NUMBER α, the successor of α is $\alpha \cup \{\alpha\}$ (Ciesielski 1997, p. 46). The successor of an ordinal number α is therefore the next ordinal, $\alpha + 1$.

See also LIMIT ORDINAL, ORDINAL NUMBER

Sufficient

A CONDITION which, if true, guarantees that a result is also true. (However, the result may also be true if the CONDITION is not met.) If a CONDITION is both NECESSARY and SUFFICIENT, then the result is said to be true IFF (the CONDITION holds.

For example, the condition that a decimal number n end in the DIGIT 2 is a sufficient but not NECESSARY condition that n be EVEN.

Suitable Number

IDONEAL NUMBER

Sultan's Dowry Problem

A sultan has granted a commoner a chance to marry one of his n daughters. The commoner will be presented with the daughters one at a time and, when each daughter is presented, the commoner will be told the daughter's dowry (which is fixed in advance). Upon being presented with a daughter, the commoner must immediately decide whether to accept or reject her (he is not allowed to return to a previously rejected daughter). However, the sultan will allow the marriage to take place only if the commoner picks the daughter with the overall highest dowry. Then what is the commoner's best strategy, assuming he knows nothing about the distribution of dowries (B. Elbows)?

Since the commoner knows nothing about the distribution of the dowries, the best strategy is to wait until a certain number x of daughters have been presented, then pick the highest dowry thereafter. The exact number to skip is determined by the condition that the odds that the highest dowry has already been seen is just greater than the odds that it remains to be seen *and that if it is seen it will be picked.* This amounts to finding the smallest x such that

$$\frac{x}{n} \geq \frac{x}{n}\left(\frac{1}{x+1} + \ldots + \frac{1}{n-1}\right). \tag{1}$$

Computing the sum analytically gives the solution as the smallest x such that

$$H_x \geq H_n - 1, \tag{2}$$

where H_n is a HARMONIC NUMBER. Solving

$$H_x = H_n - 1 \tag{3}$$

numerically and taking the CEILING FUNCTION $\lceil x \rceil$ then gives the solutions 0, 1, 1, 2, 2, 2, 3, 3, 3, 4, 4, 5, 5, 5, ... (Sloane's A054382) for n = 1, 2, ... daughters.

The problem is most commonly stated with $n = 100$ daughters, which gives the result that the commoner should wait until he has seen 37 of the daughters, then pick the first daughter with a dowry that is bigger than any preceding one. With this strategy, his odds of choosing the daughter with the highest dowry are surprisingly high: about 37% (B. Elbows; Honsberger 1979, pp. 104–10, Mosteller 1987).

Sum

A sum is the result of an ADDITION. For example, adding 1, 2, 3, and 4 gives the sum 10, written

$$1+2+3+4=10. \quad (1)$$

The numbers being summed are called ADDENDS, or sometimes SUMMANDS. The summation operation can also be indicated using a capital sigma with upper and lower limits written above and below, and the index indicated below. For example, the above sum could be written

$$\sum_{k=1}^{4} k=10. \quad (2)$$

A sum

$$\sum_{i=1}^{n} a_i \quad (3)$$

in which each term a_i is given by some fixed rule (i.e., $\{a_i\}_{i=1}^n$ is a well defined SEQUENCE) is called a SERIES, and if the number of terms n is infinite, the sum is called an INFINITE SERIES. A sum of the form

$$\sum_{k=1}^{n} r^k \quad (4)$$

is called a GEOMETRIC SERIES.

The general finite POWER SUM

$$\sum_{k=1}^{n} k^p \quad (5)$$

can be given by the expression

$$\sum_{k=1}^{n} k^p=\frac{(B+n+1)^{[p+1]}-B^{[p+1]}}{p+1}, \quad (6)$$

which is equivalent to FAULHABER'S FORMULA, where the NOTATION $B^{[k]}$ means the quantity in question is raised to the appropriate POWER k and all terms OF THE FORM B^m are replaced with the corresponding BERNOULLI NUMBERS B_m.

NICOMACHUS'S THEOREM gives as curious expression for the POWER SUM $\Sigma_{k=1}^n k^3$.

Other analytic sums include

$$\left(\sum_{k=0}^{n} x^k\right)^p =\frac{1}{(p-1)!}\sum_{k=0}^{np}\frac{(n-|n-k|+p-1)!}{(n-|n-k|)!}x^k \quad (7)$$

for $p=1,\ 2$

$$\left(\sum_{n=0}^{\infty} a_n x^n\right)^2=\sum_{n=0}^{\infty} a_n^2 x^{2n}+2\sum_{\substack{n=1\\ i+j=n\\ i<j}}^{\infty} a_i a_j x^n, \quad (8)$$

and

$$\begin{aligned}\sum xy &= x_1y_1+x_1y_2+\ldots+x_2y_1+x_2y_2+\ldots\\ &=(x_1+x_2+\ldots)y_1+(x_1+x_2+\ldots)y_2\\ &=\left(\sum x\right)(y_1+y_2+\ldots)=\sum x\sum y,\end{aligned} \quad (9)$$

so

$$\sum_{i=1}^{m}\sum_{j=1}^{n} x_i x_j=\left(\sum_{i=1}^{m} x_i\right)\left(\sum_{j=1}^{n} y_j\right). \quad (10)$$

$$\sum_{j=0}^{n} jx^j=\frac{nx^{n+2}-(n+1)x^{n+1}+x}{(x-1)^2} \quad (11)$$

$$\sum_{j=1}^{n}\frac{x_j^r}{\prod_{\substack{k=1\\ k\neq j}}^{n}(x_j-x_k)}=\begin{cases}0 & \text{for } 0\le r<n-1\\ 1 & \text{for } r=n-1\\ \sum_{j=1}^n x_j & \text{for } r=n\end{cases} \quad (12)$$

$$\sum_{k=1}^{n}\frac{\prod_{\substack{r=1\\ r\neq k}}^{n}(x+k-r)}{\prod_{\substack{r=1\\ r\neq k}}^{n}(k-r)}=1 \quad (13)$$

$$(n+1)\sum_{m=1}^{n} m^k=\sum_{m=1}^{n}\left[m^{k+1}+\sum_{p=1}^{n}\left(\sum_{m=1}^{p} m^k\right)\right]. \quad (14)$$

To minimize the sum of a set of squares of numbers $\{x_i\}$ about a given number x_0

$$S\equiv\sum_i (x_i-x_0)^2=\sum_i x_i^2-2x_0\sum x_i+Nx_0^2. \quad (15)$$

take the DERIVATIVE.

$$\frac{d}{dx_0}S=-2\sum_i x_i+2Nx_0=0. \quad (16)$$

Solving for x_0 gives

$$x_0\equiv\bar{x}=\frac{1}{N}\sum_i x_i. \quad (17)$$

so S is minimized when x_0 is set to the MEAN.

Sum of Squares Function

The number of representations of n by k squares, distinguishing signs and order, is denoted $r_k(n)$. For example, consider the number of ways of representing 5 as the sum of two squares.

$$5 = (-2)^2 + (-1)^2 = (-2)^2 + 1^2 = 2^2 + (-1)^2$$
$$= 2^2 + 1^2 = (-1)^2 + (-2)^2 = (-1)^2 + 2^2$$
$$= 1^2 + (-2)^2 = 1^2 + 2^2 \quad (1)$$

so $r_2(5) = 8$. The *Mathematica* function SumOfSquaresR[k, n] in the *Mathematica* add-on package NumberTheory'NumberTheoryFunctions' (which can be loaded with the command < <NumberTheory') gives $r_k(n)$.

The function $r_2(n)$ is often written simply as $r(n)$, and is intimately connected with the LEIBNIZ SERIES and with GAUSS'S CIRCLE PROBLEM (Hilbert and Cohn-Vossen 1999, pp. 27–9). It is also given by the inverse Möbius transform of the sequence $b_{2n} = 0$ and $b_{2n+1} = 4(-1)^n$ (Sloane and Plouffe 1995, p. 22). The average order of $r(n)$ is π, but the normal order is 0 (Hardy 1999, p. 55).

Jacobi gave analytic expressions for $r_k(n)$ for the cases $k = 2$, 4, 6, and 8 (Hardy 1999, p. 132). The cases $k = 2$, 4, and 6 were found by equating COEFFICIENTS of the JACOBI THETA FUNCTIONS $\vartheta_3(x)$, $\vartheta_3^2(x)$, and $\vartheta_3^4(x)$. The solutions for $k = 10$ and 12 were found by Liouville and Eisenstein, and Glaisher (1907) gives a table of $r_k(n)$ for $k = 2s = 18$. $r_3(n)$ was found as a finite sum involving quadratic reciprocity symbols by Dirichlet. $r_5(n)$ and $r_7(n)$ were found by Eisenstein, Smith, and Minkowski.

A POSITIVE INTEGER can be represented as the sum of two squares IFF each of its prime factors of the form $k + 3$ occurs as an even power, as first established by Euler in 1738. In LAGRANGE'S FOUR-SQUARE THEOREM, Lagrange proved that every POSITIVE INTEGER can be written as the SUM of at most four SQUARES. where 4 may be reduced to 3 except for numbers OF THE FORM $4^n(8k+7)$, as proved by Legendre in 1798 (Nagell 1951, p. 194; Wells 1986, pp. 48 and 56; Hardy 1999, p. 12; Savin 2000).

$r(n) = r_2(n)$ is 0 whenever n has a PRIME divisor OF THE FORM $4k + 3$ to an ODD POWER; it doubles upon reaching a new PRIME OF THE FORM $4k + 1$. It is given explicitly by

$$r_2(n) = 4 \sum_{d=1,\ 3,\ \ldots|n} (-1)^{(d-1)/2} \quad (2)$$
$$= 4[d_1(n) - d_3(n)] \quad (3)$$
$$= 4 \sum_{d|n} \sin\left(\tfrac{1}{2}\pi d\right), \quad (4)$$

where $d_k(n)$ is the number of DIVISORS of n OF THE FORM $4m + k$ (Hilbert and Cohn-Vossen 1999, pp. 37–8; Hardy 1999, p. 12). The first few values are 4, 4, 0, 4, 8, 0, 0, 4, 4, 8, 0, 0, 8, 0, 0, 4, 8, 4, 0, 8, 0, 0, 0, 0, 12, 8, 0, 0, ... (Sloane's A004018). $r(n)$ obeys the unexpected identities

$$\sum_{n=0}^{\infty} \frac{r(n)}{\sqrt{n+a}} e^{-2\pi\sqrt{(n+a)b}} = \sum_{n=0}^{\infty} \frac{r(n)}{\sqrt{n-b}} e^{-2\pi\sqrt{(n+b)a}} \quad (5)$$

for $\Re[\sqrt{a}]$, $\Re\left[\sqrt{b}\right] > 0$,

$$\sum_{0 \le n \le x} \frac{r(n)}{\sqrt{x-n}} = 2\pi\sqrt{x} + \sum_{n=1}^{\infty} \frac{r(n)}{\sqrt{n}} \sin\left(2\pi\sqrt{nx}\right) \quad (6)$$

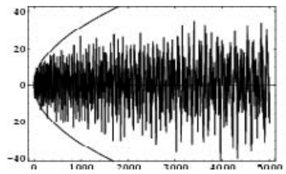
and

$$\sum_{0 \le n \le x} r(n) = \pi x + \sqrt{x} \sum_{n=1}^{\infty} \frac{r(n)}{\sqrt{n}} J_1\left(2\pi\sqrt{nx}\right) \quad (7)$$

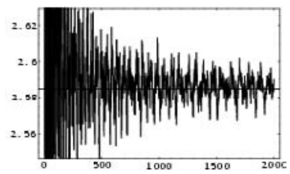
(Hardy 1999, p. 82).

The first few values of the summatory function

$$R(n) = \sum_{k=1}^{n} r_2(n) \quad (8)$$



are 0, 4, 8, 8, 12, 20, 20, 20, 24, 28, 36, ... (Sloane's A014198). Shanks (1993) defines instead $R'(n) = 1 + R(n)$, with $R'(0) = 1$. A LAMBERT SERIES for $r_2(n)$ is



$$\sum_{n=1}^{\infty} \frac{4(-1)^{n+1}x^n}{1-x^n} = \sum_{n=1}^{\infty} r_2(n)x^n \quad (9)$$

(Hardy and Wright 1979). Explicit values of $R'(n)$ for several powers of 10 are given in the following table (Mitchell 1966; Shanks 1993, pp. 165 and 234).

n	$R'(10^n)$
0	5
1	37

2	317
3	3149
4	31417
5	314197
6	3141549
8	314159053
10	31415925457
12	3141592649625
14	31415926535058

Asymptotic results include

$$\sum_{k=1}^{n} r_2(k) = \pi n + \mathcal{O}\left(\sqrt{n}\right) \quad (10)$$

$$\sum_{k=1}^{n} \frac{r_2(k)}{k} = K + \pi \ln n + \mathcal{O}\left(n^{-1/2}\right), \quad (11)$$

where K is a constant known as the SIERPINSKI CONSTANT. The left plot above shows

$$\left[\sum_{k=1}^{n} r_2(k)\right] - \pi n, \quad (12)$$

with $\pm\sqrt{n}$ illustrated by curved envelope, and the right plot shows

$$\left[\sum_{k=1}^{n} \frac{r_2(k)}{k}\right] - \pi \ln n, \quad (13)$$

with the value of K indicated as the solid horizontal line.

The number of solutions of

$$x^2 + y^2 + z^2 = n \quad (14)$$

for a given n without restriction on the signs or relative sizes of x, y, and z is given by $r_3(n)$. Gauss proved that if n is SQUAREFREE and $n > 4$, then

$$r_3(n) = \begin{cases} 24h(-n) & \text{for } n \equiv 3 \pmod 8 \\ 12h(-4n) & \text{for } n \equiv 1,\ 2,\ 5,\ 6 \pmod 8 \\ 0 & \text{for } n \equiv 7 \pmod 8 \end{cases} \quad (15)$$

(Arno 1992), where $h(x)$ is the CLASS NUMBER of x.

Additional higher-order identities are given by

$$r_4(n) = 8 \sum_{d|n} d = 8\sigma(n) \quad (16)$$

$$= 24 \sum_{d=1,\ 3,\ \ldots|n} d \quad (17)$$

$$= 24\sigma_0(n) \quad (18)$$

$$r_s(n) - 16 \sum_{d|n} (-1)^{n+d} d^3 \quad (19)$$

$$r_{16}(n) = -\tfrac{32}{3}(-1)^n [\sigma'_1(d) + \sigma'_3(d) + \sigma'_5(d)]$$

$$= (-1)^n \tfrac{256}{3} \sum_{k=1}^{n-1} [\sigma'_1(k)\sigma'_5(n-k) - \sigma'_3(k)\sigma'_3(n-k)] \quad (20)$$

$$r_{10}(n) = \tfrac{4}{5}[E'_4(n) + 16E'_4(n) + 8\chi_4(n)] \quad (21)$$

$$r_{24}(n) = \rho_{24}(24) + \tfrac{128}{691}\left[(-1)^{n-1} 259\tau(n) - 512\tau\left(\tfrac{1}{2}n\right)\right], \quad (22)$$

where

$$\sigma'_r(n) = \sum_{d|n} (-1)^{n+n/d} d^r \quad (23)$$

$$E_4(n) = \sum_{d=1,\ 3,\ \ldots|n} (-1)^{(d-1)/2} d^4 \quad (24)$$

$$E'_4(n) = \sum_{d'=1,\ 3,\ \ldots|n} (-1)^{(d'-1)/2} d^4 \quad (25)$$

$$\chi_4(n) = \tfrac{1}{4} \sum_{a^2+b^2=n} (a+bi)^4, \quad (26)$$

$d' = n/d$, $d_k(n)$ is the number of divisors of n OF THE FORM $4m+k$, $\rho_{24}(n)$ is a SINGULAR SERIES, $\sigma(n)$ is the DIVISOR FUNCTION, $\sigma_0(n)$ is the DIVISOR FUNCTION of order 0 (i.e., the number of DIVISORS), and τ is the TAU FUNCTION. $r_{24}(n)$ may also be written in the alternate form

$$r_{24}(n) = (-1)^n \tfrac{16}{9}(17\sigma''_3(d) + 8\sigma''_5(d) + 2\sigma''_7(d)$$

$$+ (-1)^n \tfrac{512}{9} \sum_{k=1}^{n-1} [\sigma''_3(k)\sigma''_7(n-k) - \sigma''_5(d)\sigma''_5(n-k)], \quad (27)$$

where

$$\sigma''_r(n) = \sum_{d|n} (-1)^n d^r. \quad (28)$$

Similar expressions exist for larger EVEN k, but they quickly become extremely complicated and can be written simply only in terms of expansions of modular functions.

Summand

ADDEND

Summation by Parts

Summation by parts for discrete variables is the equivalent of INTEGRATION BY PARTS for continuous variables

$$\Delta^{-1}[v(x)\Delta(x)] = u(x)v(x) - \Delta^{-1}[Eu(x)\Delta v(x)],$$

or

$$\sum[v(x)\Delta u(x)] = u(x)v(x) - \sum u(x+h)\Delta v(x)],$$

where Δ^{-1} is the indefinite summation operator and the E-operator is defined by

$$Ey(x) = y(x+h),$$

where h is any constant.

See also INTEGRATION BY PARTS

Summatory Function

For a discrete function $f(n)$, the summatory function is defined by

$$F(n) \equiv \sum_{k \in D}^{n} f(k),$$

where D is the DOMAIN of the function.

See also Divisor Function, Mangoldt Function, Mertens Function, Rudin-Shapiro Sequence, Tau Function, Totient Function

Sum-of-Divisors Transform

Möbius Transform

Sum-Product Number

A sum-product number is a number n such that the sum of n's digits times the product of n's digit is n itself, for example

$$135 = (1 + 3 + 5)(1 \cdot 3 \cdot 5).$$

Obviously, such a number must be divisible by its digits as well as the sum of its digits. There are only three sum-product numbers: 1, 135, 144, ... (Sloane's A038369). This can be demonstrated using the following argument due to D. Wilson.

Let n be a d-digit sum-product number, and let s and p be the sum and product of its digits. Because n is a d-digit number, we have

$$10^{d-1} \leq n; \quad s \leq 9d; \quad p \leq 9^d.$$

Now, since n is a sum-product number, we have $n = sp$, giving

$$10^{d-1} \leq n = sp \leq (9d)(9^d).$$

The inequality $10^{d-1} \leq (9d)(9^d)$ is fulfilled only by $d \leq 84$, so a sum-product number has at most 84 digits.

This gives

$$s \leq 9d \leq 756; \quad p \leq n < 10^{85}.$$

Now, since p is a product of digits, p must be of the form $2^a 3^b 5^c 7^d$. However, if 10 divides p, then it also divides n. This means that n ends in 0 so the product of its digit is $p = 0$, giving $n = sp = 0$. Hence we need not consider p divisible by 10, and can assume p is either of the form $2^a 3^b 7^c$ or $3^a 5^b 7^c$. This reduces the search space for sum-product numbers to a tractable size, and allowed Wilson to verify that there are no further sum-product numbers.

Supremum, Supremum Limit

Super Catalan Number

While the Catalan numbers are the number of p-good paths from (n, n) to (0,0) which do not cross the diagonal line, the super Catalan numbers count the number of lattice paths with diagonal steps from (n, n) to (0,0) which do not touch the diagonal line $x = y$.

the super catalan numbers are given by the recurrence relation

$$s(n) = \frac{3(2n-3)s(n-1) - (n-3)s(n-2)}{n}$$

(comtet 1974), with $s(1) = s(2) = 1$. (note that the expression in vardi (1991, p. 198) contains *two* errors.) a closed form expression in terms of Legendre polynomials $P_n(x)$ is

$$S(n) = \frac{3P_{n-1}(3) - P_{n-2}(3)}{4n}$$

(Vardi 1991, p. 199). The first few super Catalan numbers are 1, 1, 3, 11, 45, 197, ... (Sloane's A001003).

Super-3 Number

An integer n such that $h(x)$ contains three consecutive 3s in its decimal representation. The first few super-3 numbers are 261, 462, 471, 481, 558, 753, 1036, ... (Sloane's A014569). A. Anderson has shown that all numbers ending in 471, 4710, or 47100 are super-3 (Pickover 1995).

For a digit d, super-3 numbers can be generalized to super-d numbers n such that $r_4(n)$ contains d ds in its decimal representation. The following table gives the first few super-d numbers for small d.

d	Sloane	Super-d numbers
2	Sloane's A032743	19, 31, 69, 81, 105, 106, 107, 119, 127, ...

Super-d Number

An INTEGER n such that $3n^3$ contains three consecutive 3s in its DECIMAL representation is called a super-3 number. The first few super-3 numbers are 261, 462, 471, 481, 558, 753, 1036, ... (Sloane's A014569). A. Anderson has shown that all numbers ending in 471, 4710, or 47100 are super-3 (Pickover 1995).

In general, a super-d number is a number n such that dn^d contains d ds in its DECIMAL representation. The following table gives the first few super-d numbers for small d.

d	Sloane	super-d numbers
2	A032743	19, 31, 69, 81, 105, 106, 107, 119, ...
3	A014569	261, 462, 471, 481, 558, 753, 1036, ...
4	A032744	1168, 4972, 7423, 7752, 8431, 10267, ...
5	A032745	4602, 5517, 7539, 12955, 14555, 20137, ...
6	A032746	27257, 272570, 302693, 323576, ...
7	A032747	140997, 490996, 1184321, 1259609, ...
8	A032748	185423, 641519, 1551728, 1854230, ...
9	A032749	17546133, 32613656, 93568867, ...

The following table gives the first few palindromic super-d numbers for small d.

d	Sloane	palindromic super-d numbers
2	A032750	131, 181, 333, 454, 919, 969, 1331, ...

Superdiagonal

The superdiagonal of a SQUARE MATRIX is the set of elements directly above the elements comprising the DIAGONAL. For example, in the following matrix, the diagonal elements are denoted d_i and the superdiagonal elements are denoted s_i,

$$\begin{bmatrix} d_1 & s_1 & a_{13} & \cdots & a_{1n} \\ a_{21} & d_2 & s_2 & \ddots & a_{2n} \\ a_{31} & a_{32} & d_3 & \ddots & a_{3n} \\ \vdots & \ddots & \ddots & \ddots & \ddots \\ a_{n1} & a_{n2} & a_{n3} & \cdots & d_n \end{bmatrix}.$$

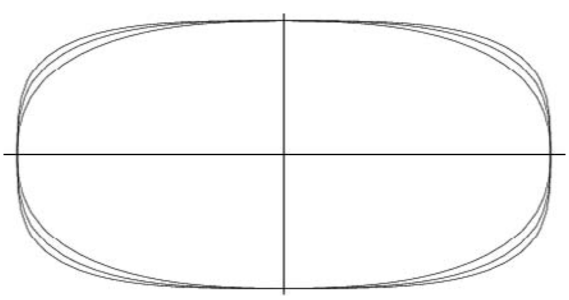
Superegg

A superegg is a solid described by the equation

$$\left|\sqrt{\frac{x^2+y^2}{a^2}}\right|^n + \left|\frac{z}{b}\right|^n = 1.$$



Supereggs will balance on either end for any a, b, and n.

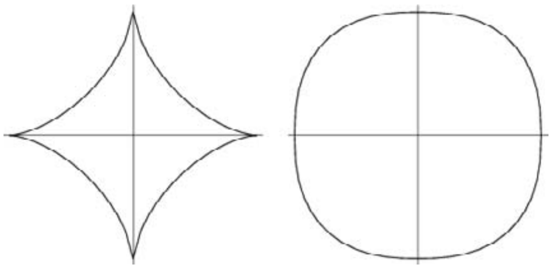
References

Gardner, M. "Piet Hein's Superellipse." Ch. 18 in *Mathematical Carnival: A New Round-Up of Tantalizers and Puzzles from Scientific American.* New York: Vintage, pp. 240–54, 1977.

Superellipse

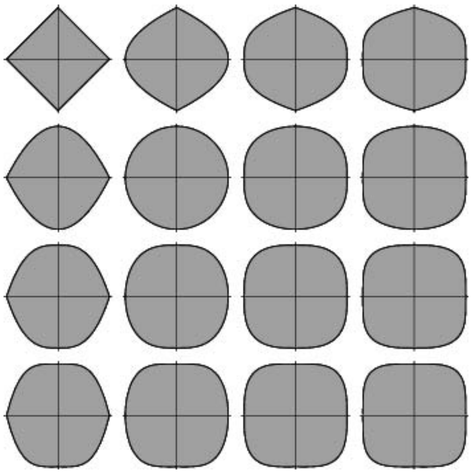


A curve with Cartesian equation

$$\left|\frac{x}{a}\right|^n + \left|\frac{y}{b}\right|^n = 1. \quad (1)$$

where $n > 2$, first discussed in 1818 by Lamé. The curves illustrated above correspond to $a = 1$, $b = 2$, and $n = 2.5$, 3.0, and 3.5. Superellipses with $a = b$ are also known as Lamé curves. The AREA of the superellipse with $a = b = 1$ is given by

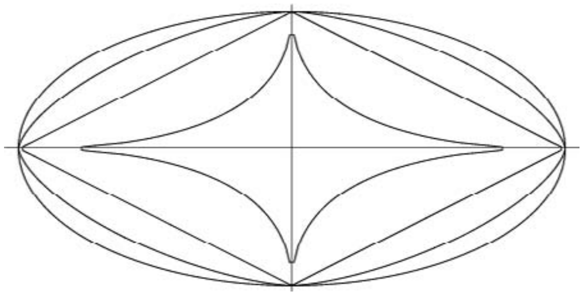
$$A = 4\int_0^1 (1 - x^n)^{1/n}\,dx \quad (2)$$



$$= \frac{2\Gamma\left(\frac{1}{n}\right)\Gamma\left(1+\frac{1}{n}\right)}{\Gamma\left(\frac{2}{n}\right)}. \quad (3)$$

If n is a rational, then the curve is algebraic. However, for irrational n, the curve is transcendental. For EVEN INTEGERS n, the curve becomes closer to a rectangle as n increases. For ODD INTEGER values of n, the curve looks like the EVEN case in the POSITIVE quadrant but goes to infinity in both the second and fourth quadrants (MacTutor Archive). A special case of the superellipse is given by the ASTROID ($n = 2/3$),

$$(ax)^{2/3} + (by)^{2/3} = \left(a^2 - b^2\right)^{2/3} \quad (4)$$



(left figure). Piet Hein called the curve with $n = 5/2$ and $a = b$ "the" superellipse (right figure).

The above plots show the function

$$|x|^p + |y|^q \quad (5)$$

for $p = 1, ..., 4$ and $q = 1, ..., 4$.

A degenerate superellipse is a superellipse with $r \leq 2$. The above curves are for $a = 1$, $b = 2$, and $r = 0.5$, 1.0, 1.5, and 2.0.

Superellipsoid

A generalization of the ELLIPSOID, also called the superquadratic ellipsoid, defined by the equation

$$\left(|x|^{2/e} + |y|^{2/e}\right)^{e/n} + |z|^{2/n} = 1. \tag{1}$$

where e and n are the east-west and north-south exponents, respectively. The superellipsoid can be rendered in *POVRay* ® with the command

```
superellipsoid{ <e,n> }
```

The generalization

$$\left|\frac{x}{a}\right|^n + \left|\frac{y}{b}\right|^n + \left|\frac{z}{c}\right|^n = 1 \tag{2}$$

of the surface considered by Gray (1997) might also be called a superellipsoid. The VOLUME of the solid with $a = b = c = 1$ is

$$V_n = 8\int_0^1 \int_0^{(1-x^n)^{1/n}} (1 - x^n - y^n)^{1/n}\, dy\, dx \tag{3}$$

$$= \frac{8\Gamma\left(1 + \frac{1}{n}\right)}{\Gamma\left(1 + \frac{3}{n}\right)}. \tag{4}$$

As $n \to \infty$, the solid becomes a CUBE, so

$$\lim_{n\to\infty} V_n = 8 \tag{5}$$

as it must. This is a special case of the integral 3.2.2.2

$$\iiint_{\substack{x\geq 0,\ y\geq 0,\ z\geq 0 \\ \left(\frac{x}{a}\right)^p + \left(\frac{y}{b}\right)^q + \left(\frac{z}{c}\right)^r \leq 1}} x^{\alpha-1} y^{\beta-1} z^{\gamma-1}\, dx\, dy\, dz$$

$$= \frac{a^\alpha b^\beta c^\gamma}{pqr} \frac{\Gamma\left(\frac{\alpha}{p}\right)\Gamma\left(\frac{\beta}{q}\right)\Gamma\left(\frac{\gamma}{r}\right)}{\Gamma\left(\frac{\alpha}{p} + \frac{\beta}{q} + \frac{\gamma}{r}\right)} \tag{6}$$

in Prudnikov *et al.* (1986, p. 583).

Superfactorial

The superfactorial of n is defined by Pickover (1995) as

$$n\$ \equiv \underbrace{n!^{n!^{\cdot^{\cdot^{n!}}}}}_{n!}.$$

The first two values are 1 and 4, but subsequently grow so rapidly that 3$ already has a huge number of digits.

Sloane and Plouffe (1995) define the superfactorial by

$$n\$ \equiv \prod_{i=1}^{n} i!,$$

which is equivalent to the integral values of the BARNES' G-FUNCTION. The first few values are 1, 1, 2, 12, 288, 34560, ... (Sloane's A000178). This function has an unexpected connection with BELL NUMBERS.

Supernormal

Trials for which the LEXIS RATIO

$$L \equiv \frac{\sigma}{\sigma_B},$$

satisfies $L > 1$, where σ is the VARIANCE in a set of s LEXIS TRIALS and σ_B is the VARIANCE assuming BERNOULLI TRIALS.

See also BERNOULLI TRIAL, LEXIS TRIALS, SUBNORMAL

Superperfect Number

A number n such that

$$\sigma^2(n) = \sigma(\sigma(n)) = 2n.$$

where $\sigma(n)$ is the DIVISOR FUNCTION is called a superperfect number. EVEN superperfect numbers are just 2^{p-1}, where $M_p = 2^p - 1$ is a MERSENNE PRIME. If any ODD superperfect numbers exist, they are SQUARE NUMBERS and either n or $\sigma(n)$ is DIVISIBLE by at least three distinct PRIMES.

More generally, an m-superperfect number is a number for which $\sigma^m(n) = 2n$, and an (m, k)-perfect number is a number n for which $\sigma^m(n) = 2n$. A number n can tested to see if it is (m, k)-perfect using the following *Mathematica* code.

```
SuperperfectQ[m_,     n_,     k_:2]     :=
Nest[DivisorSigma[1, #] &, n, m] == k n
```

The first few (2,2)-perfect numbers are 2, 4, 16, 64, 4096, 65536, 262144, ... (Sloane's A019279; Cohen and te Riele 1996). For $m \geq 3$, there are no EVEN m-superperfect numbers (Guy 1994, p. 65). There are no $(3, 2)$-superperfect numbers $n < 2 \cdot 10^8$ for $4 \leq m \leq 5$.

Superquadratic Ellipsoid

SUPERELLIPSOID

Superregular Graph

For a VERTEX x of a GRAPH, let Γ_x and Δ_x denote the SUBGRAPHS of $\Gamma - x$ induced by the VERTICES adjacent to and nonadjacent to x, respectively. The empty graph is defined to be superregular, and Γ is said to be superregular if Γ is a REGULAR GRAPH and both Γ_x and Δ_x are superregular for all x.

The superregular graphs are precisely C_5, mK_n $(m, n \geq 1)$, G_n $(n \geq 1)$, and the complements of these graphs, where C_n is a CYCLIC GRAPH, K_n is a COMPLETE GRAPH and mK_n is m disjoint copies of K_n, and G_n is the Cartesian product of K_n with itself (the graph whose VERTEX set consists of n^2 VERTICES arranged in an $n \times n$ square with two VERTICES adjacent IFF they are in the same row or column).

See also COMPLETE GRAPH, CYCLIC GRAPH, REGULAR GRAPH

Superscript

A quantity displayed above the normal line of text (and generally in a smaller point size), as the "i" in x^i, is called a superscript. Superscripts are commonly used to indicate raising to a POWER (x^3 means $x \cdot x \cdot x$ or x CUBED), multiple differentiation ($f^{(3)}(x)$ is an

abbreviation for $f'''(x) = d^3 f/dx^3$), and a host of other operations and notations in mathematics.

See also SUBSCRIPT

Superset

A SET containing all elements of a smaller SET. If B is a SUBSET of A, then A is a superset of B, written $A \supseteq B$. If A is a PROPER SUPERSET of B, this is written $A \supset B$.

See also PROPER SUBSET, PROPER SUPERSET, SUBSET

Superstructure

In NONSTANDARD ANALYSIS, the limitation to first-order analysis can be avoided by using a construction known as a superstructure. Superstructures are constructed in the following manner. Let X be an arbitrary set whose elements are not sets, and call the elements of X "individuals." Define inductively a sequence of sets with $S_0(X) = X$ and, for each natural number k,

$$S_{k+1}(X) = S_k(X) \cup \mathfrak{P}(S_k(X)),$$

and let

$$S(X) = \bigcup_{k=0}^{\infty} S_k(X). \tag{1}$$

Then $S(X)$ is called the superstructure over X. An element of $S(X)$ is an ENTITY of $S(X)$.

Using the definition of ordered pair provided by Kuratowski, namely $(a, b) = \{\{a\}, \{a, b\}\}$, it follows that $(a, b) \in S_2(X)$ for any $a, b \in X$. Therefore, $X \times X \subseteq S_2(X)$, and for any function f from X into X, we have $f \in S_3(X)$. Now assume that the set X is (in one-to-one correspondence with) the set of real numbers $\mathbb{R}$, and then the relation R which describes continuity of a function at a point is a member of $S_6(X)$. Careful consideration shows that, in fact, all the objects studied in classical analysis over $\mathbb{R}$ are entities of this superstructure. Thus, first-order formulas about $S(X)$ are sufficient to study even what is normally done in classical analysis using second-order reasoning.

To do nonstandard analysis on the superstructure $S(X)$, one forms an ULTRAPOWER of the relational structure $(S(X), \in)$. LOS' THEOREM yields the TRANSFER PRINCIPLE of nonstandard analysis.

See also LOS' THEOREM, NONSTANDARD ANALYSIS, ULTRAPOWER

Supremum

Portions of this entry contributed by JEROME R. BREITENBACH

The supremum is the least upper bound of a set S, defined as a quantity M such that no member of the SET exceeds M, but if ϵ is any POSITIVE quantity, however small, there is a member that exceeds $M - \epsilon$ (Jeffreys and Jeffreys 1988). When it exists (which is not required by this definition, e.g., sup $\mathbb{R}$ does not exist), is it denoted $\sup_S$ or $\sup_{x \in S}$.

More formally, the supremum $\sup S$ for S a (nonempty) SUBSET of the extended reals $\bar{\mathbb{R}} = \mathbb{R} \cup \{\pm\infty\}$ is the smallest value $y \in \bar{\mathbb{R}}$ such that for all $x \in S$ we have $x \leq y$. Using this definition, $\sup S$ *always* exists and, in particular, $\sup \mathbb{R} = \infty$.

Whenever a supremum exists, its value is unique. On the REAL LINE, the supremum of a set is the same as the supremum of its CLOSURE.

Supremum Limit

Given a sequence of real numbers a_n, the supremum limit, also called the UPPER LIMIT, but more often simply called the supremum limit and pronounced 'lim-soup' and written lim sup, is the limit of

$$A_n = \sup_{k>n} a_k$$

as $n \to \infty$, where $\sup_S$ denotes the SUPREMUM. Note that, by definition, A_n is nonincreasing and so either has a limit or tends to $-\infty$. For example, suppose $a_n = (-1)^n/n$, then for n odd, $A_n = 1/(n+1)$, and for n even, $A_n = 1/n$. Another example is $a_n = \sin n$, in which case A_n is a constant sequence $A_n = 1$.

When $\limsup a_n = \liminf a_n$, the sequence converges to the real number

$$\lim a_n = \limsup a_n = \liminf a_n.$$

Otherwise, the sequence does not converge.

Surd

An archaic term for an IRRATIONAL NUMBER.

See also IRRATIONAL NUMBER, QUADRATIC SURD

Surface

The word "surface" is an important term in mathematics and is used in many ways. The most common and straightforward use of the word is to denote a 2-D SUBMANIFOLD of 3-D EUCLIDEAN SPACE. Surfaces can range from the very complicated (e.g., FRACTALS such as the MANDELBROT SET) to the very simple (such as the PLANE). More generally, the word "surface" can be used to denote an $(n-1)$-D SUBMANIFOLD of an n-D MANIFOLD, or in general, any CODIMENSION-1 subobject in an object (like a BANACH SPACE or an infinite-dimensional MANIFOLD).

Even simple surfaces can display surprisingly counterintuitive properties. For example, the SURFACE OF REVOLUTION of $y = 1/x$ around the X-AXIS for $x \geq 1$ (called GABRIEL'S HORN) has FINITE VOLUME but INFINITE SURFACE AREA.

Surface Area

Surface area is the AREA of a given surface. Roughly speaking, it is the "amount" of a surface (i.e., it is proportional to the amount of paint needed to cover it), and has units of distance squared. It is commonly denoted S for a surface in 3-D, or A for a region of the plane (in which case it is simply called "the" AREA).

If the surface is PARAMETERIZED using u and v, then

$$S = \int_S |\mathbf{T}_u \times \mathbf{T}_v| \, du \, dv, \tag{1}$$

where $\mathbf{T}_u$ and $\mathbf{T}_v$ are tangent vectors and $\mathbf{a} \times \mathbf{b}$ is the CROSS PRODUCT. If $z = f(x, y)$ is defined over a region R, then

$$S = \int\int_R \sqrt{\left(\frac{\partial z}{\partial x}\right)^n + \left(\frac{\partial z}{\partial y}\right)^2 + 1} \, dA, \tag{2}$$

where the integral is taken over the entire surface (Kaplan 1992, 3rd ed. pp. 245–48). Writing $x = x(u, v)$, $y = y(u, v)$, and $z = z(u, v)$ then gives the symmetrical form

$$S = \int\int_{R'} \sqrt{EG - F^2} \, du \, dv. \tag{3}$$

where R' is the transformation of R, and

$$E = \left(\frac{\partial x}{\partial u}\right)^2 + \left(\frac{\partial y}{\partial u}\right)^2 + \left(\frac{\partial z}{\partial u}\right)^2 \qquad (4)$$

$$F = \frac{\partial x}{\partial u}\frac{\partial x}{\partial v} + \frac{\partial y}{\partial u}\frac{\partial y}{\partial v} + \frac{\partial z}{\partial u}\frac{\partial z}{\partial v} \qquad (5)$$

$$G = \left(\frac{\partial x}{\partial v}\right)^2 + \left(\frac{\partial y}{\partial v}\right)^2 + \left(\frac{\partial z}{\partial v}\right)^2 \qquad (6)$$

are coefficients of the first FUNDAMENTAL FORM (Kaplan 1992, 3rd ed. pp. 245–46).

The following tables gives *lateral* surface areas S for some common SURFACES. Here, r denotes the RADIUS, h the height, e the ELLIPTICITY of a SPHEROID, p the base PERIMETER, s the SLANT HEIGHT, a the tube radius of a torus, and c the radius from the rotation axis of the torus to the center of the tube (Beyer 1987). Note that many of these surfaces are SURFACES OF REVOLUTION.

SURFACE	S
CONE	$\pi r\sqrt{r^2+h^2}$
CONICAL FRUSTUM	$\pi(R_1+R_2)\sqrt{(R_1-R_2)^2+h^2}$
CUBE	$6a^2$
CYLINDER	$2\pi rh$
OBLATE SPHEROID	$2\pi a^2+\frac{\pi e^2}{e}\ln\left(\frac{1+e}{1-e}\right)$
PROLATE SPHEROID	$2\pi a^2+\frac{2\pi ae}{e}\sin^{-1}e$
PYRAMID	$\frac{1}{2}ps$
PYRAMIDAL FRUSTUM	$\frac{1}{2}ps$
SPHERE	$4\pi r^2$
SPHERICAL LUNE	$2r^2\theta$
TORUS	$4\pi^2 ac$
ZONE	$2\pi rh$

Even simple surfaces can display surprisingly counterintuitive properties. For instance, the surface of revolution of $y = 1/x$ around the x-AXIS for $x \geq 1$ is called GABRIEL'S HORN, and has FINITE VOLUME but INFINITE surface area.

Surface Harmonic

Any LINEAR COMBINATION of real SPHERICAL HARMONICS

$$A_l P_l(\cos\theta) + \sum_{m=1}^{l}[A_l^m \cos(m\phi) + B_l^m \sin(m\phi)]P_l^m(\cos\theta)$$

for l fixed whose sum is not premultiplied by a factor r^l (Whittaker and Watson 1990, p. 392).

Surface Integral

For a SCALAR FUNCTION f over a surface parameterized by u and v, the surface integral is given by

$$\Phi = \int_S f\,da = \int_S f(u, v)|\mathbf{T}_u \times \mathbf{T}_v|\,du\,dv. \qquad (1)$$

where $\mathbf{T}_u$ and $\mathbf{T}_v$ are tangent vectors and $\mathbf{a} \times \mathbf{b}$ is the CROSS PRODUCT.

For a VECTOR FUNCTION over a surface, the surface integral is given by

$$\Phi = \int_S \mathbf{F}\cdot d\mathbf{a} = \int_S (\mathbf{F}\cdot\hat{\mathbf{n}})\,da \qquad (2)$$

$$= \int_S f_x\,dy\,dz + f_y\,dz\,dx + f_z\,dx\,dy. \qquad (3)$$

where $\mathbf{a}\cdot\mathbf{b}$ is a DOT PRODUCT and $\hat{\mathbf{n}}$ is a unit NORMAL VECTOR. If $z = f(x, y)$, then $d\mathbf{a}$ is given explicitly by

$$d\mathbf{a} = \pm\left(-\frac{\partial z}{\partial x}\hat{\mathbf{x}} - \frac{\partial z}{\partial y}\hat{\mathbf{y}} + \hat{\mathbf{z}}\right)dx\,dy. \qquad (4)$$

If the surface is SURFACE PARAMETERIZED using u and v, then

$$\Phi = \int_S \mathbf{F}\cdot(\mathbf{T}_u \times \mathbf{T}_v)\,du\,dv. \qquad (5)$$

Surface of Revolution

A surface of revolution is a SURFACE generated by rotating a 2-D CURVE about an axis. The resulting surface therefore always has azimuthal symmetry. Examples of surfaces of revolution include the APPLE, CONE (excluding the base), CONICAL FRUSTUM (excluding the ends), CYLINDER (excluding the ends), DARWIN-DE SITTER SPHEROID, GABRIEL'S HORN, HYPERBOLOID, LEMON, OBLATE SPHEROID, PARABOLOID, PROLATE SPHEROID, PSEUDOSPHERE, SPHERE, SPHEROID, and TORUS (and its generalization, the TOROID).

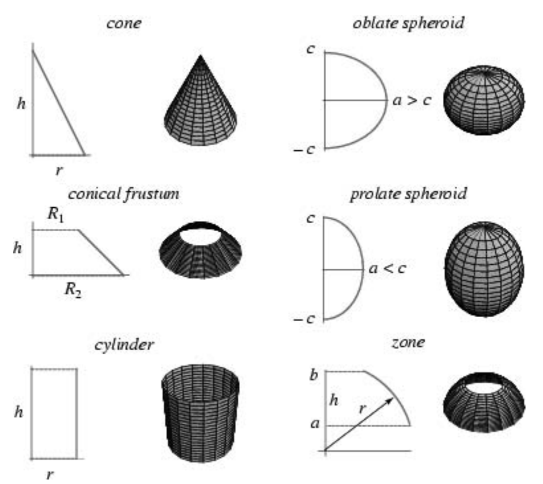
The area element of the SURFACE OF REVOLUTION obtained by rotating the curve $y = f(x)$ from $x = a$ to $x = b$ about the X-AXIS is

$$dS = 2\pi y\, ds = 2\pi y\sqrt{1 + y'^2}\, dx. \tag{1}$$

so the surface area is

$$S = 2\pi \int_a^b f(x)\sqrt{1 + [f'(x)]^2}\, dx. \tag{2}$$

(Anton 1999, p. 380).



If we are interested instead in finding the area of the SURFACE OF REVOLUTION obtained by rotating the curve $x = g(y)$ around the Y-AXIS from $y = a$ to $y = b$ (as opposed to rotating about the X-AXIS), the area element is given by

$$dS = 2\pi x\, ds = 2\pi x\sqrt{1 + x'^2}\, dy. \tag{3}$$

so the surface area is

$$S = 2\pi \int_a^b g(y)\sqrt{1 + [g'(y)]^2}\, dy \tag{4}$$

(Kaplan 1992, 3rd ed. p. 251; Anton 1999, p. 380).

The following table gives the *lateral* surface areas S for some common surfaces of revolution where r denotes the RADIUS (of a cone, cylinder, sphere, or zone), R_1 and R_2 the inner and outer radii of a frustum, h the height, e the ELLIPTICITY of a SPHEROID, and a and c the equatorial and polar radii (for a spheroid) or the radius of a circular cross-section and rotational radius (for a torus).

surface	S
CONE	$\pi r\sqrt{r^2 + h^2}$
CONICAL FRUSTUM	$\pi(R_1 + R_2)\sqrt{(R_1 - R_2)^2 + h^2}$
CYLINDER	$2\pi rh$
OBLATE SPHEROID	$2\pi a^2 + \frac{\pi e^2}{e}\ln\left(\frac{1+e}{1-e}\right)$
PROLATE SPHEROID	$2\pi a^2 + \frac{2\pi ae}{e}\sin^{-1} e$
SPHERE	$4\pi r^2$
TORUS	$4\pi^2 ac$
ZONE	$2\pi rh$

The standard parameterization of a surface of revolution is given by

$$x(u, v) = \phi(v)\cos u \tag{5}$$

$$y(u, v) = \phi(v)\sin u \tag{6}$$

$$z(u, v) = \psi(v). \tag{7}$$

For a curve so parameterized, the first FUNDAMENTAL FORM has

$$E = \psi^2 \tag{8}$$

$$F = 0 \tag{9}$$

$$G = \phi'^2 + \psi'^2. \tag{10}$$

Wherever ϕ and $\phi'^2 + \psi'^2$ are nonzero, then the surface is regular and the second FUNDAMENTAL FORM has

$$e = -\frac{|\phi|\psi'}{\sqrt{\phi'^2 + \psi'^2}} \tag{11}$$

$$f = 0 \tag{12}$$

$$g = \frac{\operatorname{sgn}(\phi)(\phi''\psi' - \phi'\psi'')}{\sqrt{\phi'^2 + \psi'^2}}. \tag{13}$$

Furthermore, the unit NORMAL VECTOR is

$$\hat{\mathbf{N}}(u, v) = \frac{\operatorname{sgn}(\phi)}{\sqrt{\phi'^2 + \psi'^2}} \begin{bmatrix} \phi' \cos u \\ \psi' \sin u \\ \phi' \end{bmatrix}. \tag{14}$$

and the PRINCIPAL CURVATURES are

$$\kappa_1 = \frac{g}{G} = \frac{\operatorname{sgn}(\phi)(\phi''\psi' - \phi'\psi'')}{(\phi'^2 + \psi'^2)^{3/2}} \tag{15}$$

$$\kappa_2 = \frac{e}{E} = -\frac{\psi'}{|\phi|\sqrt{\phi'^2 + \psi'^2}}. \tag{16}$$

The GAUSSIAN and MEAN CURVATURES are

$$K = \frac{-\psi'^2\phi'' + \phi'\psi'\psi''}{\phi(\phi'^2 + \psi'^2)^2} \tag{17}$$

$$H = \frac{\phi(\phi''\psi' - \phi'\psi'') - \psi'(\phi'^2 + \psi'^2)}{2|\phi|(\phi'^2 + \psi'^2)^{3/2}} \tag{18}$$

(Gray 1997).

PAPPUS'S CENTROID THEOREM gives the VOLUME of a solid of rotation as the cross-sectional AREA times the distance traveled by the centroid as it is rotated.

CALCULUS OF VARIATIONS can be used to find the curve from a point (x_1, y_1) to a point (x_2, y_2) which, when revolved around the X-AXIS, yields a surface of smallest SURFACE AREA A (i.e., the MINIMAL SURFACE). This is equivalent to finding the MINIMAL SURFACE passing through two circular wire frames. The AREA element is

$$dA = 2\pi y\, ds = 2\pi y \sqrt{1 + y'^2}\, dx. \tag{19}$$

so the SURFACE AREA is

$$A = 2\pi \int y\sqrt{1 + y'^2}\, dx. \tag{20}$$

and the quantity we are minimizing is

$$f = y\sqrt{1 + y'^2}. \tag{21}$$

This equation has $f_x = 0$, so we can use the BELTRAMI IDENTITY

$$f - y_x \frac{\partial f}{\partial y_x} = a \tag{22}$$

to obtain

$$y\sqrt{1 + y'^2} - y' \frac{yy'}{\sqrt{1 + y'^2}} = a \tag{23}$$

$$y(1 + y'^2) - yy'^2 = a\sqrt{1 + y'^2} \tag{24}$$

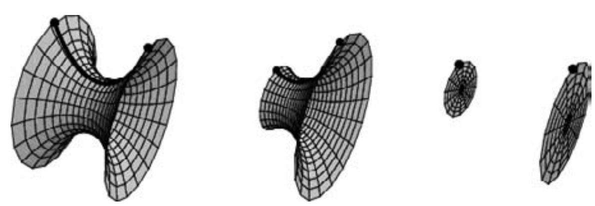
$$y = a\sqrt{1 + y'^2} \tag{25}$$

$$\frac{y}{\sqrt{1 + y'^2}} = a \tag{26}$$

$$\frac{y^2}{a} - 1 = y'^2 \tag{27}$$

$$\frac{dx}{dy} = \frac{1}{y'} = \frac{a}{\sqrt{y^2 - a^2}} \tag{28}$$

$$x = a \int \frac{dy}{\sqrt{y^2 - a^2}} = a \cosh^{-1}\left(\frac{y}{a}\right) + b \tag{29}$$



$$y = a \cosh\left(\frac{x - b}{a}\right). \tag{30}$$

which is called a CATENARY, and the surface generated by rotating it is called a CATENOID. The two constants a and b are determined from the two implicit equations

$$y_1 = a \cosh\left(\frac{x_1 - b}{a}\right) \tag{31}$$

$$y_2 = a \cosh\left(\frac{x_2 - b}{a}\right). \tag{32}$$

which cannot be solved analytically.

The general case is somewhat more complicated than this solution suggests. To see this, consider the MINIMAL SURFACE between two rings of equal RADIUS y_0. Without loss of generality, take the origin at the midpoint of the two rings. Then the two endpoints are located at $(-x_0, y_0)$ and (x_0, y_0), and

$$y_0 = a \cosh\left(\frac{-x_0 - b}{a}\right) = a \cosh\left(\frac{x_0 - b}{a}\right). \tag{33}$$

But $\cosh(-x) = \cosh(x)$, so

$$\cosh\left(\frac{-x_0 - b}{a}\right) = \cosh\left(\frac{-x_0 + b}{a}\right). \tag{34}$$

Inverting each side

$$-x_0 - b = -x_0 + b. \tag{35}$$

so $b = 0$ (as it must by symmetry, since we have chosen the origin between the two rings), and the equation of the MINIMAL SURFACE reduces to

$$y = a \cosh\left(\frac{x}{a}\right), \tag{36}$$

At the endpoints

$$y_0 = a \cosh\left(\frac{x_0}{a}\right). \tag{37}$$

but for certain values of x_0 and y_0, this equation has no solutions. The physical interpretation of this fact is that the surface breaks and forms circular disks in each ring to minimize AREA. CALCULUS OF VARIATIONS cannot be used to find such discontinuous solutions (known in this case as GOLDSCHMIDT SOLUTIONS). The minimal surfaces for several choices of endpoints are shown above. The first two cases are CATENOIDS, while the third case is a GOLDSCHMIDT SOLUTION.

To find the maximum value of x_0/y_0 at which CATENARY solutions can be obtained, let $p \equiv 1/a$. Then (35) gives

$$y_0 p = \cosh(p x_0). \tag{38}$$

Now, denote the maximum value of x_0 as x_0^*. Then it will be true that $dx_0/dp = 0$. Take d/dp of (38),

$$y_0 = \sinh(p x_0)\left(x_0 + p\frac{dx_0}{dp}\right). \tag{39}$$

Now set $dx_0/dp = 0$

$$y_0 = x_0 \sinh(p x_0{}^*). \tag{40}$$

From (38),

$$p y_0{}^* = \cosh(p x_0{}^*). \tag{41}$$

Take (41) ÷ (40),

$$p x_0{}^* = \coth(p x_0{}^*). \tag{42}$$

Defining $u \equiv p x_0{}^*$,

$$u = \coth u. \tag{43}$$

This has solution $u = 1.1996789403\ldots$. From (40), $y_0 p = \cosh u$. Divide this by (43) to obtain $y_0/x_0 = \sinh u$, so the maximum possible value of x_0/y_0 is

$$\frac{x_0}{y_0} = \operatorname{csch} u = 0.6627434193\ldots. \tag{44}$$

Therefore, only Goldschmidt ring solutions exist for $x_0/y_0 > 0.6627\ldots$.

The SURFACE AREA of the minimal CATENOID surface is given by

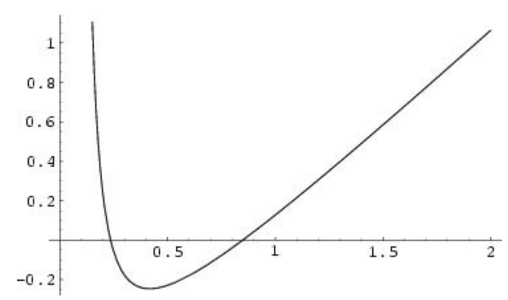
$$A = 2(2\pi)\int_0^{x_0} y\sqrt{1+y'^2}\,dx, \tag{45}$$

but since

$$y = \sqrt{1+y'^2}\,a \tag{46}$$

$$= a \cosh\left(\frac{x}{a}\right). \tag{47}$$

$$A = \frac{4\pi}{a}\int_0^{x_0} y^2\,dx = 4\pi a\int_0^{x_0}\cosh^2\left(\frac{x}{a}\right)dx$$



$$= 4\pi a\int_0^{x_0}\tfrac{1}{2}\left[\cosh\left(\frac{2x}{a}\right)+1\right]dx$$

$$= 2\pi a\left[\int_0^{x_0}\cosh\left(\frac{2x}{a}\right)dx + \int_0^{x_0}dx\right]$$

$$= 2\pi a\left[\frac{a}{2}\sinh\left(\frac{2x}{a}\right)+x\right]_0^{x_0}$$

$$= \pi a^2\left[\sinh\left(\frac{2x}{a}\right)+\frac{2x}{a}\right]_0^{x_0}$$

$$= \pi a^2\left[\sinh\left(\frac{2x_0}{a}\right)+\frac{2x_0}{a}\right]. \tag{48}$$

Some caution is needed in solving (37) for a. If we take $x_0 = 1/2$ and $y_0 = 1$ then (37) becomes

$$1 = a \cosh\left(\frac{1}{2a}\right). \tag{49}$$

which has *two* solutions: $a_1 = 0.2350\ldots$ ("deep"), and $a_2 = 0.8483\ldots$ However, upon plugging these into (48) with $x_0 = 1/2$, we find $A_1 = 6.8456\ldots$ and $A_2 = 5.9917\ldots$. So A_1 is *not,* in fact, a local minimum, and A_2 is the only *true* minimal solution.

The SURFACE AREA of the CATENOID solution equals that of the GOLDSCHMIDT SOLUTION when (48) equals the AREA of two disks,

$$\pi a^2\left[\sinh\left(\frac{2x_0}{a}\right)+\frac{2x_0}{a}\right] = 2\pi y_0^2 \tag{50}$$

$$a^2\left[2\sinh\left(\frac{x_0}{a}\right)\cosh\left(\frac{x_0}{a}\right)+\frac{2x_0}{a}\right] - 2y_0^2 = 0 \tag{51}$$

$$a^2\left[\cosh\left(\frac{x_0}{a}\right)\sqrt{\cosh^2\left(\frac{x_0}{a}\right)-1}+\frac{x_0}{a}\right] - y_0^2 = 0. \tag{52}$$

Plugging in

$$\frac{y_0}{a} = \cosh\left(\frac{x_0}{a}\right). \tag{53}$$

$$\frac{y_0}{a}\sqrt{\left(\frac{y_0}{a}\right)^2 - 1} + \cosh^{-1}\left(\frac{y_0}{a}\right) - \left(\frac{y_0}{a}\right)^2 = 0. \tag{54}$$

Defining

$$u \equiv \frac{y_0}{a} \tag{55}$$

gives

$$u\sqrt{u^2-1} + \cosh^{-1} u - u^2 = 0. \tag{56}$$

This has a solution $u = 1.2113614259$. The value of x_0/y_0 for which

$$A_{\text{catenary}} = A_{2 \text{ disks}} \tag{57}$$

is therefore

$$\frac{x_0}{y_0} = \frac{\frac{x_0}{a}}{\frac{y_0}{a}} = \frac{\cosh^{-1}\left(\frac{y_0}{a}\right)}{\frac{y_0}{a}} = \frac{\cosh^{-1} u}{u}$$
$$= 0.5276973967. \tag{58}$$

For $x_0/y_0 \in \{0.52770,\ 0.6627\}$, the CATENARY solution has larger AREA than the two disks, so it exists only as a RELATIVE MINIMUM.

There also exist solutions with a disk (of radius r) between the rings supported by two CATENOIDS of revolution. The AREA is larger than that for a simple CATENOID, but it is a RELATIVE MINIMUM. The equation of the POSITIVE half of this curve is

$$y = c_1 \cosh\left(\frac{x}{c_1} + c_3\right). \tag{59}$$

At $(0,\ r)$,

$$r = c_1 \cosh(c_3). \tag{60}$$

At $(x_0,\ y_0)$,

$$y_0 = c_1 \cosh\left(\frac{x_0}{c_1} + c_3\right). \tag{61}$$

The AREA of the two CATENOIDS is

$$A_{\text{catenoids}} = 2(2\pi)\int_0^{x_0} y\sqrt{1+y'^2}\,dx = \frac{4\pi}{c_1}\int_0^{x_0} y^2\,dx$$
$$= 4\pi c_1 \int_0^{x_0} \cosh^2\left(\frac{x}{c_1} + c_3\right) dx. \tag{62}$$

Now let $u \equiv x/c_1 + c_3$, so $du = dx/c_1$

$$A = 4\pi c_1^2 \int_{c_3}^{x_0/x_1 + c_3} \cosh^2 u\, du$$
$$= 4\pi c_1^2\, \tfrac{1}{2} \int_{c_3}^{x_0/x_1 + c_3} [\cosh(2u) + 1]\, du$$
$$= 2\pi c_1^2 \left[\tfrac{1}{2}\sinh(2u) + u\right]_{c_3}^{x_0/x_1 + c_3}$$
$$= 2\pi c_1^2 \left\{\tfrac{1}{2}\sinh\left[2\left(\frac{x_0}{c_1} + c_3\right)\right] - \tfrac{1}{2}\sinh(2c_3) + \frac{x_0}{c_1}\right\}$$
$$= \pi c_1^2 \left\{\sinh\left[2\left(\frac{x_0}{c_1} + c_3\right)\right] - \sinh(2c_3) + \frac{2x_0}{c_1}\right\}. \tag{63}$$

The AREA of the central DISK is

$$A_{\text{disk}} = \pi r^2 = \pi c_1^2 \cosh^2 c_3, \tag{64}$$

so the total AREA is

$$A = \pi c_1^2 \times \left\{\sinh\left[2\left(\frac{x_0}{c_1} + c_3\right)\right] + \left[\cosh^2 c_3 - \sinh(2c_3)\right] + \frac{2x_0}{c_1}\right\}. \tag{65}$$

By PLATEAU'S LAWS, the CATENOIDS meet at an ANGLE of 120°, so

$$\tan 30° = \left[\frac{dy}{dx}\right]_{x=0} = \left[\sinh\left(\frac{x}{c_1} + c_3\right)\right]_{x=0}$$
$$= \sinh c_3 = \frac{1}{\sqrt{3}} \tag{66}$$

and

$$c_3 = \sinh^{-1}\left(\frac{1}{\sqrt{3}}\right). \tag{67}$$

This means that

$$\cosh^2 c_3 - \sinh(2c_3)$$
$$= \left[1 + \sinh^2 c_3\right] - 2\sinh c_3\sqrt{1+\sinh^2 c_3}$$
$$= \left(1 + \tfrac{1}{3}\right) - 2\left(\frac{1}{\sqrt{3}}\right)\sqrt{1+\tfrac{1}{3}}$$
$$= \frac{4}{3} - \frac{2}{\sqrt{3}}\,\frac{2}{\sqrt{3}} = 0. \tag{68}$$

so

$$A = \pi c_1^2 \left\{\sinh\left[2\left(\frac{x_0}{c_1} + c_3\right)\right] + \frac{2x_0}{c_1}\right\}. \tag{69}$$

Now examine x_0/y_0,

$$\frac{x_0}{y_0} = \frac{\frac{x_0}{c_1}}{\frac{y_0}{c_1}} = \frac{\frac{x_0}{c_1}}{\cosh\left(\frac{x_0}{c_1} + c_3\right)} u \operatorname{sech}(u + c_3). \quad (70)$$

where $u \equiv x_0/c_1$. Finding the maximum ratio of x_0/y_0 gives

$$\frac{d}{du}\left(\frac{x_0}{y_0}\right) = \operatorname{sech}(u + c_3) - u \tanh(u + c_3) \operatorname{sech}(u + c_3)$$

$$= 0 \quad (71)$$

$$u \tanh(u + c_3) = 1. \quad (72)$$

with $c_3 = \sinh^{-1}(1/\sqrt{3})$ as given above. The solution is $u = 1.0799632187$, so the maximum value of x_0/y_0 for two CATENOIDS with a central disk is $y_0 = 0.4078241702$.

If we are interested instead in finding the curve from a point (x_1, y_1) to a point (x_2, y_2) which, when revolved around the Y-AXIS (as opposed to the X-AXIS), yields a surface of smallest SURFACE AREA A, we proceed as above. Note that the solution is physically equivalent to that for rotation about the X-AXIS, but takes on a different mathematical form. The AREA element is

$$dA = 2\pi x\, ds = 2\pi x \sqrt{1 + y'^2}\, dx \quad (73)$$

$$A = 2\pi \int x\sqrt{1 + y'^2}\, dx. \quad (74)$$

and the quantity we are minimizing is

$$f = x\sqrt{1 + y'^2}. \quad (75)$$

Taking the derivatives gives

$$\frac{\partial f}{\partial y} = 0 \quad (76)$$

$$\frac{d}{dx}\frac{\partial f}{\partial y'} = \frac{d}{dx}\left(\frac{xy'}{\sqrt{1 + y'^2}}\right). \quad (77)$$

so the EULER-LAGRANGE DIFFERENTIAL EQUATION becomes

$$\frac{\partial f}{\partial y} - \frac{d}{dx}\frac{\partial f}{\partial y'} = \frac{d}{dx}\left(\frac{xy'}{\sqrt{1 + y'^2}}\right) = 0. \quad (78)$$

$$\frac{xy'}{\sqrt{1 + y'^2}} = a \quad (79)$$

$$x^2 y'^2 = a^2(1 + y'^2) \quad (80)$$

$$y'^2(x^2 - a^2) = a^2 \quad (81)$$

$$\frac{dy}{dx} = \frac{a}{\sqrt{x^2 - a^2}} \quad (82)$$

$$y = a \int \frac{dx}{\sqrt{x^2 - a^2}} + b = a \cosh^{-1}\left(\frac{x}{a}\right) + b. \quad (83)$$

Solving for x then gives

$$x = a \cosh\left(\frac{y - b}{a}\right). \quad (84)$$

which is the equation for a CATENARY. The SURFACE AREA of the CATENOID product by rotation is

$$A = 2\pi \int x\sqrt{1 + y'^2}\, dx = 2\pi \int x\sqrt{1 + \frac{a^2}{x^2 - a^2}}\, dx$$

$$= 2\pi \int \frac{x}{\sqrt{x^2 - a^2}} \sqrt{(x^2 - a^2) + a^2}\, dx$$

$$= 2\pi \int \frac{x^2\, dx}{\sqrt{x^2 - a^2}}$$

$$= \left[\frac{x}{2}\sqrt{x^2 - a^2} + \frac{a^2}{2}\ln\left(x + \sqrt{x^2 - a^2}\right)\right]_{x_1}^{x_2}$$

$$= \frac{1}{2}\left[x_2\sqrt{x_2^2 - a^2} - x_1\sqrt{x_1^2 - a^2} + a^2 \ln\left(\frac{x_2 + \sqrt{x_2^2 - a^2}}{x_1 + \sqrt{x_1^2 - a^2}}\right)\right]. \quad (85)$$

Isenberg (1992, p. 80) discusses finding the MINIMAL SURFACE passing through two rings with axes offset from each other.

Surface of Section

A surface (or "space"rpar; of section is a way of presenting a trajectory in n-D PHASE SPACE in an $(n-1)$-D SPACE. By picking one phase element constant and plotting the values of the other elements

each time the selected element has the desired value, an intersection surface is obtained. If the equations of motion can be formulated as a MAP in which an explicit FORMULA gives the values of the other elements at successive passages through the selected element value, the time required to compute the surface of section is greatly reduced.

Surface Parameterization

A surface in 3-SPACE can be parameterized by two variables (or coordinates) u and v such that

$$x = x(u,\ v) \tag{1}$$

$$y = y(u,\ v) \tag{2}$$

$$z = z(u,\ v). \tag{3}$$

If a surface is parameterized as above, then the tangent VECTORS

$$\mathbf{T}_u = \frac{\partial x}{\partial u}\ \hat{\mathbf{x}} + \frac{\partial y}{\partial u}\ \hat{\mathbf{y}} + \frac{\partial z}{\partial u}\ \hat{\mathbf{z}} \tag{4}$$

$$\mathbf{T}_v = \frac{\partial x}{\partial v}\ \hat{\mathbf{x}} + \frac{\partial y}{\partial v}\ \hat{\mathbf{y}} + \frac{\partial z}{\partial v}\ \hat{\mathbf{z}} \tag{5}$$

are useful in computing the SURFACE AREA and SURFACE INTEGRAL.

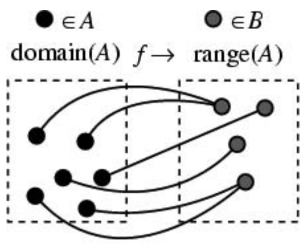
Surgery



In the process of attaching a k-HANDLE to a MANIFOLD M, the BOUNDARY of M is modified by a process called $(k-1)$-surgery. Surgery consists of the removal of a TUBULAR NEIGHBORHOOD of a $(k-1)$-SPHERE $\mathbb{S}^{(k-1)}$ from the BOUNDARIES of M and the $\dim(M)-1$ standard SPHERE, and the gluing together of these two scarred-up objects along their common BOUNDARIES.

Surreal Number

The most natural collection of numbers which includes both the REAL NUMBERS and the infinite ORDINAL NUMBERS of Georg Cantor. They were invented by John H. Conway in 1969. Every REAL NUMBER is surrounded by surreals, which are closer to it than any REAL NUMBER. Knuth (1974) describes the surreal numbers in a work of fiction.

The surreal numbers are written using the NOTATION $\{a|b\}$, where $\{|\}=0$, $\{0|\}=1$ is the simplest number greater than 0, $\{1|\}=2$ is the simplest number greater than 1, etc. Similarly, $\{|0\}=-1$ is the simplest number less than 1, etc. However, 2 can also be represented by $\{1|3\}$, $\{3/2|4\}$, $\{1|\omega\}$, etc.

Survivorship Curve

Plotting l_x from a LIFE EXPECTANCY table on a logarithmic scale versus x gives a curve known as a survivorship curve. There are three general classes of survivorship curves, illustrated above.

1. Type I curves are typical of populations in which most mortality occurs among the elderly (e.g., humans in developed countries).
2. Type II curves occur when mortality is not dependent on age (e.g., many species of large birds and fish). For an infinite type II population, $e_0 = e_1 = \ldots$, but this cannot hold for a finite population.
3. Type III curves occur when juvenile mortality is extremely high (e.g., plant and animal species producing many offspring of which few survive). In type III populations, it is often true that $e_{i+1} > e_i$ for small i. In other words, life expectancy increases for individuals who survive their risky juvenile period.

Suzanne Set

The nth Suzanne set S_n is defined as the set of COMPOSITE NUMBERS x for which $n|S(x)$ and $n|S_p(x)$, where

$$x = a_0 + a_1(10^1) + \ldots + a_d(10^d) = p_1 p_2 \cdots p_n.$$

and

$$S(x) = \sum_{j=0}^{d} a_j$$

$$S_p(x) = \sum_{i=1}^{m} S(p_i).$$

Every Suzanne set has an infinite number of elements. The Suzanne set S_n is a superset of the MONICA SET M_n.

Swallowtail Catastrophe

A CATASTROPHE which can occur for three control factors and one behavior axis. The swallowtail catastrophe is the universal unfolding of singularity $f(x)=x^5$ with codimension 3, i.e., in three unfolding parameters, and is of the form $F(x, u, v, w)=x^5+ux^3+vx^2+wx$. The equations

$$x=uv^2+3v^4$$

$$y=-2uv-4v^3$$

$$z=u$$

display such a catastrophe (von Seggern 1993, Nordstrand). The above surface uses $u \in [-2, 2]$ and $v \in [-0.8, 0.8]$.

Swinnerton-Dyer Conjecture

In the early 1960s, B. Birch and H. P. F. Swinnerton-Dyer conjectured that if a given ELLIPTIC CURVE has an infinite number of solutions, then the associated L-series has value 0 at a certain fixed point. In 1976, Coates and Wiles showed that elliptic curves with COMPLEX multiplication having an infinite number of solutions have L-series which are zero at the relevant fixed point (COATES-WILES THEOREM), but they were unable to prove the converse. V. Kolyvagin extended this result to modular curves.

Sylow p-Subgroup

If p^k is the highest power of a prime p dividing the order of a finite group G, then a subgroup of G of order p^k is called a Sylow p-subgroup of G.

See also Abhyankar's Conjecture, Subgroup, Sylow Theorems

Sylow Theorems

Let p be a prime number, G a finite group, and $|G|$ the order of G.

1. If p divides $|G|$, then G has a Sylow p-subgroup.
2. In a finite group, all the Sylow p-subgroups are conjugate for some fixed p.
3. The number of Sylow p-subgroups for a fixed p is congruent to 1 (mod p).

See also Conjugate Subgroup, Sylow p-Subgroup

Sylvester Cyclotomic Number

Given a Lucas sequence with parameters P and Q, discriminant $D \neq 0$, and roots α and β, the Sylvester cyclotomic numbers are

$$Q_n = \prod_r (\alpha - \zeta^r \beta).$$

where

$$\zeta \equiv \cos\left(\frac{2\pi}{n}\right) + i \sin\left(\frac{2\pi}{n}\right)$$

is a primitive root of unity and the product is over all exponents r relatively prime to n such that $r \in [1,\ n)$.

Sylvester Matrix

For polynomials of degree m and n, the Sylvester matrix is an $(m+n) \times (m+n)$ matrix whose determinant is the resultant of the two polynomials.

See also Determinant, Resultant

Sylvester's Determinant Identity

Given a MATRIX A, let |A| denote its determinant. Then

$$|A||A_{rs,\,pq}| = |A_{r,\,p}||A_{s,\,q}| - |A_{r,\,q}||A_{s,\,p}|, \quad (1)$$

where $A_{u,\,w}$ is the SUBMATRIX of A formed by the intersection of the subset w of columns and u of rows. Bareiss (1968) writes the identity as

$$|A|\left[a_{kk}^{(k-1)}\right]^{n-k-1} = \begin{vmatrix} a_{k+1,\,k-1}^{(k)} & \cdots & a_{k+1,\,n}^{(k)} \\ \vdots & \ddots & \vdots \\ a_{n,\,k+1}^{(k)} & \cdots & a_{n,\,n}^{(k)} \end{vmatrix}. \quad (2)$$

where

$$a_{ij}^{(k)} = \begin{vmatrix} a_{11} & a_{12} & \cdots & a_{1k} & a_{ij} \\ a_{21} & a_{22} & \cdots & a_{2k} & a_{2j} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ a_{k1} & a_{k2} & \cdots & a_{kk} & a_{kj} \\ a_{i1} & a_{i2} & \cdots & a_{ik} & a_{ij} \end{vmatrix} \quad (3)$$

for $k < i,\ j \le n$.

Sylvester's Four-Point Problem

Sylvester's four-point problem asks for the probability $q(R)$ that four points chosen at random in a planar region R have a CONVEX HULL which is a QUADRILATERAL (Sylvester 1865). Depending on the method chosen to pick points from the infinite plane, a number of different solutions are possible, prompting Sylvester to conclude "This problem does not admit of a determinate solution" (Sylvester 1865; Pfiefer 1989).

For points selected from an open, convex subset of the PLANE having finite AREA, the probability if given by

$$P(R) = 1 - \frac{4\bar{A}_R}{A(R)}.$$

where $\bar{A}_R$ is the expected area of a triangle over region R and $A(R)$ is the area of region R. Note that $\bar{A}_R$ is simply the value computed for an appropriate region, e.g., DISK TRIANGLE PICKING, TRIANGLE TRIANGLE PICKING, SQUARE TRIANGLE PICKING, etc. $P(R)$ can range between

$$\tfrac{2}{3} \le q(R) \le 1 - \frac{35}{12\pi^2} \quad (1)$$

($0.66666 \le q(R) \le 0.70448$) depending on the shape of the region, as first proved by Blaschke (Blaschke 1923, Peyerimhoff 1997). The following table gives the probabilities for various simple plane regions (Kendall and Moran 1963; Pfiefer 1989; Croft *et al.* 1991, pp. 54–5; Peyerimhoff 1997).

R	$P(R)$	approx.
TRIANGLE	$\frac{2}{3}$	0.66667
SQUARE	$\frac{25}{36}$	0.69444
HEXAGON	$\frac{683}{972}$	0.70267
ELLIPSE, CIRCLE	$1-\frac{35}{12\pi^2}$	0.70448

Sylvester's problem can be generalized to ask for the probability that the CONVEX HULL of $n+2$ randomly chosen points in the UNIT BALL $\mathbb{B}^n$ has $n+1$ vertices. The solution is given by

$$P_n = \frac{(n+2)\binom{n+1}{\frac{1}{2}(n+1)}^{n+1}}{2^n \binom{(n+1)^2}{\frac{1}{2}(n+1)^2}} \quad (2)$$

(Kingman 1969, Groemer 1973, Peyerimhoff 1997), which is the maximum possible for any bounded convex domain $K \in \mathbb{R}^n$. The first few values are

$$P_1 = 1$$

$$P_2 = \frac{35}{12\pi^2}$$

$$P_3 = \frac{9}{143}$$

$$P_4 = \frac{676039}{648000\pi^4}$$

$$P_5 = \frac{20000}{12964479}$$

(Sloane's A051050 and A051051).

Another generalization asks the probability that n randomly chosen points in a fixed bounded convex domain $K \subset \mathbb{R}^2$ are the vertices of a convex n-gon. The solution is

$$P_n = \frac{2^n(3n-3)!}{[(n-1)!]^3(2n)!} \quad (3)$$

for a triangular domain, which has first few values 1, 1, 1, 2/3, 11/36, 91/900, 17/675, ... (Sloane's A004677 and A004824), and

$$P_n = \left[\frac{1}{n!}\binom{2n-2}{n-1}\right]^2 \quad (4)$$

for a parallelogram domain, which has first few values 1, 1, 1, 25/36, 49/144, 121/3600, ... (Sloane's A004936 and A005017; Valtr 1996, Peyerimhoff 1997).

Sylvester's four-point problem has an unexpected connection with the RECTILINEAR CROSSING NUMBER of graphs (Finch).

Sylvester's Inertia Law

The numbers of EIGENVALUES that are POSITIVE, NEGATIVE, or 0 do not change under a congruence transformation. Gradshteyn and Ryzhik (2000) state it as follows: when a QUADRATIC FORM Q in n variables is reduced by a nonsingular linear transformation to the form

$$Q = y_1^2 + y_2^2 + \ldots + y_p^2 - p_{p+1}^2 - y_{p_2}^2 - \ldots - y_r^2.$$

the number p of POSITIVE SQUARES appearing in the reduction is an invariant of the QUADRATIC FORM Q and does not depend on the method of reduction.

See also EIGENVALUE, QUADRATIC FORM

Sylvester's Sequence

The sequence defined by $e_0 = 2$ and the RECURRENCE RELATION

$$e_n = 1 + \prod_{i=0}^{n-1} e_i = e_{n-1}^2 - e_{n-1} + 1. \quad (1)$$

This sequence arises in Euclid's proof that there are an INFINITE number of PRIMES. The proof proceeds by

constructing a sequence of PRIMES using the RECURRENCE RELATION

$$e_{n+1} = e_0 e_1 \cdots e_n + 1 \tag{2}$$

(Vardi 1991). Amazingly, there is a constant

$$E \approx 1.264084735306 \tag{3}$$

such that

$$e_n = \left\lfloor E^{2n+1} + \tfrac{1}{2} \right\rfloor \tag{4}$$

(Vardi 1991, Graham *et al.* 1994). The first few numbers in Sylvester's sequence are 2, 3, 7, 43, 1807, 3263443, 10650056950807, ... (Sloane's A000058). The e_n satisfy

$$\sum_{n=0}^{\infty} \frac{1}{e_n} = 1. \tag{5}$$

In addition, if $0 < x < 1$ is an IRRATIONAL NUMBER, then the nth term of an infinite sum of unit fractions used to represent x as computed using the GREEDY ALGORITHM must be smaller than $1/e_n$.

The n of the first few PRIME e_n are 0, 1, 2, 3, 5, ..., corresponding to 2, 3, 7, 43, 3263443, ... (Sloane's A014546). Vardi (1991) gives a lists of factors less than 5×10^7 of e_n for $n \leq 200$ and shows that e_n is COMPOSITE for $6 \leq n \leq 17$. Furthermore, all numbers less than 2.5×10^{15} in Sylvester's sequence are SQUAREFREE, and no SQUAREFUL numbers in this sequence are known (Vardi 1991).

See also EUCLID'S THEOREMS, GREEDY ALGORITHM, SQUAREFREE, SQUAREFUL

Sylvester's Signature

Diagonalize a form over the RATIONALS to

$$\operatorname{diag}[p^a \cdot A, p^b \cdot B, \ldots].$$

where all the entries are INTEGERS and A, B, ...are RELATIVELY PRIME to p. Then Sylvester's signature is the sum of the -1-parts of the entries.

See also p-SIGNATURE

Sylvester's Triangle Problem

The resultant of the vectors represented by the three RADII from the center of a TRIANGLE'S CIRCUMCIRCLE to its VERTICES is the segment extending from the CIRCUMCENTER to the ORTHOCENTER.

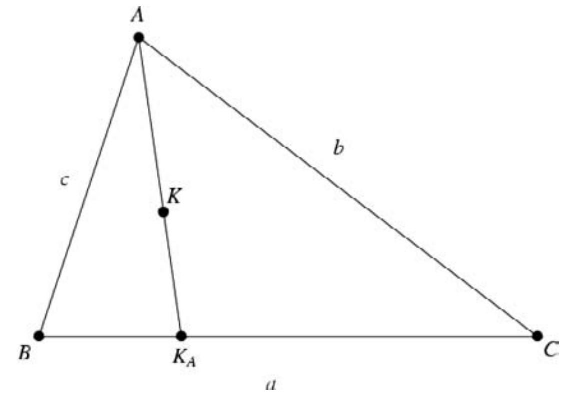
Symmedian Point

The point of concurrence K of the SYMMEDIANS, sometimes also called the LEMOINE POINT (in England and France) or the GREBE POINT (in Germany). Equivalently, the symmedian point is the ISOGONAL CONJUGATE of the CENTROID G. In other words, let G be the CENTROID of a TRIANGLE ΔABC, AM_A, BM_B, and CM_C the medians of ΔABC, AL_A, BL_B, and CL_C the ANGLE BISECTORS of ANGLES A, B, C, and AK_A, BK_B, and CK_C the reflections of AM_A, BM_B, and CM_C about AL_A, BL_B, and CL_C. Then K is the point of concurrence of the lines AK_A, BK_B, and CK_C. According to Honsberger (1995, p. 53), the symmedian point is "one of the crown jewels of modern geometry."

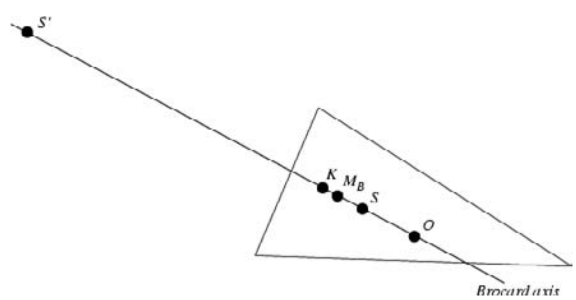


The TRILINEAR COORDINATES of the symmedian point is

$$a : b : c \tag{1}$$

(Honsberger 1995, p. 75), or

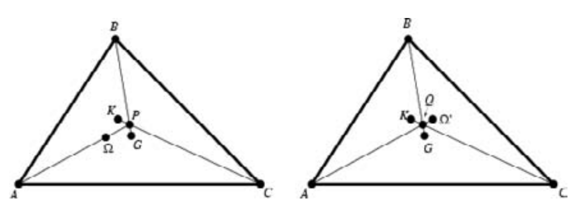
$$\sin A : \sin B : \sin C. \tag{2}$$



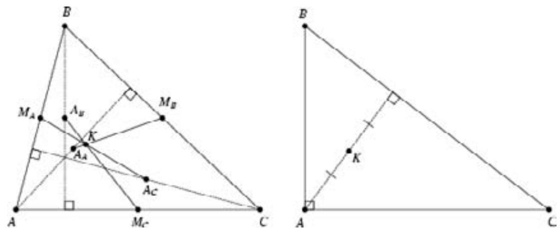
In AREAL COORDINATES (actual TRILINEAR COORDINATES), the symmedian point is the point for which $\alpha^2 + \beta^2 + \gamma^2$ is a minimum (Honsberger 1995, pp. 75–6). A center X is the CENTROID of its own PEDAL TRIANGLE IFF it is the symmedian point. The symmedian point is the perspectivity center of a TRIANGLE and its TANGENTIAL TRIANGLE.

In the above diagram with K the symmedian point,

$$\frac{AK}{KK_A} = \frac{b^2 + c^2}{a^2} \tag{3}$$



(Honsberger 1995, p. 76).



The symmedian point lies on the BROCARD AXIS, and its distances from K to the sides of the TRIANGLE are

$$KK_i = \tfrac{1}{2} a_i \tan \omega, \tag{4}$$

where ω is the BROCARD ANGLE.

One BROCARD LINE, MEDIAN, and SYMMEDIAN (out of the three of each) are CONCURRENT, with $A\Omega$, CK, and BG meeting at a point, where Ω is the first BROCARD POINT and G is the CENTROID. Similarly, $A\Omega'$, BG, and CK, where Ω' is the second BROCARD POINT, meet at a point which is the ISOGONAL CONJUGATE of the first (Johnson 1929, pp. 268–69).

The line joining the MIDPOINT of any side to the midpoint of the ALTITUDE on that side passes through K (left figure). In particular, the symmedian point of a RIGHT TRIANGLE is the MIDPOINT of the ALTITUDE to the HYPOTENUSE (right figure; Honsberger 1995, p. 59). The symmedian point K is the STEINER POINT of the first BROCARD TRIANGLE.

$\xrightarrow{6}100011\xrightarrow{3}10101\xrightarrow{3}1110\xrightarrow{0}111\xrightarrow{4}1011\ldots$

Given a triangle ΔABC, construct the triangle $\Delta A'B'C'$ obtained as the intersection of the lines extended from each vertex though the symmedian point K of ΔABC with the CIRCUMCIRCLE of ΔABC. Then the symmedian point of $\Delta A'B'C'$ is again K (Honsberger 1995, p. 77).

The tangents to the CIRCUMCIRCLE of a triangle at two of its vertices meet on the SYMMEDIAN from the third vertex (Honsberger 1995, pp. 60–1). The GERGONNE POINT of a triangle is the symmedian point of its CONTACT TRIANGLE (Honsberger 1995, pp. 62–3). The symmedian point of a triangle is the CENTROID of its PEDAL TRIANGLE. And finally, the lengths of the sides of the PEDAL TRIANGLE of the symmedian point are proportional to the lengths of the MEDIANS of the original triangle (Honsberger 1995, p. 77)

Symmetric

A mathematical object is said to be symmetric if it is invariant ("looks the same") under a symmetry transformation.

A function, matrix, etc., is symmetric if it remains unchanged in SIGN when indices are reversed. For example, $A_{ij} \equiv a_i + a_j$ is symmetric since $A_{ij} = A_{ji}$.

See also ANTISYMMETRIC, SYMMETRIC FUNCTION, SYMMETRY

Symmetric Bilinear Form

A symmetric bilinear form on a VECTOR SPACE V is a BILINEAR FUNCTION

$$Q : V \times V \to \mathbb{R} \tag{1}$$

which satisfies $Q(v, w) = Q(w, v)$.

For example, if A is a $n \times n$ SYMMETRIC MATRIX, then

$$Q(v, w) = v^{\mathrm{T}}\mathsf{A}w = \langle v, \mathsf{A}w\rangle \tag{2}$$

is a symmetric bilinear form. Consider

$$A = \begin{bmatrix} 1 & 2 \\ 2 & -3 \end{bmatrix}, \tag{3}$$

then

$$Q((a_1, a_2), (b_1, b_2)) = a_1b_1 + 2a_1b_2 + 2a_2b_1 - 3a_2b_2. \tag{4}$$

Here is a *Mathematica* function which takes a matrix to a bilinear form.

```
MatrixToForm[a_List?MatrixQ][v_, w_] := v.a.w
```

For example,

```
q = MatrixToForm[{{0, 1}, {1, -2}}];
  q[{1, 0}, {1, 7}]
```

yields 7.

A QUADRATIC FORM may also be labeled Q, because quadratic forms are in a one-to-one correspondence with symmetric bilinear forms. Note that $Q(a) = Q(a, a)$ is a QUADRATIC FORM. If $Q(a)$ is a quadratic form then it defines a symmetric bilinear form by

$$Q(a, b) = \tfrac{1}{2}[Q(a+b) - Q(a) - Q(b)]. \tag{5}$$

The kernel, or radical, of a symmetric bilinear form is the set of vectors

$$\ker Q = \{v : Q(v, w) = 0 \textit{ for all } w \in V\}. \tag{6}$$

A quadratic form is called nondegenerate if its kernel is zero. That is, if for all $v \in V$, there is a $w \in V$ with $Q(v, w) \neq 0$. The rank of Q is the rank of the matrix $(a_{ij}) = Q(e_i, e_j)$.

The form Q is diagonalized if there is a basis v_i, called an orthogonal basis, such that $(b_{ij}) = Q(v_i, v_j)$ is a DIAGONAL MATRIX. Alternatively, there is a matrix C such that

$$Q(Cv, Cw) = (C_v)^T A(Cw) = v^T(C^T AC)w \tag{7}$$

is a DIAGONAL QUADRATIC FORM. The jth column of the matrix C is the vector v_j.

A nondegenerate symmetric bilinear form can be DIAGONALIZED, using GRAM-SCHMIDT ORTHONORMALIZATION to find the v_i, so that the diagonal matrix $C^T AC$ has entries either 1 or -1. If there are p 1s and q -1s, then Q is said to have SIGNATURE (p, q), or if the dimension is understood then just signature p. Real nondegenerate symmetric bilinear forms are classified by their signature, in the sense that given two vector spaces with forms of signature (p, q), there is an isomorphism of the vector spaces which takes one form to the other.

A symmetric bilinear form with $Q(v, v) > 0$, for all nonzero v, is called POSITIVE DEFINITE. For example, the usual inner product is positive definite. A positive definite form has signature $(n, 0)$. A negative definite form is the negative of a positive form and has signature $(0, n)$. If the form is neither positive definite nor negative definite, then there must exist vectors $w \neq 0$ such that $Q(w, w) = 0$, called isotropic vectors.

A general symmetric bilinear form Q can be diagonalized with diagonal entries 1, -1, or 0, because the form Q is always nondegenerate on the QUOTIENT VECTOR SPACE $V/\ker Q$. If V is a COMPLEX VECTOR SPACE, then a symmetric bilinear form can be diagonalized to have entries 1 or 0. For other FIELDS, there are more SYMMETRIC BILINEAR FORMS than in the real or complex case. For instance, if the FIELD has CHARACTERISTIC 2, then it is not possible to divide by 2 since $2 = 0$. Hence there is no correspondence between quadratic forms and symmetric bilinear forms in characteristic 2.

See also DIAGONAL QUADRATIC FORM, FIELD, INDEX (MATRIX), INNER PRODUCT, QUADRATIC FORM, SIGNATURE, SYMMETRIC BILINEAR FORM (GENERAL FIELDS), VECTOR SPACE

References

Serre, J. P. *A Course in Arithmetic.* New York: Springer-Verlag, pp. 27–5, 1973.

Symmetric Bilinear Form (General Fields)

The symmetric bilinear forms on a VECTOR SPACE, whose FIELD k is not real, have been classified for some FIELDS. There are also theorems about symmetric bilinear forms on free Abelian groups, for example $\mathbb{Z}^n$.

A SYMMETRIC BILINEAR FORM Q corresponds to a matrix A by giving a basis e_i and setting $a_{ij} = Q(e_i, e_j)$. Two symmetric bilinear forms are considered equivalent if a change of basis takes one to the other. Hence, $A \sim CAC^T$, where C is any invertible matrix. Therefore, the rank of the symmetric bilinear form is an invariant.

Also, det A can change by $(\det C)^2 \det A$. The coset of $\det A$ in k^*/k^{*2} is a WELL DEFINED invariant of Q, called the discriminant. For real forms, it is either 1 or -1. For $\mathbb{Q}$, the discriminant can be any RATIONAL NUMBER a/b where a and b are SQUAREFREE. A symmetric bilinear form on a FINITE FIELD is determined by its rank and its discriminant.

A symmetric bilinear form on the P-ADIC NUMBERS $\mathbb{Q}_p$ is characterized by its rank, discriminant, and another invariant $e(Q)$. Given a basis e_i, orthogonal for Q, define $a_i = Q(e_1, e_2)$, then

$$e(Q) = \prod_{i<j} (a_i, a_j)$$

where (a_i, a_j) is the HILBERT SYMBOL.

Two symmetric bilinear forms are equivalent on the RATIONALS iff they are equivalent in every $\mathbb{Q}_p$ as well as the reals (also called $\mathbb{Q}_\infty$.) The data in $\mathbb{Q}_p$ can be thought of as "local" information, which can be patched together to yield "global" information in $\mathbb{Q}$. So rational forms have a countable number of distinct invariants, three for every PRIME NUMBER, and two for the reals.

Symmetric Block Design

A symmetric design is a BLOCK DESIGN (v, k, λ, r, b) with the same number of blocks as points, so $b = v$ (or, equivalently, $r = k$). An example of a symmetric block design is a PROJECTIVE PLANE.

See also BLOCK DESIGN, PROJECTIVE PLANE

Symmetric Design

SYMMETRIC BLOCK DESIGN

Symmetric Difference

The set of elements belonging to one *but not both* of two given sets. It is therefore the UNION of the COMPLEMENT of A with respect to B and B with respect to A, and corresponds to the XOR operation in Boolean logic. The symmetric difference can be implemented in *Mathematica* as

```
SymmetricDifference[a_, b_] :=
Union[Complement[a, b], Complement[b, a]]
```

The symmetric difference of sets A and B is variously written as $A \ominus B$, $A \nabla B$, or $A+B$. The latter two notations are deprecated since these symbols have common meanings in other areas of mathematics.

For example, for $A=\{1, 2, 3, 4\}$ and $B=\{1, 4, 5\}$, $A \ominus B=\{2, 3, 5\}$, since 2, 3, and 5 are each in one, but not both, sets.

See also COMPLEMENT SET, DIFFERENCE, SET DIFFERENCE, UNION, XOR

Symmetric Function

A symmetric function on n variables x_1, ..., x_n is a function that is unchanged by any PERMUTATION of its variables. In most contexts, the term "symmetric function" refers to a polynomial on n variables with this feature (more properly called a "SYMMETRIC POLYNOMIAL"). Another type of symmetric functions is symmetric rational functions, which are the RATIONAL FUNCTIONS that are unchanged by PERMUTATION of variables.

The SYMMETRIC POLYNOMIALS (respectively, symmetric rational functions) can be expressed as polynomials (respectively, rational functions) in the SYMMETRIC POLYNOMIALS. This is called the FUNDAMENTAL THEOREM OF SYMMETRIC FUNCTIONS.

A function $f(x)$ is sometimes said to be symmetric about the Y-AXIS if $f(-x)=f(x)$. Examples of such functions include $|x|$ (the ABSOLUTE VALUE) and x^2 (the PARABOLA).

See also FUNDAMENTAL THEOREM OF SYMMETRIC FUNCTIONS, RATIONAL FUNCTION, SYMMETRIC POLYNOMIAL

Symmetric Group

The symmetric group S_n of degree n is the GROUP of all PERMUTATIONS on n symbols. S_n is therefore of ORDER $n!$ and contains as SUBGROUPS every GROUP of ORDER n. The number of CONJUGACY CLASSES of S_n is given by the PARTITION FUNCTION P.

For example, let $\{abc\}$ denote the permutation on three elements which takes the ath element to position 1, the bth element to position 2, and the cth element to position 3. Then the following table gives the MULTIPLICATION TABLE for S_n, containing $3!=6$ elements with $\{123\}$ the IDENTITY ELEMENT. The multiplication table can be generated using the *Mathematica* function

```
SymmetricGroup[n_Integer?Positive] := Module[
   {p = Permutations[Range[n]], i, j},
   Table[p[[i]][[p[[j]]]], {i, n!}, {j, n!}]
  ]
```

NETTO'S CONJECTURE states that the probability that two elements P_1 and P_2 of a symmetric group generate the entire group tends to 3/4 as $n \to \infty$. This was proven by Dixon (1969). The probability that two elements generate S_n for $n = 1, 2, ...$ are 1, 3/4, 1/2, 3/8, 19/40, 53/120, 103/168, ... (Sloane's A040173 and A040174). Finding a general formula for terms in the sequence is a famous UNSOLVED PROBLEM in GROUP THEORY.

Symmetric Matrix

A symmetric matrix is a SQUARE MATRIX which satisfies $\mathsf{A}^{\mathrm{T}} = \mathsf{A}$ where A^{T} denotes the TRANSPOSE, so $a_{ij} = a_{ji}$. This also implies

$$\mathsf{A}^{-1}\mathsf{A}^{\mathrm{T}} = \mathsf{I}, \tag{1}$$

where I is the IDENTITY MATRIX. For example,

$$\mathsf{A} = \begin{bmatrix} 4 & 1 \\ 1 & -2 \end{bmatrix} \tag{2}$$

is a symmetric matrix. HERMITIAN MATRICES are a useful generalization of symmetric matrices for COMPLEX MATRICES

A matrix m can be tested to see if it is symmetric using the *Mathematica* function

```
SymmetricQ[m_List?MatrixQ] := (m === Transpose[m])
```

Written explicitly, the elements of a symmetric matrix A have the form

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix} \tag{3}$$

The symmetric part of any MATRIX may be obtained from

$$\mathsf{A}_s = \tfrac{1}{2}(\mathsf{A} + \mathsf{A}^{\mathrm{T}}). \tag{4}$$

A MATRIX A is symmetric if it can be expressed in the form

$$\mathsf{A} = \mathsf{QDQ}^{\mathrm{T}}, \tag{5}$$

where Q is an ORTHOGONAL MATRIX and D is a DIAGONAL MATRIX. This is equivalent to the MATRIX EQUATION

$$\mathsf{AQ} = \mathsf{QD}, \tag{6}$$

which is equivalent to

$$\mathsf{A}\mathbf{Q}_n = \lambda_n \mathbf{Q}_n \tag{7}$$

for all n, where $\lambda_n = D_{nn}$. Therefore, the diagonal elements of D are the EIGENVALUES of A, and the columns of Q are the corresponding EIGENVECTORS.

The numbers of symmetric matrices of order n on s symbols are s, s^3, s^6, s^{10}, ..., $s^{k(k-1)/2}$. Therefore, for (0,1)-MATRICES, the numbers of distinct symmetric matrices of orders $n = 1, 2, ...$ are 2, 8, 64, 1024, ... (Sloane's A006125).

Symmetric Points

Two points z and $z^S \in \mathbb{C}$ are symmetric with respect to a CIRCLE or straight LINE L if all CIRCLES and straight LINES passing through z and z^S are orthogonal to L. MÖBIUS TRANSFORMATIONS preserve symmetry. Let a straight line be given by a point z_0 and a unit VECTOR $e^{i\theta}$, then

$$z^S = e^{2i\theta}\overline{z - z_0} + z_{0,}$$

where $\bar{z}$ is the COMPLEX CONJUGATE. Let a CIRCLE be given by center z_0 and RADIUS r, then

$$z^S = z_0 + \frac{r^2}{\overline{z - z_0}}.$$

See also MÖBIUS TRANSFORMATION

Symmetric Polynomial

A symmetric polynomial on n variables x_1, ..., x_n is a function that is unchanged by any PERMUTATION of its variables. Symmetric polynomials are always HOMOGENEOUS POLYNOMIALS. The n elementary symmetric functions Π_n (sometimes denoted σ_n) on n variables $\{x_1, \ldots, x_n\}$ are defined by

$$\Pi_1 = \sum_{1 \le i \le n} x_i \tag{1}$$

$$\Pi_2 = \sum_{1 \le i < j \le n} x_i x_j \tag{2}$$

$$\Pi_3 = \sum_{1 \le i < j < k \le n} x_i x_j x_k \tag{3}$$

$$\Pi_4 = \sum_{1 \le i < j < k < l \le n} x_i x_j x_k x_l \tag{4}$$

$$\vdots$$

$$\Pi_n = \sum_{1 \le i \le n} x_i. \tag{5}$$

The kth symmetric polynomial is defined as `SymmetricPolynomial[{x1, ..., xn}, k]` in the *Mathematica* add-on package `Algebra`SymmetricPolyno-`

`mials`` (which can be loaded with the command `<<Algebra``). `SymmetricReduction[`*f*, {*x1*, ..., *xn*}] in the *Mathematica* add-on package `Algebra``-`SymmetricPolynomials`` (which can be loaded with the command `<<Algebra``) gives a pair of polynomials $\{p, q\}$ in $x_1, ..., x_n$ where p is the symmetric part and q is the remainder.

Alternatively, $\Pi_j(x_1, \ldots, x_n)$ can be defined as the coefficient of x^{n-j} in the GENERATING FUNCTION

$$\prod_{1 \le i \le n} (x + x_i). \tag{6}$$

For example, on four variables $x_1, ..., x_4$, the elementary symmetric functions are

$$\Pi_1 = x_1 + x_2 + x_3 + x_4 \tag{7}$$

$$\Pi_2 = x_1x_2 + x_1x_3 + x_1x_4 + x_2x_3 + x_2x_4 + x_3x_4 \tag{8}$$

$$\Pi_3 = x_1x_2x_3 + x_1x_2x_4 + x_1x_3x_4 + x_2x_3x_4 \tag{9}$$

$$\Pi_4 = x_1x_2x_3x_4. \tag{10}$$

Define $s_k(h_1, \ldots, h_n)$ as the coefficients of the GENERATING FUNCTION

$$\ln(1 + x_1t + x_2t^2 + x_3t^3 + \ldots) = \sum_{k=1}^{\infty} \frac{s_1}{k} t^k$$
$$= h_1t + \tfrac{1}{2}(-h_1^2 + 2h_2)t^2 + \tfrac{1}{3}(h_1^3 - 3h_1h_2 + 3h_3)t^3 + \ldots \tag{11}$$

so the first few values are

$$s_1 = h_1 \tag{12}$$

$$s_2 = -h_1^2 + 2h_2 \tag{13}$$

$$s_3 = h_1^3 - 3h_1h_2 + 3h_3 \tag{14}$$

$$s_4 = -h_1^4 + 4h_1^2h_2 - 2h_2^2 - 4h_2h_3 + 4h_4. \tag{15}$$

In general, s_n can be computed from the DETERMINANT

$$s_n = (-1)^{n-1} \begin{vmatrix} h_1 & 1 & 0 & 0 & \cdots & 0 \\ 2h_2 & h_1 & 1 & 0 & \ddots & 0 \\ 3h_3 & h_2 & h_1 & 1 & \ddots & 0 \\ 4h_4 & h_3 & h_2 & h_1 & \ddots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & 1 \\ nh_n & h_{n-1} & h_{n-2} & h_{n-3} & \cdots & h_1 \end{vmatrix} \tag{16}$$

(Littlewood 1958, Cadogan 1971). Then the elementary symmetric functions satisfy the relationship

$$\sum_{k=1}^{n} x_k^p = (-1)^{p-1} s_p(\Pi_1, \ldots, \Pi_n). \tag{17}$$

In particular,

$$\sum_{k=1}^{n} x_k = \Pi_1 \tag{18}$$

$$\sum_{k=1}^{n} x_k^2 = \Pi_1^2 - 2\Pi_2 \tag{19}$$

$$\sum_{k=1}^{n} x_k^3 = \Pi_1^3 - \Pi_1\Pi_2 + 3\Pi_3 \tag{20}$$

$$\sum_{k=1}^{n} x_k^4 = \Pi_1^4 - 4\Pi_1^2\Pi_2 + 2\Pi_2^2 + 4\Pi_1\Pi_3 - 4\Pi_4 \tag{21}$$

(Schroeppel 1972), as can be verified by plugging in and multiplying through.

Symmetric Quadratic Form

See also QUADRATIC FORM

Symmetric Relation

A RELATION R on a SET S is symmetric provided that for every x and y in S we have xRy IFF yRx.

See also RELATION

Symmetric Tensor

A second-RANK symmetric TENSOR is defined as a TENSOR A for which

$$A^{mn} = A^{nm}. \tag{1}$$

Any TENSOR can be written as a sum of symmetric and ANTISYMMETRIC parts

$$A^{mn} = \tfrac{1}{2}(A^{mn} + A^{nm}) + \tfrac{1}{2}(A^{mn} - A^{nm})$$
$$= \tfrac{1}{2}(B_S^{mn} + B_A^{mn}). \tag{2}$$

The symmetric part of a TENSOR is denoted using parentheses as

$$T_{(a,\, b)} \equiv \tfrac{1}{2}(T_{ab} + T_{ba}) \tag{3}$$

$$T_{(a_1,\, a_2,\, \ldots,\, a_n)} \equiv \frac{1}{n!} \sum_{\text{permutations}} T_{a_1a_2\cdots a_n}. \tag{4}$$

Symbols for the symmetric and antisymmetric parts of tensors can be combined, for example

$$T^{(ab)c}{}_{[de]} = \tfrac{1}{4}(T^{abc}{}_{de} + T^{bac}{}_{de} - T^{abc}{}_{ed} - T^{bac}{}_{ed}). \qquad (5)$$

(Wald 1984, p. 26).

The product of a symmetric and an ANTISYMMETRIC TENSOR is 0. This can be seen as follows. Let $a^{\alpha\beta}$ be ANTISYMMETRIC, so

$$a^{11} = a^{22} = 0 \qquad (6)$$

$$a^{21} = -a^{12}. \qquad (7)$$

Let $b_{\alpha\beta}$ be symmetric, so

$$b_{12} = b_{21}. \qquad (8)$$

Then

$$\begin{aligned} a^{\alpha\beta} b_{\alpha\beta} &= a^{11}b_{11} + a^{12}b_{12} + a^{21}b_{21} + a^{22}b_{22} \\ &= 0 + a^{12}b_{12} - a^{12}b_{12} + 0 = 0. \end{aligned} \qquad (9)$$

A symmetric second-RANK TENSOR A_{mn} has SCALAR invariants

$$s_1 = A_{11} + A_{22} + A_{22} \qquad (10)$$

$$s_2 = A_{22}A_{33} + A_{33}A_{11} + A_{11}A_{22} - A_{23}^2 - A_{31}^2 - A_{12}^2. \qquad (11)$$

Symmetry

An intrinsic property of a mathematical object which causes it to remain invariant under certain classes of transformations (such as ROTATION, REFLECTION, INVERSION, or more abstract operations). The mathematical study of symmetry is systematized and formalized in the extremely powerful and beautiful area of mathematics called GROUP THEORY.

Symmetry can be present in the form of coefficients of equations as well as in the physical arrangement of objects. By classifying the symmetry of polynomial equations using the machinery of GROUP THEORY, for example, it is possible to prove the unsolvability of the general QUINTIC EQUATION.

In physics, the extremely powerful NOETHER'S SYMMETRY THEOREM states that each symmetry of a system leads to a physically conserved quantity. Symmetry under TRANSLATION corresponds to momentum conservation, symmetry under ROTATION to angular momentum conservation, symmetry in time to energy conservation, etc.

See also CRYSTALLOGRAPHY RESTRICTION, GROUP THEORY, NOETHER'S SYMMETRY THEOREM

Symmetry Group

GROUP

Symmetry Operation

Symmetry operations include the IMPROPER ROTATION, INVERSION OPERATION, MIRROR PLANE, and

ROTATION. Together, these operations create 32 crystal classes corresponding to the 32 POINT GROUPS.

The INVERSION OPERATION takes

$$(x, y, z) \rightarrow (-x, -y, -z)$$

and is denoted i. When used in conjunction with a ROTATION, it becomes an IMPROPER ROTATION. An IMPROPER ROTATION by $360°/n$ is denoted $\bar{n}$ (or S_n). For periodic crystals, the CRYSTALLOGRAPHY RESTRICTION allows only the IMPROPER ROTATIONS $\bar{1}$, $\bar{2}$, $\bar{3}$, $\bar{4}$, and $\bar{6}$.

The MIRROR PLANE symmetry operation takes

$$(x, y, z) \rightarrow (x, y, -z), \; (x, -y, z) \rightarrow (x, -y, z),$$

etc., which is equivalent to $\bar{2}$. Invariance under reflection can be denoted $n\sigma_v$ or $n\sigma_h$. The ROTATION symmetry operation for $360°/n$ is denoted n (or C_n). For periodic crystals, CRYSTALLOGRAPHY RESTRICTION allows only 1, 2, 3, 4, and 6.

Symmetry operations can be indicated with symbols such as C_n, S_n, E, i, $n\sigma_v$, and $n\sigma_h$.

1. C_n indicates ROTATION about an n-fold symmetry axis.
2. S_n indicates IMPROPER ROTATION about an n-fold symmetry axis.
3. E (or I) indicates invariance under TRANSLATION.
4. i indicates a center of symmetry under INVERSION.
5. $n\sigma_v$ indicates invariance under n vertical REFLECTIONS.
6. $n\sigma_h$ indicates invariance under n horizontal REFLECTIONS.

Symmetry Principle

SYMMETRIC POINTS are preserved under a MÖBIUS TRANSFORMATION. The SCHWARZ REFLECTION PRINCIPLE is sometimes called the symmetry principle (Needham 2000, p. 252).

See also MÖBIUS TRANSFORMATION, SYMMETRIC POINTS

References

Needham, T. "Analytic Continuation." §5.XI in *Visual Complex Analysis.* New York: Clarendon Press, pp. 247–57, 2000.

Symplectic Diffeomorphism

A MAP $(M_1, \omega_1) \rightarrow (M_2, \omega_2)$ between the SYMPLECTIC MANIFOLDS (M_1, ω_1) and (M_2, ω_2) which is a DIFFEOMORPHISM and $T^*(\omega_2) = (\omega_1)$, where T^* is the PULLBACK MAP induced by T (i.e., the derivative of the DIFFEOMORPHISM T acting on tangent vectors). A symplectic diffeomorphism is also known as a SYMPLECTOMORPHISM or CANONICAL TRANSFORMATION.

See also DIFFEOMORPHISM, PULLBACK MAP, SYMPLECTIC MANIFOLD

References

Guillemin, V. and Sternberg, S. *Symplectic Techniques in Physics.* New York: Cambridge University Press, p. 34, 1984.

Symplectic Form

A symplectic form on a SMOOTH MANIFOLD M is a smooth closed 2-FORM ω on M which is nondegenerate such that at every point m, the alternating bilinear form ω_m on the TANGENT SPACE $T_m M$ is nondegenerate.

A symplectic form on a VECTOR SPACE V over F_q is a function $f(x, y)$ (defined for all $x, y \in V$ and taking values in F_q) which satisfies

$$f(\lambda_1 x_1 + \lambda_2 x_2, y) = \lambda_1 f(x_1, y) + \lambda_2 f(x_2, y),$$

$$f(y, x) = -f(x, y),$$

and

$$f(x, x) = 0.$$

f is called non-degenerate if $f(x, y) = 0$ for all y implies that $x = 0$. Symplectic forms can exist on M (or V) only if M (or V) is EVEN-dimensional. An example of a symplectic form over a vector space is the complex HILBERT SPACE with INNER PRODUCT $\langle \cdots \rangle$ given by

$$f(x, y) = \Im\langle x, y\rangle.$$

See also SYMPLECTIC SPACE, VECTOR SPACE

Symplectic Geometry

References

Symplectic Group

For every even DIMENSION $2n$, the symplectic group $Sp(2n)$ is the GROUP of $2n \times 2n$ MATRICES which preserve a nondegenerate skew symmetric BILINEAR FORM ω, i.e., a SYMPLECTIC FORM.

Every symplectic form can be put into a canonical form by finding a SYMPLECTIC BASIS. So, up to conjugation, there is only one symplectic group, in contrast to the ORTHOGONAL GROUP which preserves a nondegenerate SYMMETRIC BILINEAR FORM. As with the ORTHOGONAL GROUP, the columns of a symplectic matrix form a SYMPLECTIC BASIS.

Since ω^n is a VOLUME FORM, the symplectic group preserves volume and ORIENTATION. Hence, $Sp(2n) \subset SL(2n)$. In fact, $Sp(2)$ is just the group of matrices with DETERMINANT 1. The three symplectic (0,1)-MATRICES are therefore

$$\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}. \tag{1}$$

The matrices

$$\begin{bmatrix} 1 & 0 & 0 & s \\ 0 & 1 & s & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \tag{2}$$

and

$$\begin{bmatrix} \cosh t & \sinh t & 0 & \sinh t \\ \sinh t & \cosh t & \sinh t & 0 \\ 0 & 0 & \cosh t & -\sinh t \\ 0 & 0 & -\sinh t & \cosh t \end{bmatrix} \tag{3}$$

are in $Sp(4)$, where

$$\omega = e_1 \wedge e_3 + e_2 \wedge e_4. \tag{4}$$

In fact, both of these examples are 1-parameter subgroups.

Here is a *Mathematica* function that tests whether a matrix is a symplectic matrix.

```
SymplecticForm[n_Integer]:=
      Join[PadLeft[IdentityMatrix[n],{n,2n}],
PadRight[-IdentityMatrix[n],{n,2n}]]
SymplecticQ[a_List]:=    EvenQ[Length[a]]    &&
Transpose[a].SymplecticForm[Length[a]/2].a
 == SymplecticForm[Length[a]/2]
```

Thinking of a matrix as given by $(2n)^2$ coordinate functions, the set of matrices is identified with $\mathbb{R}^{(2n)^2}$. The symplectic matrices are the solutions to the $(2n)^2$ equations

$$\mathsf{A}^{\mathrm{T}}\ \mathsf{JA} = \mathsf{J}, \tag{5}$$

where J is defined by

$$\omega(x,\ y) = \langle x,\ \mathrm{J}y \rangle. \tag{6}$$

Note that these equations are redundant, since only $2n^2 - n$ of these are independent, leaving $2n^2 + n$ "free" variables. In fact, the symplectic group is a smooth $(2n^2 + n)$-dimensional SUBMANIFOLD of $\mathbb{R}^{2n}$.

Because the symplectic group is a GROUP and a MANIFOLD, it is a LIE GROUP. Its TANGENT SPACE at the identity is the SYMPLECTIC LIE ALGEBRA $\mathfrak{sp}(2n)$. The symplectic group is not COMPACT.

Instead of using real numbers for the coefficients, it is possible to use coefficients from any FIELD F. The symplectic group $Sp_n(q)$ for n EVEN is the GROUP of elements of the GENERAL LINEAR GROUP GL_n that preserve a given nonsingular SYMPLECTIC FORM. Any such MATRIX has DETERMINANT 1.

Wilson, R. A. "ATLAS of Finite Group Representation." http://for.mat.bham.ac.uk/atlas/html/contents.html#symp.

Symplectic Manifold

A pair $(M,\ \omega)$, where M is a MANIFOLD and ω is a SYMPLECTIC FORM on M. The PHASE SPACE $\mathbb{R}^{2n} = \mathbb{R}^n \times \mathbb{R}^n$ is a symplectic manifold. Near every point on a symplectic manifold, it is possible to find a set of local "Darboux coordinates" in which the SYMPLECTIC FORM has the simple form

$$\omega = \sum_k dq_k \wedge\ dp_k$$

(Sjamaar 1996), where $dq_k \wedge\ dp_k$ is a WEDGE PRODUCT.

Symplectic Map

Informally, a symplectic map is a MAP which preserves the sum of AREAS projected onto the set of $(p_2,\ q_2)$ planes. It is the generalization of an AREA-PRESERVING MAP.

Formally, a symplectic map is a real-linear map T that preserves a SYMPLECTIC FORM f, i.e., for which

$$f(Tx,\ Ty) = f(x,\ y)$$

for all x, y. Every symplectic map T on a complex HILBERT SPACE H may be written as $U(\cosh S +$

$J \sinh S$), where U is unitary, S is positive, and J is an anti-linear involution (i.e., complex conjugation).

See also AREA-PRESERVING MAP, LIOUVILLE'S PHASE SPACE THEOREM

Symplectic Space

A real-linear VECTOR SPACE H equipped with a SYMPLECTIC FORM s.

Symplectomorphism

SYMPLECTIC DIFFEOMORPHISM

Synclastic

A surface on which the GAUSSIAN CURVATURE K is everywhere POSITIVE. When K is everywhere NEGATIVE, a surface is called ANTICLASTIC. A point at which the GAUSSIAN CURVATURE is POSITIVE is called an ELLIPTIC POINT.

See also ANTICLASTIC, ELLIPTIC POINT, GAUSSIAN QUADRATURE, HYPERBOLIC POINT, PARABOLIC POINT, PLANAR POINT

Synergetics

Synergetics deals with systems composed of many subsystems which may each be of a very different nature. In particular, synergetics treats systems in which cooperation among subsystems creates organized structure on macroscopic scales (Haken 1993). Examples of problems treated by synergetics include BIFURCATIONS, phase transitions in physics, convective instabilities, coherent oscillations in lasers, nonlinear oscillations in electrical circuits, population dynamics, etc.

See also BIFURCATION, CHAOS, DYNAMICAL SYSTEM

COMMA OF DIDYMUS

Syracuse Algorithm

COLLATZ PROBLEM

Syracuse Problem

COLLATZ PROBLEM

System of Differential Equations

ORDINARY DIFFERENTIAL EQUATION

System of Equations

A *linear* system of equations may be denoted

$$\mathsf{A}\mathbf{X} = \mathbf{Y} \tag{1}$$

where A is a MATRIX and $\mathbf{X}$ and $\mathbf{Y}$ are VECTORS. As shown by CRAMER'S RULE, there is a unique solution if A has a MATRIX INVERSE A^{-1}. In this case,

$$\mathbf{X} = \mathsf{A}^{-1}\mathbf{Y} \tag{2}$$

If $\mathbf{Y} = \mathbf{0}$, then the solution is $\mathbf{X} = \mathbf{0}$. If A has no MATRIX INVERSE, then the solution SUBSPACE is either a LINE or the EMPTY SET. If two equations are multiples of each other, solutions are OF THE FORM

$$\mathbf{X} = \mathbf{A} + t\mathbf{B} \tag{3}$$

for t a REAL NUMBER.

See also CRAMER'S RULE, DETERMINANT, MATRIX INVERSE

Syzygies Problem

The problem of finding all independent irreducible algebraic relations among any finite set of QUANTICS.

See also QUANTIC

Syzygy

A technical mathematical object defined in terms of a POLYNOMIAL RING of n variables over a FIELD k. Syzygies occur in TENSORS at rank 5, 7, 8, and all higher ranks, and play a role in restricting the number of independent ISOTROPIC TENSORS. An example of a rank-5 syzygy is

$$\epsilon_{ijk}\delta_{lm} - \epsilon_{jkl}\delta_{im} + \epsilon_{kli}\delta_{jm} - \epsilon_{lij}\delta_{km} = 0,$$

where ϵ_{ijk} is the PERMUTATION TENSOR and δ_{ij} is the KRONECKER DELTA.

Szemerédi's Theorem

This entry contributed by KEVIN O'BRYANT

Every sequence of integers with positive density contains arbitrarily long ARITHMETIC SEQUENCES.

A corollary states that, for any positive integer k and positive real number δ, there exists a threshold number $n(k, \delta)$ such that for $n \geq n(k, r)$ every subset of $\{1, 2, \ldots, n\}$ with CARDINALITY larger than δn contains a k-term ARITHMETIC SEQUENCE. VAN DER WAERDEN'S THEOREM follows immediately by setting $\delta = n/r$. The best bounds for VAN DER WAERDEN NUMBERS are derived from bounds for $n(k, r)$ in Szemerédi's Theorem.

Szemerédi's theorem was conjectured by Erdos and Turán (1936). Roth (1953) proved the case $k = 3$, and was mentioned in his FIELDS MEDAL citation. Szemerédi (1969) proved the case $k = 4$, and the general theorem in 1975 as a consequence of SZEMERÉDI'S REGULARITY LEMMA (Szemerédi 1975a), for which he collected a $1000 prize from Erdos. Fürstenberg and Katznelson (1979) proved Szemerédi's theorem using ERGODIC THEORY. Gowers (1998ab) subsequently gave a new proof, with a better bound on $n(k, r)$, for the case $k = 4$ (mentioned in *his* FIELDS MEDAL citation; Lepowsky *et al.* 1999).

Erdos offered a $3,000 prize for a proof of the proposition that "If the sum of reciprocals of a set of integers diverges, then that set contains arbitrarily long arithmetic progressions." This conjecture is still open (unsolved), even for 3-term arithmetic progressions. Erdos also offered $10,000 for an asymptotic formula for $\rho_3(n)$, the largest possible cardinality of a subset of $\{1, 2, \ldots, n\}$ that does not contain a 3-term arithmetic progression.

Szilassi Polyhedron

A HEPTAHEDRON which is topologically equivalent to a TORUS and for which every pair of faces has an EDGE in common. The Szilassi polyhedron has 14 VERTICES, seven faces, and 21 EDGES, and is the DUAL POLYHEDRON of the CSÁSZÁR POLYHEDRON. This polyhedron was discovered by L. Szilassi in 1977. In the above illustration of the net, sides indicated by letters are connected with the corresponding side indicated by the same letter but with a different number of primes. Like the TETRAHEDRON, each face of the Szilassi polyhedron touches all other faces.

The SKELETON of the Szilassi polyhedron is equivalent to the HEAWOOD GRAPH, shown above.

T

T2-Separation Axiom

Given any two distinct points x, y, there exist neighborhoods u and v of x and y, respectively, with $u \cap v = \emptyset$. It then follows that finite SUBSETS are CLOSED.

See also CLOSURE (SET)

Tableau

YOUNG TABLEAU

Tableau Class

When a YOUNG TABLEAU is constructed using the so-called insertion algorithm, an element starts in some position on the first row, from which it may later be bumped. In contrast, the elements that start out in the ith column are said to belong to the ith class (Skiena 1990, p. 73). Tableau classes may be computed using `TableauClasses[p]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`).

Tacnode

A DOUBLE POINT at which two OSCULATING CURVES are TANGENT. The above plot shows the tacnode of the curve $2x^4 - 3x^2y + y^2 - 2y^3 + y^4 = 0$. The LINKS CURVE also has a tacnode at the origin.

Tacpoint

A tangent point of two similar curves.

Tactix

NIM

Tail Probability

Define T as the set of all points t with probabilities $P(x)$ such that $a > t \Rightarrow P(a \le x \le a + da) < P_0$ or $a < t \Rightarrow P(a \le x \le a + da) < P_0$, where P_0 is a POINT PROBABILITY (often, the likelihood of an observed event). Then the associated tail probability is given by $\int_T P(x)\,dx$.

See also P-VALUE, POINT PROBABILITY

Tait Coloring

A 3-coloring of GRAPH EDGES so that no two EDGES of the same color meet at a VERTEX (Ball and Coxeter 1987, pp. 265–266).

See also EDGE (GRAPH), TAIT CYCLE, VERTEX (GRAPH)

References

Ball, W. W. R. and Coxeter, H. S. M. *Mathematical Recreations and Essays, 13th ed.* New York: Dover, 1987.

Tait Cycle

A set of circuits going along the EDGES of a GRAPH, each with an EVEN number of EDGES, such that just one of the circuits passes through each VERTEX (Ball and Coxeter 1987, pp. 265–266).

Tait Flyping Conjecture

FLYPING CONJECTURE

Tait's Hamiltonian Graph Conjecture

Every 3-connected CUBIC GRAPH has a HAMILTONIAN CIRCUIT. Proposed by Tait in 1880 and refuted by Tutte (1946) with the counterexample now known as TUTTE'S GRAPH. Had the conjecture been true, it would have implied the FOUR-COLOR THEOREM. A simpler counterexample was later given by Kozyrev and Grinberg.

Tait's Knot Conjectures

P. G. Tait undertook a study of KNOTS in response to Kelvin's conjecture that the atoms were composed of knotted vortex tubes of ether (Thomson 1869). He categorized KNOTS in terms of the number of crossings in a plane projection. He also made some conjectures which remained unproven until the discovery of JONES POLYNOMIALS:

1. Reduced alternating diagrams have minimal CROSSING NUMBER,
2. Any two reduced alternating diagrams of a given knot have equal WRITHE,
3. The FLYPING CONJECTURE, which states that the number of crossings is the same for any diagram of an ALTERNATING KNOT.

Conjectures (1) and (2) were proved by Kauffman (1987), Murasugi (1987ab), and Thistlethwaite (1987, 1988) using properties of the JONES POLYNOMIAL or KAUFFMAN POLYNOMIAL F (Hoste *et al.* 1998). Conjecture (3) was proved true by Menasco and Thistlethwaite (1991, 1993) using properties of the JONES POLYNOMIAL (Hoste *et al.* 1998).

TAK Function

A RECURSIVE FUNCTION devised by I. Takeuchi. For INTEGERS x, y, and z, and a function h, it is

$$\mathrm{TAK}_h(x,\ y,\ z)$$

The number of function calls $F_0(a,\ b)$ required to compute $\mathrm{TAK}_0(a,\ b,\ 0)$ for $a > b > 0$ is

$$F_0(a,\ b) = 4\sum_{k=0}^{b} \frac{a-b}{a+b-2k}\binom{a+b-2k}{b-k} - 3$$

$$= 1 + 4\sum_{k=0}^{b-1} \frac{a-b}{a+b-2k}\binom{a+b-2k}{b-k}$$

(Vardi 1991).

The TAK function is also connected with the BALLOT PROBLEM (Vardi 1991).

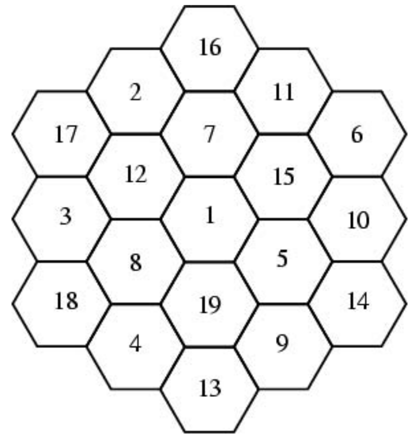
Talbot's Curve

A curve investigated by Talbot which is the NEGATIVE PEDAL CURVE of an ELLIPSE with respect to its center. It has four CUSPS and two NODES, provided the ECCENTRICITY of the ELLIPSE is greater than $1/\sqrt{2}$. Its CARTESIAN EQUATION is

$$x = \frac{(a^2 + f^2 \sin^2 t) \cos t}{a}$$

$$y = \frac{(a^2 - 2f^2 + f^2 \sin^2 t) \sin t}{b},$$



where f is a constant.

Talisman Hexagon

An (n, k)-talisman hexagon is an arrangement of nested hexagons containing the integers 1, 2, ..., $H_n = 3n(n-1)+1$, where H_n is the nth HEX NUMBER, such that the difference between all adjacent hexagons is at least as large as a number k. The hexagon illustrated above is a (3, 4)-talisman hexagon.

Tame Algebra

Let A denote an $\mathbb{R}$-algebra, so that A is a VECTOR SPACE over R and

$$A \times A \to A$$

$$(x,\ y) \mapsto x \cdot y,$$

where $x \cdot y$ is VECTOR MULTIPLICATION which is assumed to be BILINEAR. Now define

$$Z \equiv \{x \in a : x \cdot y - 0 \text{ for some nonzero } y \in A\},$$

where $0 \in Z$. A is said to be tame if Z is a finite union of SUBSPACES of A. A 2-D 0-ASSOCIATIVE algebra is tame, but a 4-D 4-ASSOCIATIVE algebra and a 3-D 1-ASSOCIATIVE algebra need not be tame. It is conjectured that a 3-D 2-ASSOCIATIVE algebra is tame, and proven that a 3-D 3-ASSOCIATIVE algebra is tame if it possesses a multiplicative IDENTITY ELEMENT.

References
Finch, S. "Zero Structures in Real Algebras." http://www.mathsoft.com/asolve/zerodiv/zerodiv.html.

Tame Knot

A KNOT equivalent to a POLYGONAL KNOT. Knots which are not tame are called WILD KNOTS.

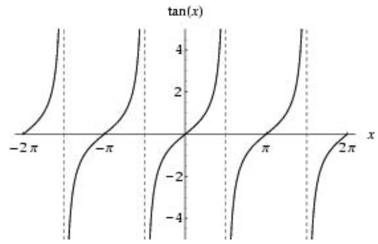
Tan



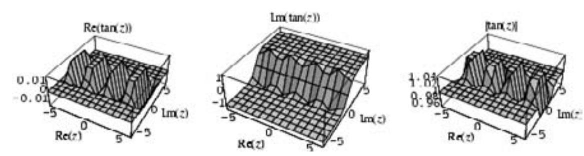
TANGENT

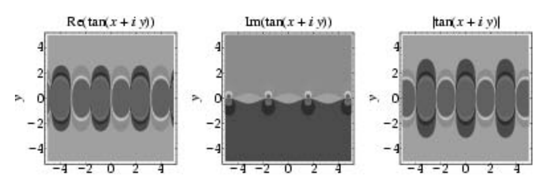
Tangency Theorem

The external (internal) SIMILARITY POINT of two fixed CIRCLES is the point at which all the CIRCLES homogeneously (nonhomogeneously) tangent to the fixed CIRCLES have the same POWER and at which all the tangency secants intersect.

References
Dörrie, H. *100 Great Problems of Elementary Mathematics: Their History and Solutions.* New York: Dover, p. 157, 1965.

Tangent





The tangent function is defined by

$$\tan x \equiv \frac{\sin x}{\cos x}, \tag{1}$$

where $\sin x$ is the SINE function and $\cos x$ is the COSINE function. The notation $\operatorname{tg} x$ is sometimes also used (Gradshteyn and Ryzhik 2000, p. xxix).

The word "tangent" also has an important related meaning as a LINE or PLANE which touches a given curve or solid at a single point. These geometrical objects are then called a TANGENT LINE or TANGENT PLANE, respectively.

The definition of the tangent function can be extended to complex arguments z using the definition

$$\tan z = \frac{e^{iz} - e^{-iz}}{i(e^{iz} + e^{-iz})}, \tag{2}$$

where E is the base of the NATURAL LOGARITHM and I is the IMAGINARY NUMBER. A related function known as the HYPERBOLIC TANGENT is similarly defined,

$$\tanh z = \frac{e^{z} - e^{-z}}{e^{z} + e^{-z}}. \tag{3}$$

Important tangent identities include

$$\tan^2 \theta + 1 = \sec^2 \theta \tag{4}$$

$$\tan(\alpha + \beta) = \frac{\tan \alpha + \tan \beta}{1 - \tan \alpha \tan \beta} \tag{5}$$

$$\tan(\alpha - \beta) = \frac{\tan \alpha - \tan \beta}{1 + \tan \alpha \tan \beta} \tag{6}$$

$$\tan(2\alpha) = \frac{2\tan\alpha}{1-\tan^2\alpha}. \quad (7)$$

$$\tan(n\alpha) = \frac{\tan[(n-1)\alpha] + \tan\alpha}{1-\tan[(n-1)\alpha]\tan\alpha} \quad (8)$$

$$\tan\left(\frac{\alpha}{2}\right) = \frac{\sin\alpha}{1+\cos\alpha} \quad (9)$$

$$= \frac{1-\cos\alpha}{\sin\alpha} \quad (10)$$

$$= \frac{1 \pm \sqrt{1+\tan^2\alpha}}{\tan\alpha} \quad (11)$$

$$= \frac{\tan\alpha\sin\alpha}{\tan\alpha + \sin\alpha} \quad (12)$$

in addition to the beautiful identity

$$\tan(\alpha+\beta+\gamma) = \frac{\tan\alpha + \tan\beta + \tan\gamma - \tan\alpha\tan\beta\tan\gamma}{1-\tan\beta\tan\gamma - \tan\gamma\tan\alpha - \tan\alpha\tan\beta}. \quad (13)$$

There are a number of simple but interesting tangent identities based on those given above, including

$$\tan(A+60^\circ)\tan(A-60^\circ) + \tan A\tan(A+60^\circ) + \tan A\tan(A-60^\circ) = -3 \quad (14)$$

(Borchardt and Perrott 1930).

The MACLAURIN SERIES valid for $-\pi/2 < x < \pi/2$ for the tangent function is

$$\tan x = \sum_{n=0}^{\infty} \frac{(-1)^{n-1}2^{2n}(2^{2n}-1)B_{2n}}{(2n)!} x^{2n-1} + \ldots$$

$$= x + \tfrac{1}{3}x^3 + \tfrac{2}{15}x^5 + \tfrac{17}{315}x^7 + \tfrac{62}{2835}x^9 + \ldots, \quad (15)$$

where B_n is a BERNOULLI NUMBER.

$\tan x$ is IRRATIONAL for any RATIONAL $x \neq 0$, which can be proved by writing $\tan x$ as a CONTINUED FRACTION

$$\tan x = \cfrac{x}{1 - \cfrac{x^2}{3 - \cfrac{x^2}{5 - \cfrac{x^2}{7 - \ldots}}}}. \quad (16)$$

Lambert derived another CONTINUED FRACTION expression for the tangent,

$$\tan x = \cfrac{1}{\cfrac{1}{x} - \cfrac{1}{\cfrac{3}{x} - \cfrac{1}{\cfrac{5}{x} - \cfrac{1}{\cfrac{7}{x} - \ldots}}}}. \quad (17)$$

An interesting identity involving the PRODUCT of tangents is

$$\prod_{k=1}^{\lfloor (n-1)/2 \rfloor} \tan\left(\frac{k\pi}{n}\right) = \begin{cases} \sqrt{n} & \text{for } n \text{ odd} \\ 1 & \text{for } n \text{ even,} \end{cases} \quad (18)$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION. Another tangent identity is

$$\tan(n\tan^{-1}x) = \frac{1}{i}\frac{(1+ix)^n - (1-ix)^n}{(1+ix)^n + (1-ix)^m} \quad (19)$$

(Beeler *et al.* 1972).

The equation

$$x = \tan x \quad (20)$$

does not have simple closed-form solutions, but the first few approximate numerical solutions are 0, 4.49341, 7.72525, 10.9041, 14.0662, ... The difference between consecutive solutions gets closer and closer to π for higher order solutions.

Tangent Bifurcation

FOLD BIFURCATION

Tangent Bundle

Every smooth manifold M has a tangent bundle TM, which consists of the TANGENT SPACE TM_p at all points p in M. Since a tangent space TM_p is the set of all tangent vectors to M at p, the tangent bundle is the collection of all tangent vectors, along with the

information of the point to which they are tangent.

$$TM = \{(p,\ v) : p \in M,\ v \in TM_p\}$$

The tangent bundle is a special case of a VECTOR BUNDLE. As a bundle it has RANK n, where n is the dimension of M. A COORDINATE CHART on M provides a TRIVIALIZATION for TM. In the coordinates, $(x_1, \ldots, x_n)$, the vector fields $(v_1, \ldots, v_n)$, where $v_i = \partial/\partial x_i$, span the tangent vectors at every point (in the COORDINATE CHART). The transition function from these coordinates to another set of coordinates is given by the JACOBIAN of the coordinate change.

For example, on the UNIT SPHERE, at the point (1, 0, 0) there are two different coordinate charts defined on the same HEMISPHERE, $\phi : U_1 \to S^2$ and $\psi : U_2 \to S^2$,

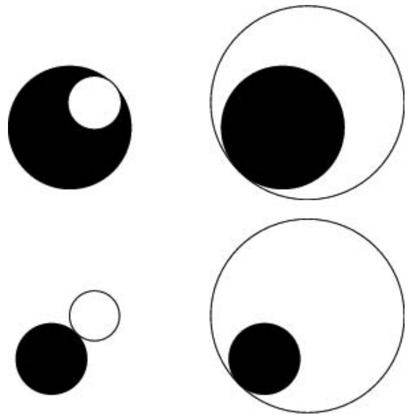
$$\phi(x_1,\ x_2) = (\cos x_1 \cos x_2,\ \sin x_1 \cos x_2,\ \sin x_2) \quad (1)$$

$$\psi(y_1,\ y_2) = \left(\sqrt{1 - y_1^2 - y_2^2},\ y_1,\ y_1\right) \quad (2)$$

with $U_1 = (-\pi/2,\ \pi/2) \times (-\pi/2,\ \pi/2)$ and $U_2 = \{(y_1,\ y_2) : y_1^2 + y_2^2 < 1\}$. The map between the coordinate charts is $\alpha = \psi^{-1} \circ \phi$.

$$(y_1,\ y_2) = \alpha(x_1,\ x_2) = (\sin x_1,\ \cos x_2,\ \sin x_2) \quad (3)$$

The JACOBIAN of $\alpha : U_1 \to U_2$ is given by the matrix-valued function



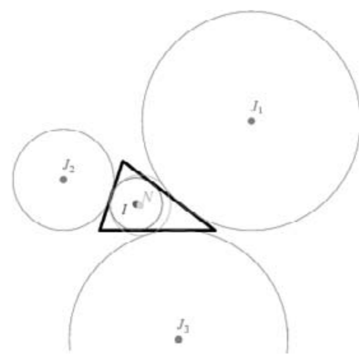
$$\begin{bmatrix} \cos x_1 \cos x_2 & \sin x_1 \sin x_2 \\ 0 & \cos x_2 \end{bmatrix} \quad (4)$$

which has DETERMINANT $\cos x_1 \cos^2 x_2$ and so is invertible on U_1.

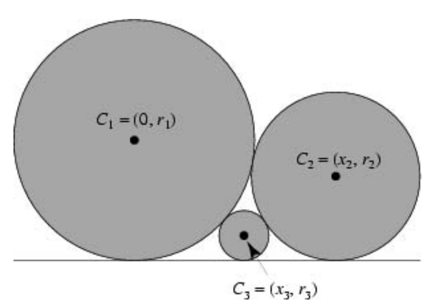
The tangent vectors transform by the Jacobian. At the point $(x_1,\ x_2)$ in U_1, a tangent vector v corresponds to the tangent vector Jv at $\alpha(x_1,\ x_2)$ in U_2. These two are just different versions of the same element of the tangent bundle.

See also CALCULUS, COORDINATE CHART, COTANGENT BUNDLE, DIRECTIONAL DERIVATIVE, EUCLIDEAN SPACE, JACOBIAN, MANIFOLD, TANGENT BUNDLE, TANGENT SPACE, TANGENT VECTOR, VECTOR FIELD, VECTOR SPACE

Tangent Circles



Two circles with centers at $(x_i,\ y_i)$ with radii r_i for $i = 1,\ 2$ are mutually tangent if



$$(x_1 - x_2)^2 + (y_1 - y^2)^2 = (r_1 \pm r_2)^2.$$

If the center of the second circle is inside the first, then the $-$ and $+$ signs both correspond to internally tangent circles. If the center of the second circle is outside the first, then the $-$ sign corresponds to externally tangent circles and the $+$ sign to internally tangent circles.

Finding the circles tangent to three given circles is known as APOLLONIUS' PROBLEM.

There are four CIRCLES that are tangent all three sides (or their extensions) of a given TRIANGLE: the INCIRCLE I and three EXCIRCLES J_1, J_2, and J_3. These four circles are, in turn, all touched by the NINE-POINT CIRCLE N.

If two circles C_1 and C_2 of radii r_1 and r_2 are mutually

tangent to each other and a line, then their centers are separated by a horizontal distance given by solving

$$x_2^2 + (r_1 - r_2)^2 = (r_1 + r_2)^2 \quad (1)$$

for x_2, giving

$$x_2 = 2\sqrt{r_1 r_2}. \quad (2)$$

The position and radius of a third circle tangent to the first two and the line can be found by solving the simultaneous equations

$$x_3^2 + (r_1 - r_3)^2 = (r_1 + r_3)^2 \quad (3)$$

$$(x_3 - x_2)^2 + (r_2 - r_3)^2 = (r_2 + r_3)^2 \quad (4)$$

for x_3 and r_3, giving

$$x_3 = \frac{2r_1\sqrt{r_2}}{\sqrt{r_1} + \sqrt{r_2}} \quad (5)$$

$$r_3 = \frac{r_1 r_2}{\left(\sqrt{r_1} + \sqrt{r_2}\right)^2}. \quad (6)$$

The latter equation can be written in the form

$$\frac{1}{\sqrt{r_3}} = \frac{1}{\sqrt{r_1}} + \frac{1}{\sqrt{r_2}}. \quad (7)$$

This problem was given as a Japanese temple problem on a tablet from 1824 in the Gumma Prefecture (Rothman 1998).

Tangent Developable

A ruled surface M is a tangent developable of a curve $\mathbf{y}$ if M can be parameterized by $\mathbf{x}(u, v) = \mathbf{y}(u) + v\mathbf{y}'(u)$. A tangent developable is a flat surface.

Tangent Map

If $f: M \to N$, then the tangent map Tf associated to f is a VECTOR BUNDLE HOMEOMORPHISM $Tf: TM \to TN$ (i.e., a MAP between the TANGENT BUNDLES of M and N respectively). The tangent map corresponds to DIFFERENTIATION by the formula

$$Tf(v) = (f \circ \phi)'(0), \quad (1)$$

where $\phi'(0) = v$ (i.e., ϕ is a curve passing through the base point to v in TM at time 0 with velocity v). In this case, if $f: M \to N$ and $g: N \to O$, then the CHAIN RULE is expressed as

$$T(f \circ g) = Tf \circ Tg. \quad (2)$$

In other words, with this way of formalizing differentiation, the CHAIN RULE can be remembered by saying that "the process of taking the tangent map of a map is functorial." To a topologist, the form

$$(f \circ g)'(a) = f'(g(a)) \circ g'(a), \quad (3)$$

for all a, is more intuitive than the usual form of the CHAIN RULE.

Tangent Plane

Let (x_0, y_0) be any point of a surface function $z = f(x, y)$. Then the surface has a nonvertical tangent plane at (x_0, y_0) with equation

$$z = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0).$$

See also NORMAL VECTOR, PLANE, TANGENT, TANGENT LINE, TANGENT SPACE, TANGENT VECTOR

Tangent Space

Let x be a point in an n-dimensional COMPACT MANIFOLD M, and attach at x a copy of $\mathbb{R}^n$ tangential to M. The resulting structure is called the TANGENT SPACE of M at x and is denoted T_xM. If γ is a smooth curve passing through x, then the derivative of γ at x is a VECTOR in T_xM.

See also TANGENT, TANGENT BUNDLE, TANGENT PLANE, TANGENT SPACE (CHART), TANGENT SPACE (SUBMANIFOLD), TANGENT VECTOR

Tangent Space (Chart)

From the point of view of COORDINATE CHARTS, the notion of tangent space is quite simple. The tangent space consists of all directions, or velocities, a particle can take. In an open set U in $\mathbb{R}^n$ there are no constraints, so the tangent space at a point p is another copy of $\mathbb{R}^n$. The set U could be a COORDINATE CHART for an n-dimensional MANIFOLD.

The tangent space at p, denoted TM_p, is the set of possible VELOCITY VECTORS of paths through p. Hence there is a CANONICAL BASIS: if $(x_1, \ldots, x_n)$ are the coordinates, then $v_1, \ldots, v_n$ are a basis for the tangent space, where v_i is the velocity vector of a particle with unit speed moving inward along the coordinate x_i. The collection of tangent vectors, called the TANGENT BUNDLE, is the PHASE SPACE of a single particle moving in the manifold M.

It seems as if the tangent space at p is the same as the tangent space at all other points in the chart U. However, while they do share the same dimension and are ISOMORPHIC, in a change of coordinates, they lose their canonical isomorphism.

For example, let $U = (0, 1)$ and $V = (0, 3)$ be coordinate charts for the unit interval I. We can change coordinates with $\phi: U \to V$ defined by $\phi(x) = x + 2x^2$. This is a change of coordinates because the derivative does not vanish on U. But this change is not linear, and stretches out I more near 1 than it does near 0. The tangent vectors transform by the derivative. At $x = 1/4$, they are stretched by a factor of $d\phi/dx = 2$. While at $x = 3/4$, they are stretched out by a factor of $d\phi/dx = 4$.

In general, the tangent vectors transform according to the JACOBIAN. The tangent vector v at q can also be considered as the tangent vector $J_\phi v$ at $\phi(q)$ in another coordinate chart, where ϕ is the DIFFEOMORPHISM from one chart to the other. The linear transformation determined by the JACOBIAN of ϕ is invertible, since ϕ is a DIFFEOMORPHISM.

Not only does the JACOBIAN, and the CHAIN RULE, show that the tangent space is WELL DEFINED, independent of coordinate chart, but it also shows that tangent vectors "push forward." That is, given

any smooth map $f: X \to Y$ between manifolds, it makes sense to map the tangent vectors of X to tangent vectors of Y. Writing $\tilde{f}$ as the function f between a coordinate chart in X and one in Y, then $f_*(v) = J_{\tilde{f}}(v)$ maps v from TX_p to $TY_{f(p)}$. Another notation for f_* is df, the DIFFERENTIAL of f. In the language of TENSORS, the tangent vector's pushing forward means that a vector field is a COVARIANT TENSOR.

Tangent Space (Intrinsic)

The tangent space at a point p in an ABSTRACT MANIFOLD M can be described without the use of embeddings or COORDINATE CHARTS. The elements of the tangent space are called tangent vectors, and the collection of tangent spaces forms the TANGENT BUNDLE.

One description is to put an equivalence relation on smooth paths through the point p. More precisely, consider all smooth maps $f: I \to M$ where $I = (-1, 1)$ and $f(0) = p$. We say that two maps f and g are equivalent if they agree to first order. That is, in any coordinate chart around p, $f'(0) = g'(0)$. If they are similar in one chart then they are similar in any other chart, by the CHAIN RULE. The notion of agreeing to first order depends on coordinate charts, but this cannot be completely eliminated since that is how manifolds are defined.

Another way is to first define a VECTOR FIELD as a DERIVATION of the ring of smooth functions $f: M \to \mathbb{R}$. Then a tangent vector at a point p is an equivalence class of vector fields which agree at p. That is, $X \sim Y$ if $Xf(p) = Yf(p)$ for every smooth function f. Of course, the tangent space at p is the vector space of tangent vectors at p. The only drawback to this version is that a COORDINATE CHART is required to show that the tangent space is an n-dimensional vector space.

See also CHAIN RULE, COORDINATE CHART, DERIVATION ALGEBRA, DIFFERENTIAL FORM, DIRECTIONAL DERIVATIVE, EXTERIOR ALGEBRA, EUCLIDEAN SPACE, JACOBIAN, LIE GROUP, MANIFOLD, SHEAF, TANGENT BUNDLE, TANGENT SPACE, VECTOR FIELD, VELOCITY VECTOR

Tangent Space (Submanifold)

The TANGENT PLANE to a surface at a point p is the tangent space at p (after translating to the origin). The elements of the tangent space are called TANGENT VECTORS, and they are CLOSED under addition and scalar multiplication. In particular, the tangent space is a VECTOR SPACE.

Any SUBMANIFOLD of EUCLIDEAN SPACE, and more generally any SUBMANIFOLD of an ABSTRACT MANIFOLD, has a tangent space at each point. The collection of tangent spaces TM_p to M forms the TANGENT BUNDLE $TM = \cup_{p \in M} (p, TM_p)$. A VECTOR FIELD assigns to every point p a TANGENT VECTOR in the tangent space at p.

There are two ways of defining a submanifold, and each way gives rise to a different way of defining the tangent space. The first way uses a PARAMETERIZATION, and the second way uses a system of equations.

Suppose that $f = (f_1, \ldots, f_n)$ is a local PARAMETERIZATION of a SUBMANIFOLD M in EUCLIDEAN SPACE $\mathbb{R}^n$. Say,

$$f: U \to \mathbb{R}^n, \tag{1}$$

where U is the open UNIT BALL in $\mathbb{R}^k$, and $f(U) \subset M$. At the point $p = f(0)$, the tangent space is the image of the JACOBIAN of f, as a linear transformation from $\mathbb{R}^k$ to $\mathbb{R}^n$. For example, consider the UNIT SPHERE

$$\mathbb{S}^2 = \{(y_1, y_2, y_3) : y_1^2 + y_2^2 + y_3^2 = 1\} \tag{2}$$

in $\mathbb{R}^3$. Then the function (with the domain $U = \{(x_1, x_2) : x_1^2 + x_2^2 < 1\}$)

$$f = \left(x_1, x_2, \sqrt{1 - x_1^2 - x_2^2}\right) \tag{3}$$

parameterizes a NEIGHBORHOOD of the north pole. Its Jacobian at $(0, 0)$ is given by the matrix

$$\begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{bmatrix} \tag{4}$$

whose IMAGE is the tangent space at p,

$$TS^2|_{(0, 0, 1)} = \{(a, b, 0)\}. \tag{5}$$

An alternative description of a SUBMANIFOLD M as the set of solutions to a system of equations leads to another description of tangent vectors. Consider a SUBMANIFOLD M which is the set of solutions to the system of equations

$$\begin{gathered} f_1(x_1, \ldots, x_n) = 0 \\ \vdots \\ f_r(x_1, \ldots, x_n) = 0, \end{gathered} \tag{6}$$

where $k + r = n$ and the JACOBIAN of $f: \mathbb{R}^n \to \mathbb{R}^r$, with $f = (f_1, \ldots f_n)$, has rank r at the solutions M to $f = 0$. A tangent vector v at a solution p is an infinitesimal solution to the above equations (at p). The tangent vector $v = (v_1, \ldots, v_n)$ is a solution of the derivative (linearization) of f, i.e., it is in the NULLSPACE of the JACOBIAN.

Consider this method in the recomputation the tangent space of the sphere at the North Pole. The sphere is two-dimensional and is described as the

solution to single equation $(3-2=1)$ $x_1^2+x_2^2+x_3^2=1$. Set $f_1=x_1^2+x_2^2+x_3^2-1$. We want to compute the tangent space at the solution $f_1(0,\ 0,\ 1)=0$ (at the north pole). The JACOBIAN at this point is the 1×3 matrix $[0,\ 0,\ 2]$, and its nullspace is the tangent space

$$TS^2|_{(0,\ 0,\ 1)}=\{(a,\ b,\ 0)\}. \quad (7)$$

It appears that the tangent space depends either on the choice of parametrization, or on the choice of system of equations. Because the Jacobian of a composition of functions obeys the CHAIN RULE, the tangent space is WELL DEFINED. Note that the JACOBIAN of a DIFFEOMORPHISM is an INVERTIBLE LINEAR MAP, and these correspond to the ways the equations can be changed. The basic facts from LINEAR ALGEBRA used to show that the tangent space is WELL DEFINED are the following.

1. If $A:\mathbb{R}^k\to\mathbb{R}^k$ is invertible, then the image of $B:\mathbb{R}^k\to\mathbb{R}^n$ is the same as the image of AB.
2. If $A:\mathbb{R}^n\to\mathbb{R}^n$ is invertible, then the nullspace of $B:\mathbb{R}^n\to\mathbb{R}^r$ is the same as the nullspace of BA. More precisely, $\mathrm{Null}(BA)=A^{-1}(\mathrm{Null}(B))$.

These techniques work in any dimension. In addition, they generalize to submanifolds of an ABSTRACT MANIFOLD, because tangent vectors depend on local properties. In particular, the tangent space can be computed in any coordinate chart, because any change in COORDINATE CHART corresponds to a DIFFEOMORPHISM in Euclidean space.

The tangent space can give some geometric insight to higher-dimensional phenomena. For example, to compute the tangent space to the FLAT TORUS (donut) M in $\mathbb{R}^4$, note that it can be parametrized, by

$$f(x_1,\ x_2)=(\sin x_1,\ \cos x_1,\ \sin x_2,\ \cos x_2) \quad (8)$$

with domain $U=\{(x_1,\ x_2): x_1^2+x_2^2<1\}$, near the point $p=f(0,\ 0)=(0,\ 1,\ 0,\ 1)$. Its JACOBIAN at p is the matrix

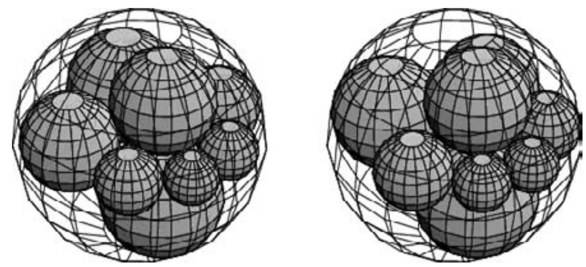
$$\begin{bmatrix}1 & 0\\ 0 & 0\\ 0 & 1\\ 0 & 0\end{bmatrix}, \quad (9)$$

whose image is the tangent space $TM|_p=\{(a,\ 0,\ b,\ 0)\}$.

Alternatively, M is the set of solutions to equations

$$f_1(x_1,\ x_2, x_3,\ x_4)=x_1^2+x_2^2-1=0 \quad (10)$$

$$f_2(x_1,\ x_2, x_3,\ x_4)=x_3^2+x_4^2-1=0. \quad (11)$$



The Jacobian at the solution $p=(0,\ 1,\ 0,\ 1)$ is the matrix

$$\begin{bmatrix}0 & 2 & 0 & 0\\ 0 & 0 & 0 & 2\end{bmatrix}, \quad (12)$$

whose NULLSPACE is the tangent space $TM|_p=\{(a,\ 0,\ b,\ 0)\}$.

Tangent Spheres

A special case of tangent spheres is given by Soddy's hexlet, which consists of a chain of six spheres externally tangent to two mutually tangent spheres and internally tangent to a circumsphere. The bends of the circles in the chain obey the relationship

$$\frac{1}{r_1}+\frac{1}{r_4}=\frac{1}{r_2}+\frac{1}{r_3}=\frac{1}{r_3}+\frac{1}{r_6}. \quad (1)$$

A SANGAKU PROBLEM from 1798 asks to distribute 30 identical spheres of radius r such that they are tangent to a single central sphere of radius R and to four other small spheres. This can be accomplished (left figure) by placing the spheres at the vertices of an ICOSIDODECAHEDRON (right figure) of side length a, where the radii r and R are given by

$$r=\tfrac{1}{2}a \quad (2)$$

$$R=\tfrac{1}{2}\sqrt{5}a \quad (3)$$

(Rothman 1998).

In general, the BENDS of five mutually tangent spheres are related by

$$3(\kappa_1^2+\kappa_2^2+\kappa_3^2+\kappa_4^2+\kappa_5^2) = (\kappa_1+\kappa_2+\kappa_3+\kappa_4+\kappa_5)^2. \quad (4)$$

Solving for κ_5 gives

$$\kappa_5^\pm = \tfrac{1}{2}\{\kappa_1+\kappa_2+\kappa_3+\kappa_4 \pm[6(\kappa_1\kappa_2+\kappa_1\kappa_3+\kappa_1\kappa_4+\kappa_2\kappa_3+\kappa_2\kappa_4+\kappa_3\kappa_4) -3(\kappa_1^2+\kappa_2^2+\kappa_3^2+\kappa_4^2)]^{1/2}\}. \quad (5)$$

(Soddy 1937a). Gosset (1937) pointed out that the expression under the square root sign is given by

$$\{6(\kappa_1\kappa_2+\kappa_1\kappa_3+\kappa_1\kappa_4+\kappa_2\kappa_3+\kappa_2\kappa_4+\kappa_3\kappa_4) -3(\kappa_1^2+\kappa_2^2+\kappa_3^2+\kappa_4^2)\}^{1/2} = 3\sqrt{3}V\kappa_1\kappa_2\kappa_3\kappa_4, \quad (6)$$

where V is the VOLUME of the TETRAHEDRON having vertices at the centers of the corresponding four spheres. Therefore, the equation for κ_5 can be written simplify as

$$\kappa_5 = \tfrac{1}{2}\sigma_2 + \sqrt{3}\epsilon, \quad (7)$$

where

$$\sigma = \kappa_1+\kappa_2+\kappa_3+\kappa_4 \quad (8)$$

$$\epsilon = \tfrac{3}{2}V\kappa_1\kappa_2\kappa_3\kappa_4. \quad (9)$$

(Soddy 1937b).

In addition, the tetrahedra formed by joining the four points of contact of any one sphere with the other four (when all five are in mutual contact) have opposite edges whose product is the constant

$$4\sqrt{(\kappa_1+\kappa_5)(\kappa_2+\kappa_5)(\kappa_3+\kappa_5)(\kappa_4+\kappa_5)} \quad (10)$$

and the volume of these tetrahedra is

$$V = \frac{2}{\sqrt{3}}\frac{\kappa_5}{(\kappa_1+\kappa_5)(\kappa_2+\kappa_5)(\kappa_3+\kappa_5)(\kappa_4+\kappa_5)} \quad (11)$$

(Soddy 1937b). Gosper has further extended this result to $n+2$ mutually tangent n-D HYPERSPHERES, whose CURVATURES satisfy

$$\left(\sum_{i=0}^{n+1}\kappa_i\right)^2 - n\sum_{i=0}^{n+1}\kappa_i^2 = 0. \quad (12)$$

Solving for κ_{n+1} gives

$$\kappa_{n+1} = \frac{\sqrt{n}\sqrt{\left(\sum_{i=0}^n \kappa_i\right)^2 - (n-1)\sum_{i=0}^n \kappa_i^2} + \sum_{i=0}^n \kappa_i}{n-1}. \quad (13)$$

For (at least) $n=2$ and 3, the RADICAL equals

$$f(n)V\kappa_0\kappa_1\cdots\kappa_n, \quad (14)$$

where V is the CONTENT of the SIMPLEX whose vertices are the centers of the $n+1$ independent HYPERSPHERES. The RADICAND can also become NEGATIVE, yielding an IMAGINARY κ_{n+1}. For $n=3$, this corresponds to a sphere touching three large bowling balls and a small BB, all mutually tangent, which is an impossibility.

Tangent Vector

For a curve with POSITION VECTOR $\mathbf{r}(t)$, the unit tangent vector $\hat{\mathbf{T}}(t)$ is defined by

$$\hat{\mathbf{T}}(t) \equiv \frac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} = \frac{\frac{d\mathbf{r}}{dt}}{\left|\frac{d\mathbf{r}}{dt}\right|} \quad (1)$$

$$= \frac{\frac{d\mathbf{r}}{dt}}{\frac{ds}{dt}} \quad (2)$$

$$= \frac{d\mathbf{r}}{ds}, \quad (3)$$

where t is a parameterization variable and s is the ARC LENGTH. For a function given parametrically by $(f(t), g(t))$, the tangent vector relative to the point $(f(t), g(t))$ is therefore given by

$$x(t) = \frac{f'}{\sqrt{f'^2+g'^2}} \quad (4)$$

$$y(t) = \frac{g'}{\sqrt{f'^2+g'^2}}. \quad (5)$$

To actually place the vector tangent to the curve, it must be displaced by $(f(t), g(t))$. It is also true that

$$\frac{d\hat{\mathbf{T}}}{ds} = \kappa\hat{\mathbf{N}} \quad (6)$$

$$\frac{d\hat{\mathbf{T}}}{dt} = \kappa\frac{ds}{dt}\hat{\mathbf{N}} \quad (7)$$

$$[\dot{\mathbf{T}}, \ddot{\mathbf{T}}, \dddot{\mathbf{T}}] = \kappa^5\frac{d}{ds}\left(\frac{\tau}{\kappa}\right), \quad (8)$$

where $\mathbf{N}$ is the NORMAL VECTOR, κ is the CURVATURE, and τ is the TORSION.

Gray, A. "Tangent and Normal Lines to Plane Curves." §5.5 in *Modern Differential Geometry of Curves and Surfaces with Mathematica, 2nd ed.* Boca Raton, FL: CRC Press, pp. 108–111, 1997.

Tangent Vector (Manifold)

Roughly speaking, a tangent vector is an infinitesimal displacement at a specific point on a MANIFOLD. The set of tangent vectors at a point P forms a VECTOR SPACE called the TANGENT SPACE at P, and the collection of tangent spaces on a manifold forms a VECTOR BUNDLE called the TANGENT BUNDLE.

A tangent vector at a point P on a manifold is a tangent vector at P in a COORDINATE CHART. A change in coordinates near P causes an INVERTIBLE LINEAR MAP of the tangent vector's representations in the coordinates. This transformation is given by the JACOBIAN, which must be nonsingular in a change of coordinates. Hence the tangent vectors at P are WELL DEFINED. A VECTOR FIELD is an assignment of a tangent vector for each point. The collection of tangent vectors forms the TANGENT BUNDLE, and a vector field is a SECTION of this bundle.

Tangent vectors are used to do CALCULUS on MANIFOLDS. Since manifolds are locally Euclidean, the usual notions of differentiation and integration make sense in any COORDINATE CHART, and they can be carried over to manifolds. More specifically, a tangent vector is the manifold version of a DIRECTIONAL DERIVATIVE (at a point). An alternative analogy with calculus is the related notion of a VELOCITY VECTOR.

There are at least three different points of view on tangent vectors. Each has its own pluses and minuses. The extrinsic points of view use the vector space structure of EUCLIDEAN SPACE. Thinking of a manifold as a SUBMANIFOLD of Euclidean space, a tangent vector can be thought of as an element in a TANGENT PLANE, or (submanifold) TANGENT SPACE. In a COORDINATE CHART, a tangent vector is a vector in a (chart) TANGENT SPACE, which is just a copy of EUCLIDEAN SPACE.

The problem with the extrinsic points of view is that they depend on a choice of EMBEDDING or COORDINATE CHART. There are a couple of ways to think about a tangent vector intrinsically, as an element of an abstract (intrinsic) TANGENT SPACE. These are more satisfying from an abstract point of view, but sometimes it is necessary to do calculations in coordinate charts.

It is important to distinguish tangent vectors at P from tangent vectors at any other point Q, although they may seem parallel. On a LIE GROUP, there is a notion of parallelism, and there exist nonvanishing vector fields. In general, this is far from being true. On the sphere $\mathbb{S}^2$, for instance, any smooth vector field must vanish somewhere.

A more intrinsic geometric definition of a tangent vector is to take a tangent vector at P to be an EQUIVALENCE CLASS of paths through P which agree to first order. An extrinsic geometric definition, for a submanifold, is to view the tangent vectors as a subspace of the tangent vectors of the ambient space,

Algebraically, a vector field on a manifold is a DERIVATION on the RING of smooth functions. That is, a vector field acts on smooth functions and satisfies the PRODUCT RULE. A vector field X acts on a function by the DIRECTIONAL DERIVATIVE on the function,

$$d_X(f) = X \cdot \nabla f. \tag{1}$$

It is more precise to say that the tangent bundle is the SHEAF of derivations on the sheaf of smooth functions, in which case the tangent vectors at P are in the STALK of the sheaf at P.

In fact, in coordinates $(x_1, \ldots, x_n)$, the notation for the standard basis of tangent vectors at 0 is

$$\frac{\partial}{\partial x_i}, \tag{2}$$

where the derivation $\partial/\partial x_i$ of f is the usual PARTIAL DERIVATIVE

$$\frac{\partial f}{\partial x_i}. \tag{3}$$

Letting the base point vary in the coordinate chart,

$\partial/\partial x_i$ are vector fields, but are only defined in this COORDINATE CHART.

Tangential Angle

For a PLANE CURVE, the tangential angle ϕ is defined by

$$\rho \, d\phi = ds, \tag{1}$$

where s is the ARC LENGTH and ρ is the RADIUS OF CURVATURE. The tangential angle is therefore given by

$$\phi = \int_0^t s'(t)\kappa(t)\, dt, \tag{2}$$

where $\kappa(t)$ is the CURVATURE. For a plane curve $\mathbf{r}(t)$, the tangential angle $\phi(t)$ can also be defined by

$$\frac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} = \begin{bmatrix} \cos[\phi(t)] \\ \sin[\phi(t)] \end{bmatrix}. \tag{3}$$

Gray (1997) calls ϕ the TURNING ANGLE instead of the tangential angle.

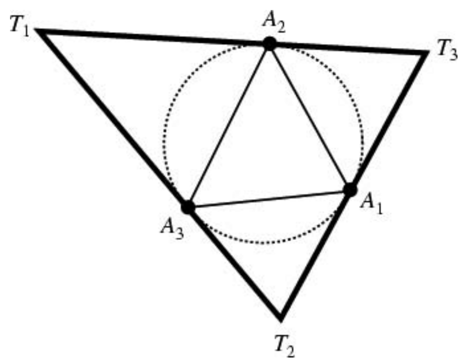
Tangential Tetrahedron

The planes passing through the vertices of a TETRAHEDRON $ABCD$ and tangent to the CIRCUMSPHERE at these points form another tetrahedron called the tangential tetrahedron.



The four lines of intersection of the faces of a tetrahedron with the corresponding faces of its tangential tetrahedron form a hyperbolic group (Altshiller-Court 1979, p. 102).

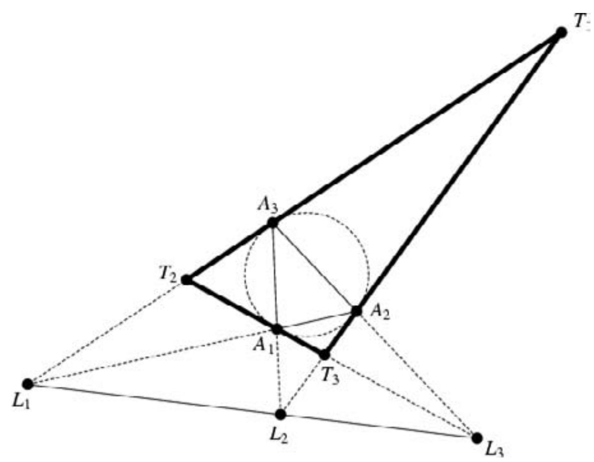
Tangential Triangle



The TRIANGLE $\Delta T_1T_2T_3$ formed by the lines tangent to the CIRCUMCIRCLE of a given TRIANGLE $\Delta A_1A_2A_3$ at its VERTICES. It is the PEDAL TRIANGLE of $\Delta A_1A_2A_3$ with the CIRCUMCENTER as the PEDAL POINT. The TRILINEAR COORDINATES of the VERTICES of the tangential triangle are

$$T_1 = -a : b : c$$

$$T_2 = a : -b : c$$

$$T_3 = a : b : -c.$$

The CONTACT TRIANGLE and tangential triangle are perspective from the GERGONNE POINT.

Given a TRIANGLE $\Delta A_1A_2A_3$ and its tangential triangle $\Delta T_1T_2T_3$, the extensions of the sides of the two triangles intersect in three points L_1, L_2, and L_3, which are collinear (Honsberger 1995).
The CIRCUMCENTER of the tangential triangle has TRIANGLE CENTER FUNCTION

$$\alpha = a\left[b^2 \cos(2B) + c^2 \cos(2C) - a^2 \cos(2, 4)\right]$$

and lies on the EULER LINE (Kimberling 1994)

Tangents Law

LAW OF TANGENTS

Tangent-Sphere Coordinates

A coordinate system $(\mu,\ \nu,\ \psi)$ given by the coordinate transformation

$$x = \frac{\mu \cos \psi}{\mu^2 + \nu^2} \tag{1}$$

$$y = \frac{\mu \sin \psi}{\mu^2 + \nu^2} \tag{2}$$

$$z = \frac{\nu}{\mu^2 + \nu^2} \tag{3}$$

and defined for $\mu > 0$, $\nu \in (-\infty,\ \infty)$, and $\psi \in [0, 2\pi)$. Surfaces of constant μ are given by the TOROIDS

$$x^2 + y^2 + z^2 = \frac{1}{\mu}\sqrt{x^2 + y^2}, \tag{4}$$

surface of constant ν by the spheres tangent to the xy-plane

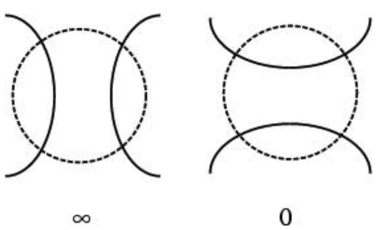
$$x^2 + y^2 + \left(z - \frac{1}{2\nu}\right)^2 = \frac{1}{4\nu^2}, \tag{5}$$

and surfaces of constant ψ by the half-planes

$$\tan \psi = \frac{y}{x}. \tag{6}$$

The metric coefficients are

$$g_{xx} = \frac{1}{(\mu^2 + \nu^2)^2} \tag{7}$$



$$g_{yy} = \frac{1}{(\mu^2 + \nu^2)^2} \tag{8}$$

$$g_{zz} = \frac{\mu^2}{(\mu^2 + \nu^2)^2}. \tag{9}$$

Tangle

A region in a KNOT or LINK projection plane surrounded by a CIRCLE such that the KNOT or LINK crosses the circle exactly four times. Two tangles are equivalent if a sequence of REIDEMEISTER MOVES can be used to transform one into the other while keeping the four string endpoints fixed and not allowing strings to pass outside the CIRCLE.

The simplest tangles are the ∞-tangle and 0-tangle, shown above. A tangle with n left-handed twists is called an n-tangle, and one with n right-handed twists is called a $-n$-tangle. By placing tangles side by side, more complicated tangles can be built up such as $(-2, 3, 2)$, etc. The link created by connecting the ends of the tangles is now described by the sequence of tangle symbols, known as CONWAY'S KNOT NOTATION. If tangles are multiplied by 0 and then added, the resulting tangle symbols are separated by commas. Additional symbols which are used are the period, colon, and asterisk.

Amazingly enough, two tangles described in this NOTATION are equivalent IFF the CONTINUED FRACTIONS OF THE FORM

$$2 + \frac{1}{3 + \frac{1}{-2}}$$

are equal (Burde and Zieschang 1985)! an ALGEBRAIC TANGLE is any tangle obtained by ADDITIONS and MULTIPLICATIONS of rational tangles (Adams 1994). Not all tangles are ALGEBRAIC.

Tanh

HYPERBOLIC TANGENT

Taniyama Conjecture

TANIYAMA-SHIMURA CONJECTURE

Taniyama-Shimura Conjecture

A very general and important conjecture (and now theorem) connecting TOPOLOGY and NUMBER THEORY which arose from several problems proposed by Taniyama in a 1955 international mathematics symposium.

Let E be an ELLIPTIC CURVE whose equation has INTEGER COEFFICIENTS, let N be the so-called CONDUCTOR of E and, for each n, let a_n be the number appearing in the L-function of E. Then, in technical terms, the Taniyama-Shimura conjecture states that there exists a MODULAR FORM of weight two and level N which is an EIGENFORM under the HECKE OPERATORS and has a FOURIER SERIES $\Sigma\, a_n q^n$.

In effect, the conjecture says that every rational ELLIPTIC CURVE is a MODULAR FORM in disguise. Or, more formally, the conjecture suggests that, for every ELLIPTIC CURVE $y^2 = Ax^3 + Bx^2 + Cx + D$ over the RATIONALS, there exist nonconstant MODULAR FUNCTIONS $f(z)$ and $g(z)$ of the same level N such that

$$[f(z)]^2 = A[g(z)]^2 + Cg(z) + D.$$

Equivalently, for every ELLIPTIC CURVE, there is a MODULAR FORM with the same DIRICHLET L-SERIES.

In 1985, starting with a fictitious solution to FERMAT'S LAST THEOREM (the FREY CURVE), G. Frey showed that he could create an unusual ELLIPTIC CURVE which appeared not to be modular. If the curve were not modular, then this would show that if FERMAT'S LAST THEOREM were false, then the Taniyama-Shimura conjecture would also be false. Furthermore, if the Taniyama-Shimura conjecture were true, then so would be FERMAT'S LAST THEOREM!

However, Frey did not actually prove that his curve was not modular. The conjecture that Frey's curve *was not* modular came to be called the "EPSILON CONJECTURE," and was quickly proved by Ribet (RIBET'S THEOREM) in 1986, establishing a very close link between two mathematical structures (the Taniyama-Shimura conjecture and FERMAT'S LAST THEOREM) which appeared previously to be completely unrelated.

As of the early 1990s, most mathematicians believed that the Taniyama-Shimura conjecture was not accessible to proof. However, A. Wiles was not one of these. He attempted to establish the correspondence between the set of ELLIPTIC CURVES and the set of modular elliptic curves by showing that the number of each was the same. Wiles accomplished this by "counting" Galois representations and comparing them with the number of MODULAR FORMS. In 1993, after a monumental seven-year effort, Wiles (almost) proved the Taniyama-Shimura conjecture for special classes of curves called SEMISTABLE ELLIPTIC CURVES (which correspond to elliptic curves with SQUAREFREE CONDUCTORS; Knapp 1999).

Wiles had tried to use horizontal Iwasawa theory to create a so-called CLASS NUMBER FORMULA, but was initially unsuccessful and therefore used instead an extension of a result of Flach based on ideas from Kolyvagin. However, there was a problem with this extension which was discovered during review of Wiles' manuscript in September 1993. Former student Richard Taylor came to Princeton in early 1994 to help Wiles patch up this error. After additional effort, Wiles discovered the reason that the Flach/Kolyvagin approach was failing, and also discovered that it was precisely what had prevented Iwasawa theory from working.

With this additional insight, Wiles was able to successfully complete the erroneous portion of the

proof using Iwasawa theory, proving the SEMISTABLE case of the Taniyama-Shimura conjecture (Taylor and Wiles 1995, Wiles 1995) and, at the same time, establishing FERMAT'S LAST THEOREM as a true theorem.

The existence of a proof of the *full* Taniyama-Shimura conjecture was announced at a conference by Kenneth Ribet on June, 21 1999 (Knapp 1999), and reported on National Public Radio's Weekend Edition on July 31, 1999. The proof was completed by Christophe Breuil, Brian Conrad, Fred Diamond, and Richard Taylor, building on the earlier work of Wiles and Taylor (Mackenzie 1999, Morgan 1999). The best previous published result held for all CONDUCTORS except those divisible by 27 (Conrad *et al.* 1999; Knapp 1999). The general Breuil *et al.* proof for *all* elliptic curves removed this restriction, in the process relying on Wiles' proof for rational ELLIPTIC CURVES.

Tarry Point

The point T at which the lines through the VERTICES of a TRIANGLE PERPENDICULAR to the corresponding sides of the first BROCARD TRIANGLE, are CONCURRENT. The Tarry point lies on the CIRCUMCIRCLE opposite the STEINER POINT S. It has TRIANGLE CENTER FUNCTION

$$\alpha = \frac{bc}{b^4 + c^4 - a^2b^2 - a^2c^2} = \sec(A + \omega),$$

where ω is the BROCARD ANGLE. The SIMSON LINE of the Tarry point is PERPENDICULAR to the line OK, when O is the CIRCUMCENTER and K is the SYMMEDIAN POINT (Lachlan 1893; Johnson 1929; Honsberger 1995, p. 121). The Tarry point of the first BROCARD TRIANGLE of a TRIANGLE ΔABC is the CIRCUMCENTER of ΔABC (Honsberger 1995, pp. 120-121).

Tarry-Escott Problem

PROUHET-TARRY-ESCOTT PROBLEM

Tarski's Recursive Definition of Satisfaction

SATISFACTION

Tarski's Theorem

Portions of this entry contributed by ADAM STRZEBONSKI

Tarski's theorem says that the first-order theory of reals with +, *, =, and > allows QUANTIFIER ELIMINATION. This property is stronger than DECIDABILITY. For example, the first-order theory of reals with +, *, and = is decidable, but does not allow QUANTIFIER ELIMINATION.

Tarski's theorem means that a QUANTIFIED SYSTEM of real algebraic equations and inequalities is a SEMIALGEBRAIC SET (Strzebonski 2000).

Although Tarski proved that QUANTIFIER ELIMINATION was possible, his method was totally impractical (Davenport and Heintz 1988). A much more efficient procedure for implementing QUANTIFIER ELIMINATION is called CYLINDRICAL ALGEBRAIC DECOMPOSITION. It was developed by Collins (1975) and is implemented in *Mathematica* 4.0 as `CylindricalAlgebraicDecomposition`.

Tau Conjecture

Also known as RAMANUJAN'S HYPOTHESIS. Ramanujan proposed that

$$\tau(n) \sim \mathcal{O}\left(n^{11/2+\epsilon}\right),$$

where $\tau(n)$ is the TAU FUNCTION. This was proven by Deligne (1974) in the course of proving the more general PETERSSON CONJECTURE. Deligne was awarded the FIELDS MEDAL for his proof.

Tau Function

A function $\tau(n)$ related to the DIVISOR FUNCTION $\sigma_k(n)$, also sometimes called RAMANUJAN'S TAU FUNCTION. It is defined via the FOURIER SERIES of the MODULAR DISCRIMINANT $\Delta(\tau)$ for $\tau \in H$, where H is the UPPER HALF-PLANE, by

$$\Delta(\tau) = (2\pi)^{12} \sum_{n=1}^{\infty} \tau(n) e^{2\pi i n \tau} \tag{1}$$

(Apostol 1997, p. 20). The tau function is also given by the CAUCHY PRODUCT

$$\tau(n) = 8000\{(\sigma_3 \circ \sigma_3) \circ \sigma_3\}(n) - 147(\sigma_5 \circ \sigma_5)(n), \tag{2}$$

$$= \tfrac{65}{756}\,\sigma_{11}(n) + \tfrac{691}{756}\,\sigma_5(n) - \tfrac{691}{3} \sum_{k=1}^{n-1} \sigma_5(k)\sigma_5(n-k), \tag{3}$$

where $\sigma_k(n)$ is the DIVISOR FUNCTION (Apostol 1997, pp. 24 and 140). The tau function has GENERATING FUNCTION

$$\sum_{n=1}^{\infty} \tau(n) x^n = x \prod_{n=1}^{\infty} (1-x^n)^{24}, \tag{4}$$

and the first few values are 1, -24, 252, -1472, 4830, ... (Sloane's A000594). The tau function is given by the *Mathematica* command `RamanujanTau[n]` in the *Mathematica* add-on package `NumberTheory`Ramanujan`` (which can be loaded with the command `<<NumberTheory``).

Lehmer conjectured that $\tau(n) \neq 0$ for all n and verified this fact for $n < 214928639999$ (Apostol 1997, p. 22).

$\tau(n)$ is also given by

$$g(-x) = \sum_{n=1}^{\infty} (-1)^n \tau(n) x^n \quad (5)$$

$$g(x^2) = \sum_{n=1}^{\infty} \tau\left(\tfrac{1}{2} n\right) x^n \quad (6)$$

$$\sum_{n=1}^{\infty} \tau(n) x^n = x\left(1 - 3x + 5x^3 - 7x^6 + \ldots\right)^8. \quad (7)$$

Ewell (1999) gave the beautiful formulas

$$\tau(4n+2) = -3 \sum_{k=1}^{2n+1} 2^{3b(2k)} \sigma_3(\mathrm{Od}(2k)) \times \sum_{j=0}^{4n-2k+2} (-1)^j r_8(4n+2-2k-j) r_8(j) \quad (8)$$

$$\sum_{k=1}^{n} 2^{3b(2k)} \sigma_3(\mathrm{Od}2k)) \times \sum_{j=0}^{2n+1-2k} (-1)^j r_8(2n+1-2k-j) r_8(j) = 0 \quad (9)$$

$$\tau(4m) = -2^{11}\tau(m) - 3 \sum_{k=1}^{2m} 2^{3b(2k)} \sigma_3(\mathrm{Od}2k)) \times \sum_{j=0}^{4m-2k} (-1)^j r_8(4m-2k-j) r_8(j) \quad (10)$$

$$\tau(2n+1) = \sum_{k=1}^{2n+1} 2^{3[b(2k)-1]} \sigma_3(\mathrm{Od}2k)) \times \sum_{j=0}^{2n+2-2k} (-1)^j r_8(3n+2-2k-j) r_8(j), \quad (11)$$

where $b(n)$ is the exponent of the exact power of 2 dividing n, $\mathrm{Od}(n)$ is the ODD PART of n, $\sigma_k(n)$ is the DIVISOR FUNCTION of n, and $r_k(n)$ is the SUM OF SQUARES FUNCTION.

For PRIME p,

$$\tau\left(p^{n+1}\right) = \tau(p)\tau(p^n) - p^{11}\tau\left(p^{n-1}\right) \quad (12)$$

for $n \geq 1$, and

$$\tau(p^\alpha n) = \tau(p)\tau\left(p^{\alpha-1} n\right) - p^{11}\tau\left(p^{\alpha-2} n\right) \quad (13)$$

for $\alpha \geq 2$ and $(n, p) = 1$ (Mordell 1917; Apostol 1997, p. 92).

In ORE'S CONJECTURE, the tau function appears as the number of DIVISORS of n. Ramanujan conjectured and Mordell (1917) proved that if $(n, n') = 1$, then

$$\tau(nn') = \tau(n)\tau(n'). \quad (14)$$

More generally,

$$\tau(n)\tau(n') = \sum_{d\,|\,(n,\,n')} d^{11} \tau\left(\frac{nn'}{d^2}\right), \quad (15)$$

which reduces to the first form if $(n, n') = 1$ (Mordell 1917; Apostol 1997, p. 93). Ramanujan conjectured and Watson proved that $\tau(n)$ is divisible by 691 for almost all n, specifically

$$\tau(n) \equiv \sigma_{11}(n) \pmod{691}, \quad (16)$$

where $\sigma_k(n)$ is the DIVISOR FUNCTION (Wilton 1930, Apostol 1997, pp. 93 and 140) and 691 is the NUMERATOR of the BERNOULLI NUMBER B_{12}.

Ramanujan (1920) showed that

$$\tau(2n) \equiv 0 \pmod 2 \quad (17)$$

$$\tau(3n) \equiv 0 \pmod 3 \quad (18)$$

$$\tau(5n) \equiv 0 \pmod 5 \quad (19)$$

(Darling 1921; Wilton 1930),

$$\tau(7n+m) \equiv 0 \pmod 7 \quad (20)$$

for $m = 0$ or one the quadratic non-residues of 7, i.e., 3, 5, 6, and

$$\tau(23n+m) \equiv 0 \pmod{23} \quad (21)$$

for $m = 0$ or one the quadratic non-residues of 23, i.e., 5, 7, 10, 11, 14, 15, 17, 19, 20, 21, 22 (Mordell 1922; Wilton 1930). Ewell (1999) showed that

$$\tau(4n) \equiv \tau(n) \pmod 3. \quad (22)$$

$\tau(n)$ is almost always divisible by $2^5 \cdot 3^3 \cdot 5^2 \cdot 7^2 \cdot 23 \cdot 691$ according to Ramanujan. In fact, Serre has shown that $\tau(n)$ is almost always divisible by any integer (Andrews *et al.* 1988).

Ramanujan also studied the DIRICHLET L-SERIES

$$f(x) \equiv \sum_{n=1}^{\infty} \tau(n) n^{-s}, \quad (23)$$

which has properties analogous to the RIEMANN ZETA FUNCTION. It satisfies

$$\frac{f(s)\Gamma(s)}{(2\pi)^s} = \frac{f(12-s)}{(2\pi)^{12-s}}. \quad (24)$$

It also has the Euler product representation

$$\sum_{n=1}^{\infty} \frac{\tau(n)}{n^s} = \prod_p \frac{1}{1 - \tau(p)p^{-s} + p^{11-2s}} \quad (25)$$

for $\sigma = \Re[s] > 7$ (since $\tau(n) = \mathcal{O}(n^6)$) (Apostol 1997, p. 137). Ramanujan's TAU-DIRICHLET SERIES conjecture alleges that all nontrivial zeros of $f(s)$ lie on the line $\Re[s] = 6$. f can be split up into

$$f(6+it) = z(t)e^{-i\theta(t)}, \quad (26)$$

where

$$z(t)=\Gamma(6+it)f(6+it)(2\pi)^{-it}$$
$$\times\sqrt{\frac{\sinh(\pi t)}{\pi t(1+t^2)(4+t^2)(9+t^2)(16+t^2)(25+t^2)}} \quad (27)$$

$$\theta(t)=-\tfrac{1}{2}\,i\,\ln\left[\frac{\Gamma(6+it)}{\Gamma(6-it)}\right]-t\ln(2\pi). \quad (28)$$

The functions $f(s)$, $\theta(t)$, and $z(t)$ are returned by the *Mathematica* commands RamanujanTauDirichletSeries[s] in the *Mathematica* add-on package NumberTheory'Ramanujan' (which can be loaded with the command << NumberTheory'), RamanujanTauTheta[t] in the *Mathematica* add-on package NumberTheory'Ramanujan' (which can be loaded with the command << NumberTheory'), and RamanujanTauZ[t] in the *Mathematica* add-on package NumberTheory'Ramanujan' (which can be loaded with the command << NumberTheory'), respectively.

The SUMMATORY tau function is given by

$$T(n)=\sum_{n\leq x}\tau(n). \quad (29)$$

Here, the prime indicates that when x is an INTEGER, the last term $\tau(x)$ should be replaced by $\frac{1}{2}\tau(x)$.

Ramanujan's tau theta function $Z(t)$ is a REAL function for REAL t and is analogous to the RIEMANN-SIEGEL FUNCTION Z. The number of zeros in the critical strip from $t=0$ to T is given by

$$N(t)=\frac{\Theta(T)+\Im\{\ln[\tau_{DS}(6+iT)]\}}{\pi}, \quad (30)$$

where Θ is the RIEMANN THETA FUNCTION and τ_{DS} is the TAU-DIRICHLET SERIES, defined by

$$\tau_{DS}(s)\equiv\sum_{n=1}^{\infty}\frac{\tau(n)}{n^s}. \quad (31)$$

Ramanujan conjectured that the nontrivial zeros of the function are all real.

Ramanujan's τ_z function is defined by

$$\tau_z(t)=\frac{\Gamma(6+it)(2\pi)^{-it}}{\tau_{DS}(6+it)\sqrt{\frac{\sinh(\pi t)}{\pi t\prod_{k=1}^{5}k^2+t^2}}}, \quad (32)$$

where $\tau_{DS}(z)$ is the TAU-DIRICHLET SERIES.

Tauberian Theorem

A Tauberian theorem is a theorem which deduces the convergence of an INFINITE SERIES on the basis of the properties of the function it defines and any kind of auxiliary HYPOTHESIS which prevents the general term of the series from converging to zero too slowly. Hardy (1999, p. 46) states that "a 'Tauberian' theorem may be defined as a corrected form of the false converse of an 'ABELIAN THEOREM'."

Wiener's Tauberian theorem states that if $f\in L^1(\mathbb{R})$, then the translates of f spans a dense subspace IFF the FOURIER TRANSFORM is nonzero everywhere. This theorem is analogous with the theorem that if $f\in$

$L^1(\mathbb{Z})$ (for a BANACH ALGEBRA with a unit), then f spans the whole space if and only if the GELFAND TRANSFORM is nonzero everywhere.

Tautochrone Problem

The problem of finding the curve down which a bead placed anywhere will fall to the bottom in the same amount of time. The solution is a CYCLOID, a fact first discovered and published by Huygens in *Horologium oscillatorium* (1673). This property was also alluded to in the following passage from *Moby Dick*: "[The try-pot] is also a place for profound mathematical meditation. It was in the left-hand try-pot of the *Pequod*, with the soapstone diligently circling round me, that I was first indirectly struck by the remarkable fact, that in geometry all bodies gliding along a cycloid, my soapstone, for example, will descend from any point in precisely the same time" (Melville 1851).

Huygens also constructed the first pendulum clock with a device to ensure that the pendulum was isochronous by forcing the pendulum to swing in an arc of a CYCLOID. This is accomplished by placing two evolutes of inverted cycloid arcs on each side of the pendulum's point of suspension against which the pendulum is constrained to move (Wells 1991, p. 47; Gray 1997, p. 123). Unfortunately, friction along the arcs causes a greater error than that corrected by the cycloidal path (Gardner 1984).

The PARAMETRIC EQUATIONS of the CYCLOID are

$$x = a(\theta - \sin\theta) \tag{1}$$

$$y = a(1 - \cos\theta). \tag{2}$$

To see that the CYCLOID satisfies the tautochrone property, consider the derivatives

$$x' = a(1 - \cos\theta) \tag{3}$$

$$y' = a\sin\theta, \tag{4}$$

and

$$x'^2 + y'^2 = a^2\left[(1 - 2\cos\theta + \cos^2\theta) + \sin^2\theta\right]$$

$$= 2a^2(1 - \cos\theta). \tag{5}$$

Now

$$\tfrac{1}{2}mv^2 = mgy \tag{6}$$

$$v = \frac{ds}{dt} = \sqrt{2gy} \tag{7}$$

$$dt = \frac{ds}{\sqrt{2gy}} = \frac{\sqrt{dx^2 + dy^2}}{\sqrt{2gy}}$$

$$= \frac{a\sqrt{2(1-\cos\theta)}\,d\theta}{\sqrt{2ga(1-\cos\theta)}} = \sqrt{\frac{a}{g}}\,d\theta, \tag{8}$$

so the time required to travel from the top of the CYCLOID to the bottom is

$$T = \int_0^{\pi} dt = \sqrt{\frac{a}{g}}\,\pi. \tag{9}$$

However, from an intermediate point θ_0,

$$v = \frac{ds}{dt} = \sqrt{2g(y - y_0)}, \tag{10}$$

so

$$T = \int_{\theta_0}^{\pi} \sqrt{\frac{2a^2(1-\cos\theta)}{2ag(\cos\theta_0 - \cos\theta)}}\,d\theta$$

$$= \sqrt{\frac{a}{g}} \int_{\theta_0}^{\pi} \sqrt{\frac{1 - \cos\theta}{\cos\theta_0 - \cos\theta}}\, d\theta. \tag{11}$$

To integrate, rearrange this equation using the HALF-ANGLE FORMULAS

$$\sin\left(\tfrac{1}{2}x\right) = \sqrt{\frac{1 - \cos x}{2}} \tag{12}$$

$$\cos\left(\tfrac{1}{2}x\right) = \sqrt{\frac{1 + \cos x}{2}} \tag{13}$$

with the latter rewritten in the form

$$\cos\theta = 2\cos^2\left(\tfrac{1}{2}\theta\right) - 1 \tag{14}$$

to obtain

$$T = \sqrt{\frac{a}{g}} \int_{\theta_0}^{\pi} \frac{\sin\left(\frac{1}{2}\theta\right)\, d\theta}{\sqrt{\cos^2\left(\frac{1}{2}\theta_0\right) - \cos^2\left(\frac{1}{2}\theta\right)}}. \tag{15}$$

Now transform variables to

$$u = \frac{\cos\left(\frac{1}{2}\theta\right)}{\cos\left(\frac{1}{2}\theta_0\right)} \tag{16}$$

$$du = -\frac{\sin\left(\frac{1}{2}\theta\right)\, d\theta}{2\cos\left(\frac{1}{2}\theta_0\right)}, \tag{17}$$

so

$$T = -2\sqrt{\frac{a}{g}} \int_1^0 \frac{du}{\sqrt{1 - u^2}} = 2\sqrt{\frac{a}{g}}\left[\sin^{-1} u\right]_0^1 = \pi\sqrt{\frac{a}{g}}, \tag{18}$$

and the amount of time is the same from any point.

Tautology

A logical statement in which the conclusion is equivalent to the premise. If p is a tautology, it is written $\models p$. A SENTENCE whose TRUTH TABLE contains only 'T' is called a tautology. The following SENTENCES are examples of tautologies:

$$A \wedge B \equiv\, !(!A \vee !B) \tag{1}$$

$$A \vee B \equiv\, !A \Rightarrow B \tag{2}$$

$$A \wedge B \equiv\, !(A \Rightarrow !B) \tag{3}$$

(Mendelson 1997, p. 26), where $\wedge$ denotes AND, $\equiv$ denotes "is EQUIVALENT to," ! denotes NOT, $\vee$ denotes OR, and $\Rightarrow$ denotes implies.

Taxicab Number

The nth taxicab number $\mathrm{Ta}(n)$ is the smallest number representable in n ways as a sum of POSITIVE CUBES. The numbers derive their name from the HARDY-RAMANUJAN NUMBER

$$\begin{aligned} \mathrm{Ta}(2) &= 1729 \\ &= 1^3 + 12^3 \\ &= 9^3 + 10^3, \end{aligned} \tag{1}$$

which is associated with a story told about Ramanujan by G. H. Hardy (Hofstadter 1989, Kanigel 1991, Snow 1993).

However, this property was also known as early as 1657 by F. de Bessy (Berndt and Bhargava 1993, Guy 1994). Leech (1957) found

$$\begin{aligned} \mathrm{Ta}(3) &= 87539319 \\ &= 167^3 + 436^3 \\ &= 228^3 + 423^3 \\ &= 255^3 + 414^3. \end{aligned} \tag{2}$$

Rosenstiel *et al.* (1991) recently found

$$\begin{aligned} \mathrm{Ta}(4) &= 6963472309248 \\ &= 2421^3 + 19083^3 \\ &= 5436^3 + 18948^3 \\ &= 10200^3 + 18072^3 \\ &= 13322^3 + 16630^3. \end{aligned} \quad (3)$$

D. Wilson found

$$\begin{aligned} \mathrm{Ta}(5) &= 48988659276962496 \\ &= 38787^3 + 365757^3 \\ &= 107839^3 + 362753^3 \\ &= 205292^3 + 342952^3 \\ &= 221424^3 + 336588^3 \\ &= 231518^3 + 331954^3. \end{aligned} \quad (4)$$

The first few taxicab numbers are therefore 2, 1729, 87539319, 6963472309248, ... (Sloane's A011541).

Hardy and Wright (Theorem 412, 1979) show that the number of such sums can be made arbitrarily large but, updating Guy (1994) with Wilson's result, the least example is not known for six or more equal sums.

Sloane defines a slightly different type of taxicab numbers, namely numbers which are sums of two cubes in two or more ways, the first few of which are 1729, 4104, 13832, 20683, 32832, 39312, 40033, 46683, 64232, ... (Sloane's A001235).

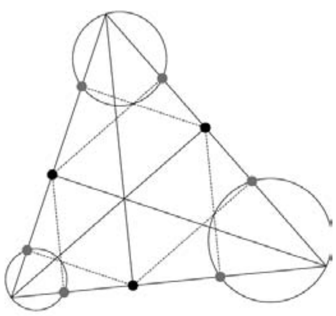
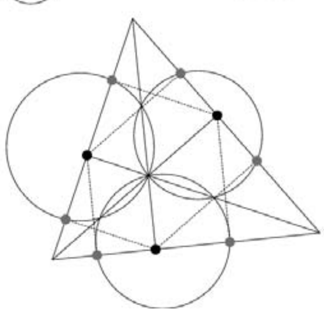
Johnson, R. A. *Modern Geometry: An Elementary Treatise on the Geometry of the Triangle and the Circle.* Boston, MA: Houghton Mifflin, p. 277, 1929.



Taylor Circle



From the feet H_A, H_B, and H_C of each ALTITUDE of a TRIANGLE, draw lines PERPENDICULAR to the adjacent sides. Then the CIRCUMCIRCLE of the triangle formed by the PERPENDICULAR FEET is called the Taylor circle, and its center is called the TAYLOR CENTER. The Taylor circle is a TUCKER CIRCLE.

There are a number of remarkable properties satisfied by the figure obtained in the construction of the Taylor circle. These facts are probably well-known, but I have not seen them explicitly described elsewhere.

1. The feet of the perpendiculars from a given altitude foot are concyclic with the opposite vertex.
2. The two feet of the perpendiculars which are closest to a given vertex are concyclic with the feet of the altitudes on the corresponding sides.
3. The two feet of the perpendiculars which are closest to a give vertex are concyclic with that vertex and with the intersection of the perpendiculars.
4. The three circles through the ORTHOCENTER and the feet of the perpendiculars on a given side intersect pairwise along the altitudes.

Taylor Expansion

TAYLOR SERIES

Taylor Polynomial

TAYLOR SERIES

Taylor Series

A Taylor series is a SERIES EXPANSION of a FUNCTION about a point. A 1-D Taylor series is an expansion of a REAL FUNCTION $f(x)$ about a point $x = x_0$ (sometimes written instead $x = a$). If $x = 0$, the expansion is known as a MACLAURIN SERIES.

To derive the Taylor series of a function $f(x)$, note that the integral of the $(n+1)$st DERIVATIVE $f^{(n+1)}$ of $f(x)$ from the point x_0 to an arbitrary point x is given by

$$\int_{x_0}^{x} f^{(n+1)}(x)\, dx = \left[f^{(n)}(x)\right]_{x_0}^{x} = f^{(n)}(x) - f^{(n)}(x_0), \tag{1}$$

where $f^{(n)}(x_0)$ is the nth derivative of $f(x)$ evaluated at x_0, and is therefore simply a constant. Now integrate a second time to obtain

$$\begin{aligned}\int_{x_0}^{x}\left[\int_{x_0}^{x} f^{(n+1)}(x)\, dx\right] dx &= \int_{x_0}^{x}\left[f^{(n)}(x) - f^{(n)}(x_0)\right] dx \\ &= \left[f^{(n-1)}(x)\right]_{x_0}^{x} - (x - x_0) f^{(n)}(x_0) \\ &= f^{(n-1)}(x) - f^{(n-1)}(x_0) - (x - x_0) f^{(n)}(x_0),\end{aligned} \tag{2}$$

where $f^{(k)}(x_0)$ is again a constant. Integrating a third time,

$$\int\int\int_{x_0}^{x} f^{(n+1)}(x)(dx)^3 = f^{(n-2)}(x) - f^{(n-2)}(x_0)$$

$$-(x-x_0)f^{(n-1)}(x_0) - \frac{(x-x_0)^2}{2!} f^{(n)}(x_0), \qquad (3)$$

and continuing up to $n+1$ integrations then gives

$$\underbrace{\int \cdots \int_{x_0}^{x}}_{n+1} f^{(n+1)}(x)(dx)^{n+1}$$

$$= f(x) - f(x_0) - (x-x_0)f'(x_0) - \frac{(x-x_0)^2}{2!} f''(x_0)$$

$$- \ldots - \frac{(x-x_0)^n}{n!} f^{(n)}(x_0). \qquad (4)$$

Rearranging then gives the one-dimensional Taylor series

$$f(x) = f(x_0) + (x-x_0)f'(x_0) + \frac{(x-x_0)^2}{2!} f''(x_0) + \ldots$$

$$+ \frac{(x-x_0)^n}{n!} f^{(n)}(x_0) + R_n, \qquad (5)$$

$$= \sum_{k=0}^{n} \frac{(x-x_0)^k f^{(k)}(x_0)}{k!} + R_n. \qquad (6)$$

Here, R_n is a remainder term known as the LAGRANGE REMAINDER, which is given by

$$R_n = \underbrace{\int \cdots \int_{x_0}^{x}}_{n+1} f^{(n+1)}(x)(dx)^{n+1}. \qquad (7)$$

Rewriting the MULTIPLE INTEGRAL then gives

$$R_n = \int_{x_0}^{x} f^{(n+1)}(t) \frac{(x-t)^n}{n!}\, dt. \qquad (8)$$

Now, from the MEAN-VALUE THEOREM for a function $g(x)$, it must be true that

$$\int_{x_0}^{x} g(x)\, dx = (x-x_0)g(x^*) \qquad (9)$$

for some $x^* \in [x_0, x]$. Therefore, integrating $n+1$ times gives the result

$$R_n = \frac{(x+x_0)^{n+1}}{(n+1)!} f^{(n+1)}(x^*), \qquad (10)$$

so the maximum error after n terms of the Taylor series is the maximum value of (10) running through all $x^* \in [x_0, x]$. Note that the Lagrange remainder R_n is also sometimes taken to refer to the remainder when terms up to the $(n-1)$st power are taken in the Taylor series (Whittaker and Watson 1990, pp. 95–96).

An alternative form of the 1-D Taylor series may be obtained by letting

$$x - x_0 \equiv \Delta x \qquad (11)$$

so that

$$x \equiv x_0 + \Delta x. \qquad (12)$$

Substitute this result into (5) to give

$$f(x_0 + \Delta x) = f(x_0) + \Delta x f'(x_0) + \tfrac{1}{2!}(\Delta x)^2 f''(x_0) + \ldots. \qquad (13)$$

A Taylor series of a REAL FUNCTION in two variables $f(x, y)$ is given by

$$f(x+\Delta x, y+\Delta y) = f(x, y) + [f_x(x, y)\Delta x + f_y(x, y)\Delta y]$$

$$+\tfrac{1}{2!}[(\Delta x)^2 f_{xx}(x, y) + 2\Delta x \Delta y f_{xy}(x, y) + (\Delta y)^2 f_{yy}(x, y)]$$

$$+\tfrac{1}{3!}[(\Delta x)^3 f_{xxx}(x, y) + 3(\Delta x)^2 \Delta y f_{xxy}(x, y)$$

$$+3\Delta x(\Delta y)^2 f_{xyy}(x, y) + (\Delta y)^3 f_{yyy}(x, y)] + \ldots. \qquad (14)$$

This can be further generalized for a REAL FUNCTION in n variables,

$$f(x_1, \ldots, x_n)$$

$$= \sum_{j=0}^{\infty} \left\{ \frac{1}{j!} \left[\sum_{k=1}^{n} (x'_k - a_k) \frac{\partial}{\partial x'_k} \right]^j f(x'_1, \ldots, x'_n) \right\}_{x'_1=a_1, \ldots, x'_n=a_n}. \qquad (15)$$

Rewriting,

$$f(x_1 + a_1, \ldots, x_n + a_n)$$

$$= \sum_{j=0}^{\infty} \left\{ \frac{1}{j!} \left[\sum_{k=1}^{n} a_k \frac{\partial}{\partial x'_k} \right]^j f(x'_1, \ldots, x'_n) \right\}_{x'_1=a_1, \ldots, x'_n=a_n}.$$

Taking $n = 2$ in (15) gives

$$f(x_1, x_2) = \sum_{j=0}^{\infty} \left\{ \frac{1}{j!} \left[(x'_1 - a_1) \frac{\partial}{\partial x'_1} \right.\right.$$

$$\left.\left. + (x'_2 - a_2) \frac{\partial}{\partial x'_2} \right]^j f(x'_1, x'_2) \right\}_{x'_1=x1,\ x'_2=x_2}$$

$$= f(a_1, a_2) + \left[(x_1 - a_1) \frac{\partial f}{\partial x_1} + (x_2 - a_2) \frac{\partial f}{\partial x_2} \right]$$

$$+\tfrac{1}{2!} \left[(x_1 - a_1)^2 \frac{\partial^2 f}{\partial x_1^2} + 2(x_1 - a_1)(x_2 - a_2) \frac{\partial^2 f}{\partial x_1 \partial x_2} \right.$$

$$+(x_2-a_2)^2\frac{\partial^2 f}{\partial x_2^2}\bigg] + \ldots. \tag{17}$$

Taking $n=3$ in (16) gives

$$f(x_1+a_1,\ x_2+x_2+a_2,\ x_3+a_3)$$
$$=\sum_{j=0}^{\infty}\left\{\frac{1}{j!}\left(a_1\frac{\partial}{\partial x_1'}+a_2\frac{\partial}{\partial x_2'}+a_3\frac{\partial}{\partial x_3'}\right)^j\right.$$
$$\left.\times f(x_1',\ x_2',\ x_3')\right\}_{x_1'=x_1,\ x_2'=x_2,\ x_3'=x_3}, \tag{18}$$

or, in VECTOR form

$$f(\mathbf{r}+\mathbf{a})=\sum_{j=0}^{\infty}\left[\frac{1}{j!}(\mathbf{a}\cdot\nabla_{\mathbf{r}'})^j f(\mathbf{r}')\right]_{\mathbf{r}'=\mathbf{r}} \tag{19}$$

The zeroth- and first-order terms are

$$f(\mathbf{r}) \tag{20}$$

and

$$(\mathbf{a}\cdot\nabla_{\mathbf{r}'})f(\mathbf{r}')\mid_{\mathbf{r}'=\mathbf{r}}, \tag{21}$$

respectively. The second-order term is

$$\tfrac{1}{2}(\mathbf{a}\cdot\nabla_{\mathbf{r}'})(\mathbf{a}\cdot\nabla_{\mathbf{r}'})f(\mathbf{r}')|_{\mathbf{r}'=\mathbf{r}}=\tfrac{1}{2}\,\mathbf{a}\cdot\nabla_{\mathbf{r}'}[\mathbf{a}\cdot(\nabla f(\mathbf{r}'))]_{\mathbf{r}'=\mathbf{r}}$$
$$=\tfrac{1}{2}\,\mathbf{a}\cdot[\mathbf{a}\cdot\nabla_{\mathbf{r}'}(\nabla_{\mathbf{r}}f(\mathbf{r}'))]|_{\mathbf{r}'=\mathbf{r}}, \tag{22}$$

so the first few terms of the expansion are

$$f(\mathbf{r}+\mathbf{a})=f(\mathbf{r})+(\mathbf{a}\cdot\nabla_{\mathbf{r}'})f(\mathbf{r}')\mid_{\mathbf{r}'=\mathbf{r}}+\tfrac{1}{2}\,\mathbf{a}$$
$$\cdot[\mathbf{a}\cdot\nabla_{\mathbf{r}'}(\nabla\mathbf{r}'f(\mathbf{r}'))]|_{\mathbf{r}'=\mathbf{r}}. \tag{23}$$

Taylor series can also be defined for functions of a COMPLEX variable. By the CAUCHY INTEGRAL FORMULA,

$$f(z)=\frac{1}{2\pi i}\int_C\frac{f(z')\,dz}{z'-z}=\frac{1}{2\pi i}\int_C\frac{f(z')\,dz'}{(z'-z_0)-(z-z_0)}$$
$$=\frac{1}{2\pi i}\int_C\frac{f(z')\,dz'}{(z'-z_0)\left(1-\dfrac{z-z_0}{z'-z0}\right)}. \tag{24}$$

In the interior of C,

$$\frac{|z-z_0|}{|z'-z_0|}<1 \tag{25}$$

so, using

$$\frac{1}{1-t}=\sum_{n=0}^{\infty}t^n, \tag{26}$$

it follows that

$$f(z)=\frac{1}{2\pi i}\int_C\sum_{n=0}^{\infty}\frac{(z-z_0)^n f(z')\,dz'}{(z'-z_0)^{n+1}}$$
$$=\frac{1}{2\pi i}\sum_{n=0}^{\infty}(z-z_0)^n\int_C\frac{f(z')\,dz}{(z'-z_0)^{n+1}}. \tag{27}$$

Using the CAUCHY INTEGRAL FORMULA for derivatives,

$$f(z)=\sum_{n=0}^{\infty}(z-z_0)^n\frac{f^{(n)}(z_0)}{n!}. \tag{28}$$

Taylor-Greene-Chirikov Map

STANDARD MAP

Taylor's Condition

For a given POSITIVE INTEGER n, does there exist a WEIGHTED TREE with n VERTICES whose paths have weights 1, 2, ..., $\binom{n}{2}$, where $\binom{n}{2}$ is a BINOMIAL

COEFFICIENT? Taylor showed that no such TREE can exist unless it is a PERFECT SQUARE or a PERFECT SQUARE plus 2. No such TREES are known except $n = 2$, 3, 4, and 6.

Taylor's Theorem

The theorem that a function may be represented by a TAYLOR SERIES,

$$f(x) = f(0) + xf'(0) + \frac{x^2}{2!} f''(0) + \ldots + \frac{x^{n-1}}{(n-1)!} f^{(n-1)}(0) + \int_0^x \frac{(x-u)^{n-1}}{(n-1)!} f^{(n)}(u)\, du.$$

Taylor's theorem without the remainder was first devised by Taylor in 1712 and published in 1915, but it was not until almost a century later than Lagrange and Cauchy derived approximations of the remainder term after a finite number of terms (Moritz 1937). These forms are now called the LAGRANGE REMAINDER and CAUCHY REMAINDER.

Most modern proofs are based on Cox (1851), which is more elementary than that of Cauchy and Lagrange (Moritz 1923), and which Pringsheim (1900) referred to as "leaving hardly anything to wish for in terms of simplicity and strength" (Moritz 1923).

Teeko

A game described by Scarne which is played on a 5×5 board by two players who alternate placing, one at a time, their four counters each, after which the counters are moved around (including diagonally). Four counters in a row or square wins (Beeler *et al.* 1972). In general, there are sixteen forms of the game, all of which were solved completely by Guy Steele in 1998 with the following results: standard teeko (44 winning configurations) is a draw, and advanced teeko (58 winning configurations) is a first-player win.

Here is a more complete summary of the results.

Variant	Winner
standard	draw
alternate	draw
one-move alternate	draw
two-move alternate	draw
three-move alternate	draw
one-move standard	draw

two-move standard	draw
three-move standard	draw
standard, 58 positions	first-player win (13 turns)
alternate, 58 positions	draw
one-move alternate, 58 positions	draw
two-move alternate, 58 positions	draw
three-move alternate, 58 positions	draw
one-move standard, 58 positions	first-player win (25 turns)
two-move standard, 58 positions	draw
three-move standard, 58 positions	draw

Teixeira's Theorem

An extended form of Bürmann's theorem. Let $f(z)$ be a function of z analytic in a ring-shaped region A, bounded by another curve C and an inner curve c. Let $\theta(z)$ be a function analytic on and inside C having only one zero a (which is simple) within the contour. Further let x be a given point within A. Finally, let

$$|\theta(x)|<|\theta(z)| \tag{1}$$

for all points z of C, and

$$|\theta(x)| > |\theta(z)| \tag{2}$$

for all points z of c. Then

$$f(x)=\sum_{n=0}^{\infty} A_n[\theta(x)]^n+\sum_{n=1}^{\infty} \frac{B_n}{[\theta(x)]^n}, \tag{3}$$

where

$$A_n=\frac{1}{2\pi i}\int_C \frac{f(z)\theta'(z)\,dz}{[\theta(z)]^{n+1}} \tag{4}$$

$$B_n=\frac{1}{2\pi i}\int_c f(z)[\theta(z)]^{n-1}\theta'(z)\,dz \tag{5}$$

(Whittaker and Watson 1990, pp. 131–132).

Gossiping

Telescoping Sum

A sum in which subsequent terms cancel each other, leaving only initial and final terms. For example,

$$S = \sum_{i=1}^{n+1} (a_i - a_{i+1})$$
$$= (a_1 - a_2) + (a_2 - a_3) + \ldots + (a_{n-2} - a_{n-1})$$
$$+ (a_{n-1} - a_n)$$
$$= (a_1 - a_n)$$

is a telescoping sum.

See also Zeilberger's Algorithm

Temperature

The "temperature" of a curve Γ is defined as

$$T \equiv \frac{1}{\ln\left(\frac{2l}{2l - h}\right)},$$

where l is the length of Γ and h is the length of the perimeter of the convex hull. The temperature of a curve is 0 only if the curve is a straight line, and increases as the curve becomes more "wiggly."

Tensor

An nth-rank tensor in m-space is a mathematical object in m-dimensional space that has n indices and m^n components and obeys certain transformation rules. Each index of a tensor ranges over the number of dimensions of space. However, the dimension of the space is largely irrelevant in most tensor equations (with the notable exception of the contracted Kronecker delta).

The notation for a tensor is similar to that of a matrix (i.e., $A = (a_{ij})$), except that a tensor $a_{i,\,j,\,k,\,\ldots}$ may have an arbitrary number of indices. In addition, a tensor with rank $r+s$ may be of mixed type (r, s), with r so-called "contravariant" indices and s "covariant" indices, denoted $a^{j_1,\,\ldots,\,j_s}_{i_1,\,\ldots,\,i_r}$. Technically, a matrix is a tensor of type $(1,\ 1)$ and would be written a_i^j in tensor notation.

In *Mathematica*, a tensor of rank n is represented using nested lists of depth n, and tensors can be generated using the command `Array`[a, {i, j, ...}]. Similarly, the dimensions of a tensor can be found using `Dimensions`[t], and the rank can be found using `Rank`[t]. Taking for example

```
t = Array[a, {1, 2, 2, 3}]
```

gives the rank-4 tensor of dimensions {1, 2, 2, 3},

```
{{{{a[1, 1, 1, 1], a[1, 1, 1, 2], a[1, 1, 1, 3]},
```

```
   {a[1,1,2,1],a[1,1,2,2],a[1,1,2,3]}},
  {{a[1,2,1,1],a[1,2,1,2],a[1,2,1,3]},
   {a[1,2,2,1], a[1,2,2,2],a[1,2,2,3]}}},
 {{{a[2,1,1,1],a[2,1,1,2],a[2,1,1,3]},
   {a[2,1,2,1],a[2,1,2,2],a[2,1,2,3]}},
  {{a[2,2,1,1],a[2,2,1,2],a[2,2,1,3]},
   {a[2,2,2,1],a[2,2,2,2],a[2,2,2,3]}}}}.
```

In n-dimensional space, each element a_{ijkl} would then represent an n-vector.

A TENSOR SPACE of type (r, s) can be described as a TENSOR PRODUCT between r copies of VECTOR FIELDS and s copies of the dual vector fields, i.e., ONE-FORMS. For example,

$$T^{(3,\ 1)} = TM \otimes TM \otimes TM \otimes T^*M \tag{1}$$

is the VECTOR BUNDLE of $(3,\ 1)$-tensors on a MANIFOLD M, where TM is the TANGENT BUNDLE of M and T^*M is its dual. Tensors of type (r, s) form a VECTOR SPACE. This description generalized to any tensor type, and an INVERTIBLE LINEAR MAP $J : V \to W$ induces a map $\tilde{J} : V \otimes V^* \to W \otimes W^*$, where V^* is the DUAL VECTOR SPACE and J the JACOBIAN, defined by

$$\tilde{J}(v_1 \otimes v_2^*) = \left(Jv_1 \otimes \left(J^T\right)^{-1} v_2^*\right), \tag{2}$$

where J^T is the PULLBACK MAP of a form is defined using the transpose of the JACOBIAN. This definition can be extended similarly to other TENSOR PRODUCTS of V and V^*. When there is a change of COORDINATES, then tensors transform similarly, with J the JACOBIAN of the linear transformation.

Zeroth-rank tensors are called SCALARS, and first-rank tensors are called VECTORS. In tensor notation, a vector $\mathbf{v}$ would be written v_i, where $i = 1, \ldots, m$. Tensor notation can provide a very concise way of writing vector and more general identities. For example, in tensor notation, the DOT PRODUCT $\mathbf{u} \cdot \mathbf{v}$ is simply written

$$\mathbf{u} \cdot \mathbf{v} = u_i v^i, \tag{3}$$

where repeated indices are summed over (EINSTEIN SUMMATION). Similarly, the CROSS PRODUCT can be concisely written as

$$\mathbf{u} \times \mathbf{v} = \epsilon_{ijk} u^j v^k, \tag{4}$$

where ϵ_{ijk} is the PERMUTATION TENSOR.

CONTRAVARIANT second-rank tensors are objects which transform as

$$A'^{ij} = \frac{\partial x'_i}{\partial x_k} \frac{\partial x'_j}{\partial x'_l} A^{kl}. \tag{5}$$

COVARIANT second-rank tensors are objects which transform as

$$C'_{ij} = \frac{\partial x_k}{\partial x'_i} \frac{\partial x_l}{\partial x'_j} C_{kl}. \tag{6}$$

MIXED second-rank tensors are objects which transform as

$$B'^{i}_{j} = \frac{\partial x'_i}{\partial x_k} \frac{\partial x_l}{\partial x'_j} B^k_l. \tag{7}$$

If two tensors A and B have the same rank and the same COVARIANT and CONTRAVARIANT indices, then the can be added in the obvious way,

$$A^{ij} + B^{ij} = C^{ij} \tag{8}$$

$$A_{ij} + B_{ij} = C_{ij} \tag{9}$$

$$A^i_j + B^i_j = C^i_j. \tag{10}$$

The indices of a tensor can be raised or lowered (INDEX RAISING and INDEX LOWERING, respectively) by multiplication by a so-called METRIC TENSOR, e.g.,

$$g^{ij} A_j = A^i \tag{11}$$

$$g_{ij} A^j = A_i \tag{12}$$

(Arfken 1985, p. 159). The generalization of the DOT PRODUCT applied to tensors is called CONTRACTION, and consists of setting two unlike indices equal to each other and then summing using the EINSTEIN SUMMATION convention. Various types of derivatives can be taken of tensors, the most common being the COMMA DERIVATIVE and COVARIANT DERIVATIVE.

If the components of any tensor of any RANK vanish in one particular coordinate system, they vanish in all coordinate systems. A transformation of the variables of a tensor changes the tensor into another whose components are linear HOMOGENEOUS FUNCTIONS of the components of the original tensor.

Tensor Calculus

The set of rules for manipulating and calculating with TENSORS.

Tensor Density

A quantity which transforms like a TENSOR except for a scalar factor of a JACOBIAN.

Tensor Direct Product

Abstractly, the tensor direct product is the same as the TENSOR PRODUCT. However, it reflects an approach toward calculation using coordinates, and indices in particular. The notion of tensor product is more algebraic, intrinsic, and abstract. For instance, up to ISOMORPHISM, the tensor product is commutative because $V\otimes W\cong W\otimes V$. Note this does not mean that the tensor product is symmetric.

For two first-RANK TENSORS (i.e., VECTORS), the tensor direct product is defined as

$$a_i'b'^j\equiv\frac{\partial x_k}{\partial x_i'}\,a_k\,\frac{\partial x_j'}{\partial x_l}\,b^l=\frac{\partial x_k}{\partial x_i'}\,\frac{\partial x_j'}{\partial x_l}\left(a_kb^l\right),\qquad(1)$$

which is a second-RANK TENSOR. The CONTRACTION of a direct product of first-RANK TENSORS is the SCALAR

$$\operatorname{contr}\left(a_i'b'^j\right)=a_i'b'^i=a_kb^k.\qquad(2)$$

For second-RANK TENSORS,

$$A_j^iB^{kl}=C_j^{ikl}\qquad(3)$$

$$C_j^{ikl'}=\frac{\partial x_i'}{\partial x_m}\,\frac{\partial x_n}{\partial x_j'}\,\frac{\partial x_k'}{\partial x_p}\,\frac{\partial x_l'}{\partial x_q}\,C_n^{mpq}.\qquad(4)$$

In general, the direct product of two TENSORS is a TENSOR of RANK equal to the sum of the two initial RANKS. The direct product is ASSOCIATIVE, but not COMMUTATIVE.

The tensor direct product of two tensors a and b can be implemented in *Mathematica* as

```
TensorDirectProduct[a_List,     b_List]     :=
Outer[Times, a, b]
```

See also DIRECT PRODUCT, MATRIX DIRECT PRODUCT, TENSOR PRODUCT (VECTOR SPACE)

References

Arfken, G. "Contraction, Direct Product." §3.2 in *Mathematical Methods for Physicists, 3rd ed.* Orlando, FL: Academic Press, pp. 124–126, 1985.

Tensor Dual

DUAL TENSOR

Tensor Product

TENSOR DIRECT PRODUCT, TENSOR PRODUCT (MODULE), TENSOR PRODUCT (VECTOR SPACE)

Tensor Product (Module)

The tensor product between MODULES A and B is a more general notion than the TENSOR PRODUCT BETWEEN VECTOR SPACES. In this case, we replace "scalars" by a RING R. The familiar formulas hold, but now α is any element of R,

$$(a_1+a_2)\otimes b=a_1\otimes b+a_2\otimes b\qquad(1)$$

$$a\otimes(b_1+b_2)=a\otimes b_1+a\otimes b_2\qquad(2)$$

$$\alpha(a\otimes b)=(\alpha a)\otimes b=a\otimes(\alpha b).\qquad(3)$$

This generalizes the definition of a tensor product for vector spaces since a VECTOR SPACE is a module over the scalar field. Also, VECTOR BUNDLES can be considered as PROJECTIVE MODULES over the ring of functions, and REPRESENTATIONS of a group G can be thought of as modules over CG. The generalization covers those kinds of tensor products as well.

There are some interesting possibilities for the tensor product of modules that don't occur in the case of vector spaces. It is possible for $A\otimes_R B$ to be identically zero. For example, the tensor product of $\mathbb{Z}_2$ and $\mathbb{Z}_3$ as modules over the integers, $\mathbb{Z}_2\otimes_{\mathbb{Z}}\mathbb{Z}_3$, has no nonzero elements. It is enough to see that $a\otimes b=0$. Notice that $1=3-2$. Then

$$(1)a\otimes b=(3-2)a\otimes b=(-2a)\otimes b+a\otimes(3b)=0+0$$
$$=0,\qquad(4)$$

since $-2a = -a - a = 0$ in $\mathbb{Z}_2$ and $3b = b + b + b = 0$ in $\mathbb{Z}_3$. In general, it is easier to show that elements are zero than to show they are not zero.

Another interesting property of tensor products is that if $f : A \to B$ is ONTO, then so is the induced map $g : A \otimes C \to B \otimes C$ for any other module C. But if $f : A \to B$ is injective, then $g : A \otimes C \to B \otimes C$ may not be injective.

For example, $f : \mathbb{Z}_2 \to \mathbb{Z}_4$, with $f(1) = 2$ is injective, but $g : \mathbb{Z}_2 \otimes_{\mathbb{Z}} \mathbb{Z}_2 \to \mathbb{Z}_4 \otimes_{\mathbb{Z}} \mathbb{Z}_2$, with $g(1 \otimes 1) = 2 \otimes 1$, is not injective. In $\mathbb{Z}_4 \otimes_{\mathbb{Z}} \mathbb{Z}_2$, we have $2 \otimes 1 = 1 \otimes 2 = 1 \otimes 0 = 0.$.

There is an algebraic description of this failure of injectivity, called the TOR module.

Another way to think of the tensor product is in terms of its UNIVERSAL PROPERTY: Any BILINEAR MAP from $A \times B :\to C$ factors through the natural bilinear map $A \times B \to A \otimes B.$.

See also MODULE, MODULE DIRECT SUM, PROJECTIVE MODULE, REPRESENTATION, TENSOR PRODUCT (MODULE), TENSOR PRODUCT (REPRESENTATION), TENSOR PRODUCT (VECTOR SPACE), TOR, UNIVERSAL PROPERTY, VECTOR BUNDLE, VECTOR SPACE

Tensor Product (Representation)

The TENSOR PRODUCT $V \otimes W$ of two REPRESENTATIONS of a GROUP G is also a REPRESENTATION of G. An element g of G acts on a basis element $v \otimes w$ by

$$g(v \otimes w) = gv \otimes gw.$$

If G is a FINITE GROUP and V is a FAITHFUL representation, then any representation is contained in $\otimes^n V$ for some n. If V_1 is a representation of G_1 and V_2 is a representation of G_2, then $V_1 \otimes V_2$ is a representation of $G_1 \times G_2$, called the EXTERNAL TENSOR PRODUCT. The regular tensor product is a special case, with the diagonal embedding of G in $G \times G$.

See also EXTERNAL TENSOR PRODUCT, GROUP, IRREDUCIBLE REPRESENTATION, REPRESENTATION, TENSOR PRODUCT (VECTOR SPACE), VECTOR SPACE

Tensor Product (Vector Space)

The tensor product of two VECTOR SPACES V and W, denoted $V \otimes W$ and also called the TENSOR DIRECT PRODUCT, is a way of creating a new VECTOR SPACE analogous to multiplication of integers. For instance,

$$\mathbb{R}^n \otimes \mathbb{R}^k \cong \mathbb{R}^{nk}. \tag{1}$$

In particular,

$$\mathbb{R} \otimes \mathbb{R}^n \cong \mathbb{R}^n. \tag{2}$$

Also, the tensor product obeys a distributive law with the DIRECT SUM operation:

$$U \otimes (V \oplus W) \cong (U \otimes V) \oplus (U \otimes W). \tag{3}$$

The analogy with an algebra is the motivation behind K-THEORY. The tensor product of two tensors a and b can be implemented in *Mathematica* as

```
TensorProduct[a_List, b_List] := Outer[List,
a, b]
```

Algebraically, the vector space $V \otimes W$ is SPANNED by elements OF THE FORM $v \otimes w$, and the following rules are satisfied, for any scalar α. The definition is the same no matter which scalar FIELD is used.

$$(v_1 + v_2) \otimes w = v_1 \otimes w + v_2 \otimes w \tag{4}$$

$$v \otimes (w_1 + w_2) = v \otimes w_1 + v \otimes w_2 \tag{5}$$

$$\alpha(v \otimes w) = (\alpha v) \otimes w = v \otimes (\alpha w) \tag{6}$$

One basic consequence of these formulas is that

$$0 \otimes w = v \otimes 0 = 0. \tag{7}$$

A VECTOR BASIS v_i of V and w_j of W gives a basis for $V \otimes W$, namely $v_i \otimes w_j$, for all pairs (i, j). An arbitrary element of $V \otimes W$ can be written uniquely as $\Sigma\, a_{i,\, j} v_i \otimes w_j$, where $a_{i,\, j}$ are scalars. If V is n dimensional and W is k dimensional, then $V \otimes W$ has dimension nk.

Using tensor products, one can define SYMMETRIC TENSORS, ANTISYMMETRIC TENSORS, as well as the EXTERIOR ALGEBRA. Moreover, the tensor product is generalized to the TENSOR PRODUCT OF VECTOR BUNDLES. In particular, tensor products of the TANGENT BUNDLE and its DUAL BUNDLE are studied in RIEMANNIAN GEOMETRY and physics. Sections of these bundles are often called TENSORS. In addition, it is possible to take the TENSOR PRODUCT OF REPRESENTATIONS to get another representation.

All of these versions of tensor product can be understood as TENSOR PRODUCTS OF MODULES. The trick is to find the right way to think of these spaces as MODULES.

See also ANTISYMMETRIC TENSOR, EXTERIOR ALGEBRA, FIELD, K-THEORY, MODULE, SYMMETRIC TENSOR, TENSOR, TENSOR DIRECT PRODUCT, TENSOR PRODUCT (MODULE), TENSOR PRODUCT (REPRESENTATION), VECTOR SPACE

Tensor Space

Let E be a linear space over a FIELD K. Then the TENSOR PRODUCT $\otimes_{\lambda=1}^{k} E$ is called a tensor space of degree k. More specifically, a tensor space of type (r, s) can be described as a TENSOR PRODUCT between r copies of VECTOR FIELDS and s copies of the dual vector fields, i.e., ONE-FORMS. For example,

$$T^{(3,\, 1)} = TM \otimes TM \otimes TM \otimes T^*M \tag{1}$$

is the VECTOR BUNDLE of $(3,\ 1)$ tensors on a MANIFOLD M. Tensors of type (r, s) form a VECTOR SPACE.

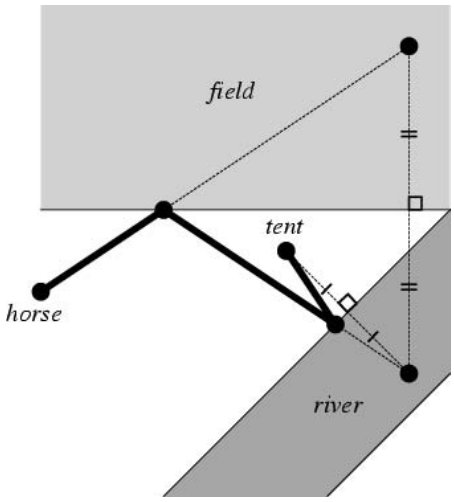
Tent Map



A piecewise linear, 1-D MAP on the interval [0, 1] exhibiting CHAOTIC dynamics and given by

$$x_{n+1} = \mu\left(1 - 2\left|x_n - \tfrac{1}{2}\right|\right).$$

The case $\mu = 1$ is equivalent to the LOGISTIC EQUATION WITH $R = 4$. The NATURAL INVARIANT of the tent map is $\rho = 1$.

See also 2X MOD 1 MAP, LOGISTIC EQUATION, LOGISTIC EQUATION: $R = 4$

Tent Problem

Consider a horse rider who wishes to feed his horse at a field, gather water from a river, and then return to his tent, all in the smallest overall distance possible. The path he should take is obtained by reflecting the tent across the near river bank, then reflecting this point about the field boundary, as illustrated above.

Terminal

SINK (DIRECTED GRAPH)

Ternary

The BASE 3 method of counting in which only the digits 0, 1, and 2 are used. Ternary numbers arise in a number of problems in mathematics, including some problems of WEIGHING. According to Knuth (1981), "no substantial application of balanced ternary notation has been made" (balanced ternary uses digits -1, 0, and 1 instead of 0, 1, and 2). The following table gives the ternary equivalents of the first few decimal numbers.

1	1	11	102	21	210
2	2	12	110	22	211
3	10	13	111	23	212
4	11	14	112	24	220
5	12	15	120	25	221
6	20	16	121	26	222
7	21	17	122	27	1000
8	22	18	200	28	1001
9	100	19	201	29	1002
10	101	20	202	30	1010

Ternary digits have the following MULTIPLICATION TABLE.

×	0	1	2
0	0	0	0
1	0	1	2
2	0	2	11

Every EVEN NUMBER represented in ternary has an EVEN NUMBER (possibly 0) of 1s. This is true since a number is congruent mod $(B-1)$ to the sum of its base-B digits. In the case $B = 3$, there is only one digit (1) which is not a multiple of $B-1$, so all we have to do is "cast out twos" and count the number of 1s in the base-3 representation.

Erdos and Graham (1980) conjectured that no POWER of 2, 2^n, is a SUM of distinct powers of 3 for $n > 8$. This is equivalent to the requirement that the ternary expansion of 2^n always contains a 2. This has been verified by Vardi (1991) up to $n = 2 \cdot 3^{30}$. N. J. A. Sloane has conjectured that any POWER of 2 has a 0 in its ternary expansion (Vardi 1991, p. 28).

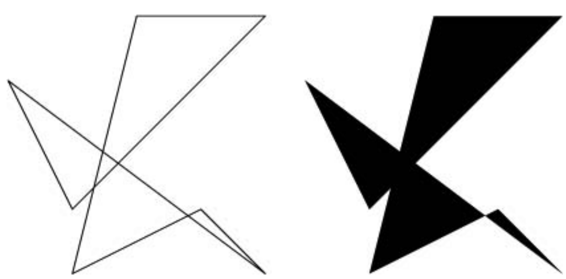
Ternary Goldbach Conjecture



GOLDBACH CONJECTURE

Ternary Tree

See also BINARY TREE, COMPLETE TERNARY TREE

Tessellation

A regular TILING of POLYGONS (in 2-D), POLYHEDRA (3-D), or POLYTOPES (n-D) is called a tessellation. Tessellations can be specified using a SCHLÄFLI SYMBOL.

The breaking up of self-intersecting polygons into simple polygons (illustrated above) is also called tessellation (Woo *et al.* 1999).

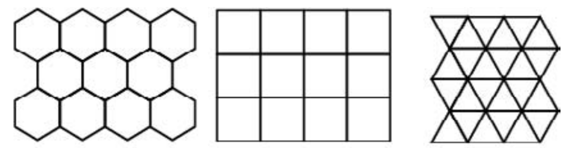
Consider a 2-D tessellation with q regular p-gons at each VERTEX. In the PLANE,

$$\left(1-\frac{2}{p}\right)\pi=\frac{2\pi}{q} \tag{1}$$

$$\frac{1}{p}+\frac{1}{q}=\frac{1}{2}, \tag{2}$$

so

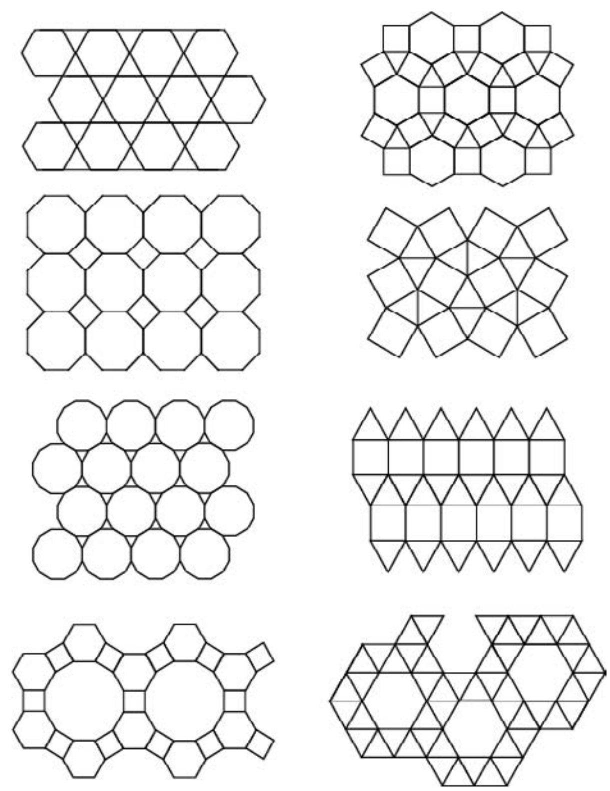
$$(p-2q)(q-2)=4 \tag{3}$$



(Ball and Coxeter 1987), and the only factorizations are

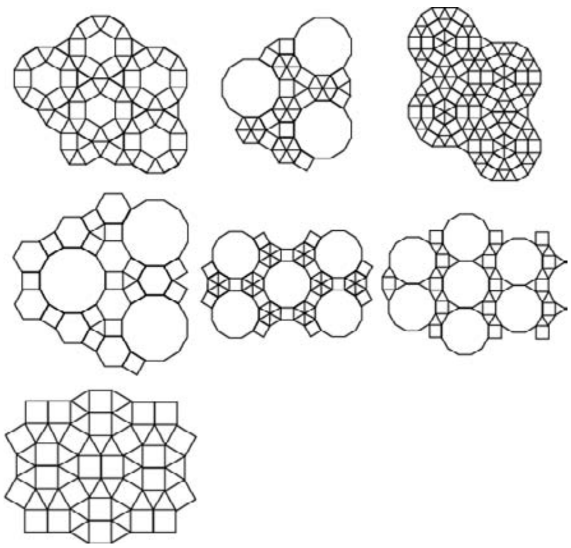
$$4=4\cdot 1=(6-2)(3-2)\Rightarrow\{6,\ 3\} \tag{4}$$

$$=2\cdot 2=(4-2)(4-2)\Rightarrow\{4,\ 4\} \tag{5}$$



$$=1\cdot 4=(3-2)(6-2)\Rightarrow\{3,\ 6\}. \tag{6}$$

Therefore, there are only three regular tessellations (composed of the HEXAGON, SQUARE, and TRIANGLE), illustrated as follows (Ghyka 1977, p. 76; Williams 1979, p. 36; Wells 1991, p. 213)



{6, 3} {4, 4} {3, 6}

There do not exist any regular STAR POLYGON tessellations in the PLANE. Regular tessellations of the SPHERE by SPHERICAL TRIANGLES are called TRIANGULAR SYMMETRY GROUPS.

Regular tessellations of the plane by *two or more* convex regular POLYGONS such that the same POLYGONS in the same order surround each VERTEX are called semiregular tessellations, or sometimes Archimedean tessellations. In the plane, there are eight such tessellations, illustrated below (Ghyka 1977, pp. 76–78; Williams 1979, pp. 37–41; Steinhaus 1983, pp. 78–82; Wells 1991, pp. 226–227). Williams (1979, pp. 37–41) also illustrates the DUAL TESSELLATIONS of the semiregular tessellations. The DUAL TESSELLATION of the tessellation of squares and

equilateral triangles is called the CAIRO TESSELLATION (Williams 1979, p. 38; Wells 1991, p. 23).

There are 14 polymorph, or demiregular, tessellations which are orderly compositions of the three regular and eight semiregular tessellations (Critchlow 1970, pp. 62–67; Ghyka 1977, pp. 78–80; Williams 1979, p. 43; Steinhaus 1983, pp. 79 and 81–82).

In 3-D, a POLYHEDRON which is capable of tessellating space is called a SPACE-FILLING POLYHEDRON. Examples include the CUBE, RHOMBIC DODECAHEDRON, and TRUNCATED OCTAHEDRON. There is also a 16-sided space-filler and a convex POLYHEDRON known as the SCHMITT-CONWAY BIPRISM which fills space only aperiodically.

A tessellation of n-D polytopes is called a HONEYCOMB.

Tesseract

The HYPERCUBE in $\mathbb{R}^4$, also called the 8-cell, is known as a tesseract. It has the SCHLÄFLI SYMBOL $\{4,\ 3,\ 3\}$, and VERTICES $(\pm 1,\ \pm 1,\ \pm 1,\ \pm 1)$. The above figures show two visualizations of the tesseract. The figure on the left is a projection of the tesseract in 3-space (Gardner 1977), and the figure on the right is the GRAPH of the tesseract symmetrically projected into

the PLANE (Coxeter 1973). A tesseract has 16 VERTICES, 32 EDGES, 24 SQUARES, and 8 CUBES.

Tesseral Harmonic

A SPHERICAL HARMONIC OF THE FORM $\begin{smallmatrix}\cos\\ \sin\end{smallmatrix}(m\phi)P_l^{m(\cos\theta)}$. These harmonics are so named because the curves on which they vanish are $l-m$ parallels of latitude and $2m$ meridians, which divide the surface of a sphere into quadrangles whose angles are right angles (Whittaker and Watson 1990, p. 392).

Resolving $P_l(\cos\theta)$ into factors linear in $\cos^2\theta$, multiplied by $\cos\theta$ when l is ODD, then replacing $\cos\theta$ by z/r allows the tesseral harmonics to be expressed as products of factors linear in x^2, y^2, and z^2 multiplied by one of $1, x, y, z, yz, zx, xy$, and xyz (Whittaker and Watson 1990, p. 536).

Tetrahedral Number

A FIGURATE NUMBER Te_n OF THE FORM

$$Te_n = \sum_{i=1}^{n} T_n = \tfrac{1}{6} n(n+1)(n+2) = \binom{n+2}{3}, \qquad (1)$$

where T_n is the nth TRIANGULAR NUMBER and $\binom{n}{m}$ is a BINOMIAL COEFFICIENT. These numbers correspond to placing discrete points in the configuration of a TETRAHEDRON (triangular base pyramid). Tetrahedral numbers are PYRAMIDAL NUMBERS with $r=3$, and are the sum of consecutive TRIANGULAR NUMBERS. The first few are 1, 4, 10, 20, 35, 56, 84, 120, ... (Sloane's A000292). The GENERATING FUNCTION of the tetrahedral numbers is

$$\frac{x}{(x-1)^4} = x + 4x^2 + 10x^3 + 20x^4 + \ldots. \qquad (2)$$

Tetrahedral numbers are EVEN, except for every fourth tetrahedral number, which is ODD (Conway and Guy 1996).

The only numbers which are simultaneously SQUARE and TETRAHEDRAL are $Te_1 = 1$, $Te_2 = 4$, and $Te_{48} = 19600$ (giving $S_1 = 1$, $S_2 = 4$, and $S_{140} = 19600$), as proved by Meyl (1878; cited in Dickson 1952, p. 25).

Numbers which are simultaneously TRIANGULAR and TETRAHEDRAL satisfy the BINOMIAL COEFFICIENT equation

$$T_n = \binom{n+1}{2} = \binom{m+2}{3} = Te_m, \qquad (3)$$

the only solutions of which are

$$Te_1 = T_1 = 1 \qquad (4)$$

$$Te_3 = T_4 = 10 \qquad (5)$$

$$Te_8 = T_{15} = 120 \qquad (6)$$

$$Te_{20} = T_{55} = 1540 \qquad (7)$$

$$Te_{34} = T_{119} = 7140 \qquad (8)$$

(Sloane's A027568; Avanesov 1966/1967; Mordell 1969, p. 258; Guy 1994, p. 147).

Beukers (1988) has studied the problem of finding numbers which are simultaneously tetrahedral and PYRAMIDAL via INTEGER points on an ELLIPTIC CURVE, and finds that the only solution is the trivial $Te_1 = P_1 = 1$.

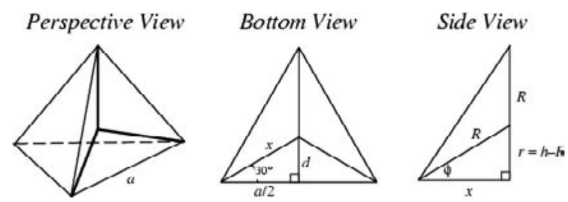
Tetrahedron

The regular tetrahedron, often simply called "the" tetrahedron, is the PLATONIC SOLID P_1 with four VERTICES, six EDGES, and four equivalent EQUILATERAL TRIANGULAR faces, $4\{3\}$. It is also UNIFORM POLYHEDRON U_1 and Wenninger model W_1. It is described by the SCHLÄFLI SYMBOL $\{3, 3\}$ and the WYTHOFF SYMBOL is $3 \mid 2\ 3$.



It is the prototype of the TETRAHEDRAL GROUP T_d. The connectivity of the vertices is given by the TETRAHEDRAL GRAPH, equivalent to the CIRCULANT GRAPH $Ci_{1,\,2,\,3}(4)$ and the COMPLETE GRAPH K_4.

The tetrahedron is its own DUAL POLYHEDRON, and therefore the centers of the faces of a tetrahedron form another tetrahedron (Steinhaus 1983, p. 201). The tetrahedron is the only simple POLYHEDRON with no DIAGONALS, and it cannot be STELLATED. If a regular tetrahedron is cut by six planes, each passing through an edge and bisecting the opposite edge, it is sliced into 24 pieces (Gardner 1984, pp. 190 and 192; and Langman 1951).

Alexander Graham Bell was a proponent of use of the tetrahedron in framework structures, including kites (Bell 1903; Lesage 1956, Gardner 1984, pp. 184–185). The opposite edges of a tetrahedron are perpendicular, and so can form a universal coupling if hinged appropriately. Eight regular tetrahedra can be placed in a ring which rotates freely, and the number can be reduced to six for squashed irregular tetrahedra (Wells 1975, 1991)

Let a tetrahedron be length a on a side. The VERTICES are located at $(x, 0, 0)$, $(-d, \pm a/2, 0)$, and $(0, 0, h)$. From the figure,

$$x = \frac{\frac{a}{2}}{\cos\left(\frac{\pi}{6}\right)} = \tfrac{1}{3}\sqrt{3}a. \tag{1}$$

d is then

$$d = \sqrt{x^2 - \left(\tfrac{1}{2}a\right)^2} = \tfrac{1}{6}\sqrt{3}a. \tag{2}$$

This gives the AREA of the base as

$$A = \tfrac{1}{2}a(R + x) = \tfrac{1}{4}\sqrt{3}a^2. \tag{3}$$

The height is

$$h = \sqrt{a^2 - x^2} = \tfrac{1}{3}\sqrt{6}a. \tag{4}$$

The CIRCUMRADIUS R is found from

$$x^2 + (h - R)^2 = R^2 \tag{5}$$

$$x^2 + h^2 - 2hR + R^2 = R^2. \tag{6}$$

Solving gives

$$R = \frac{x^2 + h^2}{2h} = \tfrac{1}{4}\sqrt{6}a \approx 0.61237a. \tag{7}$$

The INRADIUS r is

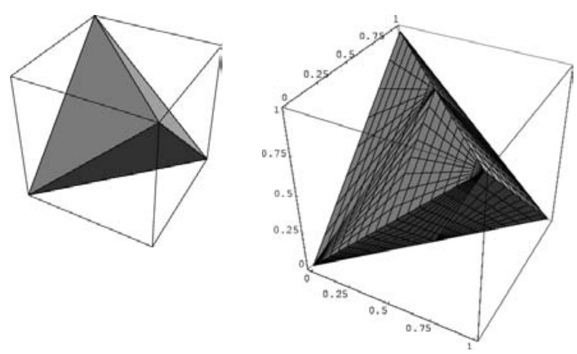
$$r \equiv h - R = \tfrac{1}{12}\sqrt{6}a \approx 0.20412a, \tag{8}$$

which is also

$$r = \tfrac{1}{4} h = \tfrac{1}{3} R. \qquad (9)$$

The ANGLE between the bottom plane and center is then given by

$$\phi = \tan^{-1}\left(\frac{r}{x}\right) = \tan^{-1}\left(\tfrac{1}{4}\sqrt{2}\right). \qquad (10)$$



Given a tetrahedron of edge length a situated with vertical apex and with the origin of coordinate system at the CENTROID of the vertices, the four VERTICES are located at $(x,\ 0,\ -r)$, $(-d,\ \pm a/2,\ -r)$, $(0,\ 0,\ R)$, with, as shown above

$$x = \tfrac{1}{3}\sqrt{3}a \qquad (11)$$

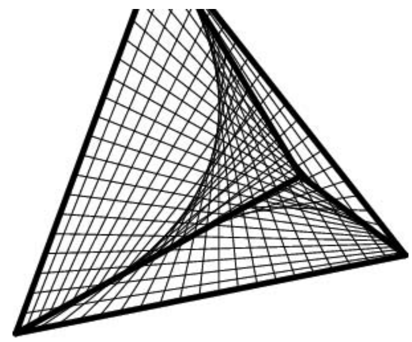
$$r = \tfrac{1}{12}\sqrt{6}a \qquad (12)$$

$$R = \tfrac{1}{4}\sqrt{6}a \qquad (13)$$

$$d = \tfrac{1}{6}\sqrt{3}a. \qquad (14)$$

The vertices of a tetrahedron of side length $\sqrt{2}$ can also be given by a particularly simple form when the vertices are taken as corners of a cube (Gardner 1984, pp. 192–194). One such tetrahedron for a cube of side length 1 gives the tetrahedron of side length $\sqrt{2}$ having vertices (0, 0, 0), (0, 1, 1), (1, 0, 1), (1, 1, 0), and satisfies the inequalities

$$x + y + z \le 2 \qquad (15)$$



$$x - y - z \le 0 \qquad (16)$$

$$-x + y - z \le 0 \qquad (17)$$

$$-x - y + z \le 0. \qquad (18)$$

The following table gives polyhedra which can be constructed by CUMULATION of a tetrahedron by pyramids of given heights h.

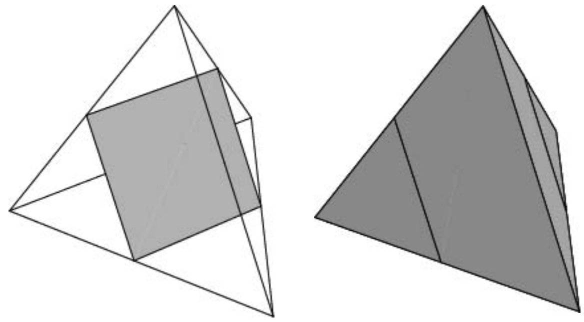
h	$(r+h)/h$	Result
$\frac{1}{15}\sqrt{6}$	$\frac{7}{5}$	TRIAKIS TETRAHEDRON
$\frac{1}{6}\sqrt{6}$	2	CUBE
$\frac{1}{3}\sqrt{6}$	3	9-faced star DELTAHEDRON

Connecting opposite pairs of edges with equally spaced lines gives a configuration like that shown above which divides the tetrahedron into eight regions: four open and four closed (Steinhaus 1983, p. 246).

The MIDRADIUS of the tetrahedron is

$$\rho = \sqrt{r^2 + d^2} = \sqrt{\tfrac{1}{8}}\, a = \tfrac{1}{4}\sqrt{2}a$$
$$\approx 0.35355a. \qquad (19)$$

Plugging in for the VERTICES gives



$$\left(a\sqrt{3},\ 0,\ 0\right), \left(-\tfrac{1}{6}\sqrt{3}a,\ \pm\tfrac{1}{2}\,a,\ 0\right),\ \text{and}\ \left(0,\ 0,\ \tfrac{1}{2}\sqrt{6}a\right). \qquad (20)$$

Since a tetrahedron is a PYRAMID with a triangular base, $V = \frac{1}{3} A_b h$, giving

$$V = \tfrac{1}{12}\sqrt{2}a^3. \qquad (21)$$

The DIHEDRAL ANGLE is

$$\alpha = \tan^{-1}\left(2\sqrt{2}\right) = \sin^{-1}\left(\tfrac{1}{3}\sqrt{3}\right) = \cos^{-1}\left(\tfrac{1}{3}\right)$$
$$\approx 70.53^\circ. \qquad (22)$$

By slicing a tetrahedron as shown above, a SQUARE can be obtained. This cut divides the tetrahedron into two congruent solids rotated by 90°. The projection of a tetrahedron can be an EQUILATERAL TRIANGLE or a SQUARE (Steinhaus 1983, pp. 191–192).

Now consider a general (not necessarily regular) tetrahedron, defined as a convex POLYHEDRON consisting of four (not necessarily identical) TRIANGULAR faces. Let the tetrahedron be specified by its VERTICES at (x_i, y_i, z_i) where $i = 1, ..., 4$. Then the VOLUME is given by

$$V = \frac{1}{3!}\begin{vmatrix} x_1 & y_1 & z_1 & 1 \\ x_2 & y_2 & z_2 & 1 \\ x_3 & y_3 & z_3 & 1 \\ x_4 & y_4 & z_4 & 1 \end{vmatrix}. \tag{23}$$

Specifying the tetrahedron by the three EDGE vectors **a**, **b**, and **c** from a given VERTEX, the VOLUME is

$$V = \frac{1}{3!}|\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c})|. \tag{24}$$

If the faces are congruent and the sides have lengths a, b, and c, then

$$V = \sqrt{\frac{(a^2 + b^2 - c^2)(a^2 + c^2 - b^2)(b^2 + c^2 - a^2)}{72}} \tag{25}$$

(Klee and Wagon 1991, p. 205). In general, if the edge between vertices i and j are of length d_{ij}, then the volume V is given by the CAYLEY-MENGER DETERMINANT

$$288V^2 = \begin{vmatrix} 0 & 1 & 1 & 1 & 1 \\ 1 & 0 & d_{12}^2 & d_{13}^2 & d_{14}^2 \\ 1 & d_{21}^2 & 0 & d_{23}^2 & d_{24}^2 \\ 1 & d_{31}^2 & d_{32}^2 & 0 & d_{34}^2 \\ 1 & d_{41}^2 & d_{42}^2 & d_{43}^2 & 0 \end{vmatrix}. \tag{26}$$

Consider an arbitrary TETRAHEDRON $A_1A_2A_3A_4$ with triangles $T_1 = \Delta A_2A_3A_4$, $T_2 = \Delta A_1A_3A_4$, $T_3 = \Delta A_1A_2A_4$, and $T_4 = A_1A_2A_3$. Let the areas of these triangles be s_1, s_2, s_3, and s_4, respectively, and denote the DIHEDRAL ANGLE with respect to T_i and T_j for $i \neq j =$ 1, 2, 3, 4 by θ_{ij}. Then the four face areas are connected by

$$s_k^2 = \sum_{\substack{j \neq k \\ 1 \leq j \leq 4}} s_j^2 - 2 \sum_{\substack{i,\, j \neq k \\ 1 \leq i,\, j \leq 4}} s_i s_j \cos \theta_{ij} \tag{27}$$

involving the six DIHEDRAL ANGLES (Dostor 1905, pp. 252–293; Lee 1997). This is a generalization of the LAW OF COSINES to the tetrahedron. Furthermore, for any $i \neq j = 1, 2, 3, 4$,

$$V = \frac{2}{3l_{ij}} s_i s_j \sin \theta_{ij}, \tag{28}$$

where l_{ij} is the length of the common edge of T_i and T_j (Lee 1997).

Let A be the set of edges of a tetrahedron and $P(A)$ the power set of A. Write $\bar{t}$ for the complement in A of an element $t \in P(A)$. Let F be the set of triples $\{x, y, z\} \in P(A)$ such that x, y, z span a face of the tetrahedron, and let G be the set of $(e \cap f) \cup \overline{(e \cup f)} \in P(A)$, so that $e, f \in F$ and $e \neq f$. In G, there are therefore three elements which are the pairs of opposite edges. Now define D, which associates to an edge x of length L the quantity $(L/\sqrt{12})^2$, p, which associates to an element $t \in P(A)$ the product of $D(x)$ for all $x \in t$, and s, which associates to t the sum of $D(x)$ for all $x \in t$. Then the VOLUME of a tetrahedron is given by

$$\sqrt{\sum_{t \in G}(s(\bar{t}) - s(t))p(t) - \sum_{t \in F} p(t)} \tag{29}$$

(P. Kaeser).

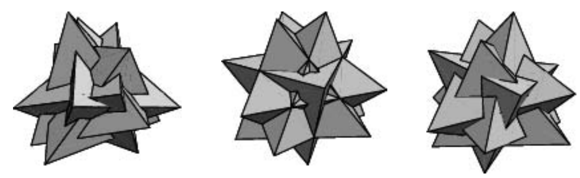
The analog of GAUSS'S CIRCLE PROBLEM can be asked for tetrahedra: how many LATTICE POINTS lie within a tetrahedron centered at the ORIGIN with a given INRADIUS (Lehmer 1940, Granville 1991, Xu and Yau 1992, Guy 1994).

There are a number of interesting and unexpected theorems on the properties of general (i.e., not necessarily regular) tetrahedron (Altshiller-Court 1979). If a plane divides two opposite edges of a tetrahedron in a given ratio, then it divides the volume of the tetrahedron in the same ratio (Altshiller-Court 1979, p. 89). It follows that any plane passing through a BIMEDIAN of a tetrahedron bisects the volume of the tetrahedron (Altshiller-Court 1979, p. 90).

Let the vertices of a tetrahedron be denoted A, B, C, and D, and denote the side lengths $BC = a$, $CA = b$, $AB = c$, $DA = a'$, $DB = b'$, and $DC = c'$. Then if Δ denotes the area of the triangle with sides of lengths by aa', bb', and cc', the VOLUME and CIRCUMRADIUS of the tetrahedron are related by the beautiful formula

$$6RV = \Delta \tag{30}$$

(Crelle 1821, p. 117; von Staudt 1860; Rouché and



Comberousse 1922, pp. 568–576 and 643–664; Altshiller-Court 1979, p. 250).

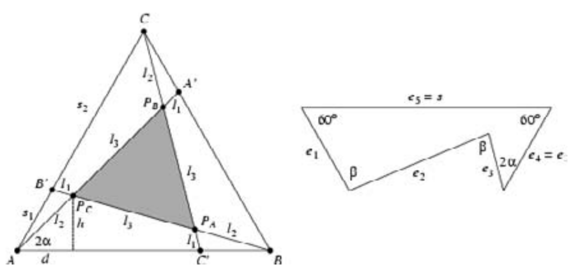
Tetrahedron 5-Compound



A POLYHEDRON COMPOUND composed of five TETRAHEDRA which is also one of the ICOSAHEDRON STELLATIONS. The 5×4 vertices of the tetrahedron are then 20 vertices of the DODECAHEDRON. Two tetrahedron 5-compounds of opposite CHIRALITY combine to make a TETRAHEDRON 10-COMPOUND (Cundy and Rollett 1989).

The diagram above shows pieces which can be assembled to form the tetrahedron 5-compound (Cundy and Rollett 1989). The construction itself is rather challenging, and involves constructing a base tetrahedron, placing a "cap" around one of the apexes, and affixing a triangular pyramid to the opposite face. Twelve pyramids with complicated bases are then constructed and attached edge-to-edge in chains of three. The four chains of pyramids are then arranged about the eight vertices of the original two tetrahedra, with the points of coincidence of the three pyramids in each chain attached such that they coincide with intersections of the original two tetrahedra such that five pyramids touch at a single point.

The position, size, and orientation of the pyramidal cap and pyramids are illustrated in the diagram above, where

$$\alpha=\cos^{-1}\left[\tfrac{1}{8}\left(3\sqrt{2}+\sqrt{10}\right)\right]\approx 22.2388^\circ \tag{1}$$

$$d=\tfrac{1}{8}\sqrt{23-3\sqrt{5}} \tag{2}$$

$$h=\tfrac{1}{8}\sqrt{3\left(3+\sqrt{5}\right)} \tag{3}$$

$$l_1=\tfrac{1}{2}\sqrt{\tfrac{1}{5}\left(3-\sqrt{5}\right)} \tag{4}$$

$$l_2=\tfrac{1}{2}\sqrt{2} \tag{5}$$

$$l_3=\tfrac{1}{2}\sqrt{3+\sqrt{5}} \tag{6}$$

$$s=\sqrt{3+\sqrt{5}} \tag{7}$$

$$s_1=\tfrac{1}{5}\sqrt{10} \tag{8}$$

$$s_2=\sqrt{\tfrac{1}{5}\left(7+3\sqrt{5}\right)}. \tag{9}$$

The edge lengths and angles of the cap are given by

$$\beta=\cos^{-1}\left(\tfrac{1}{4}\sqrt{7-3\sqrt{5}}\right)\approx 82.2388^\circ \tag{10}$$

$$e_1=\sqrt{3-\sqrt{5}} \tag{11}$$

$$e_2=\tfrac{1}{2}\left(5-\sqrt{5}\right) \tag{12}$$

$$e_3=\sqrt{7-3\sqrt{5}} \tag{13}$$

$$e_4=e_1 \tag{14}$$

$$e_5=s. \tag{15}$$

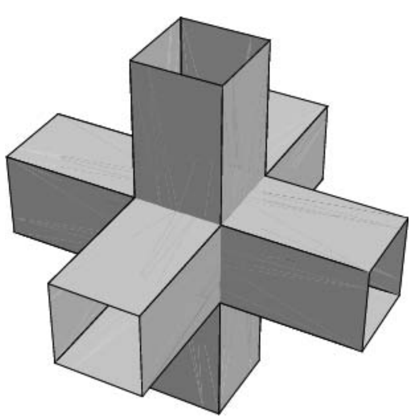
Tetrahedron Tetrahedron Picking



The expected VOLUME of a TETRAHEDRON with vertices chosen at random inside another TETRAHEDRON of unit volume appears to be numerically close to 1/57, but the exact analytic value is not known (Croft *et al.* 1991, p. 54). According to Solomon (1978, p. 124), "Explicit values for random points in non-spherical regions such as tetrahedrons, parallelepipeds, etc., have apparently not yet been successfully calculated."

Tetranacci Number

The tetranacci numbers are a generalization of the FIBONACCI NUMBERS defined by $T_0 = 0$, $T_1 = 1$, $T_2 = 1$, $T_3 = 2$, and the RECURRENCE RELATION

$$T_n = T_{n-1} + T_{n-2} + T_{n-3} + T_{n-4}$$

for $n \geq 4$. They represent the $n = 4$ case of the FIBONACCI N-STEP NUMBERS. The first few terms are 1, 1, 2, 4, 8, 15, 29, 56, 108, 208, ... (Sloane's A000078). The ratio of adjacent terms tends to 1.92756, which is the REAL ROOT of $x^5 - 2x^4 + 1 = 0$.

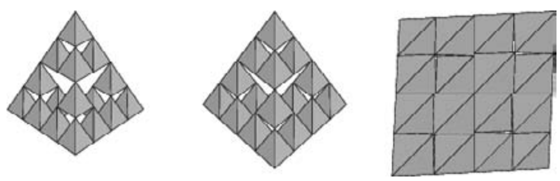
Tetrix

The 3-D analog of the SIERPINSKI SIEVE illustrated above, also called the SIERPINSKI SPONGE or SIERPINSKI TETRAHEDRON. Let N_n be the number of tetrahedra, L_n the length of a side, and A_n the fractional VOLUME of tetrahedra after the nth iteration. Then

$$N_n = 4^n \tag{1}$$

$$L_n = \left(\tfrac{1}{2}\right)^n = 2^{-n} \tag{2}$$

$$A_n = L_n^3 N_n = \left(\tfrac{1}{2}\right)^n. \tag{3}$$



The CAPACITY DIMENSION is therefore

$$d_{cap} = -\lim_{n\to\infty} \frac{\ln N_n}{\ln L_n} = -\lim_{n\to\infty} \frac{\ln(4^n)}{\ln(2^{-n})}$$

$$= \frac{\ln 4}{\ln 2} = \frac{2 \ln 2}{\ln 2} = 2, \quad (4)$$

so the tetrix has an INTEGER CAPACITY DIMENSION (which is one less than the DIMENSION of the 3-D TETRAHEDRA from which it is built), despite the fact that it is a FRACTAL.

The following illustrations demonstrate how the dimension of the tetrix can be the same as that of the PLANE by showing three stages of the rotation of a tetrix, viewed along one of its edges. In the last frame, the tetrix "looks" like the 2-D PLANE.

TANGENT

Th

HYPERBOLIC TANGENT

Thâbit ibn Kurrah Rule

A number OF THE FORM $3 \cdot 2^n - 1$ which is PRIME is sometimes called a Thâbit ibn Kurrah number. The indices for the first few such numbers are 1, 2, 3, 4, 6, 7, 11, 18, 34, 38, 43, 55, ... (Sloane's A002235). Riesel (1969) extended the search to $n \leq 1000$, and the largest known today is $n = 26459$.

The numbers arise in a beautiful result of Thâbit ibn Kurrah dating back to the tenth century (Woepcke 1852; Escott 1946; Dickson 1952, pp. 5 and 39; Borho 1972). Take $n \geq 2$ and suppose that

$$h = 3 \cdot 2^n - 1 \quad (1)$$

$$t = 3 \cdot 2^{n-1} - 1 \quad (2)$$

$$s = 9 \cdot 2^{2n-1} - 1 \quad (3)$$

are all PRIME. Then $(2^n ht,\ 2^n s)$ are an AMICABLE PAIR. This form was rediscovered by Fermat (1636) and Descartes (1638) and generalized by Euler to EULER'S RULE (Borho 1972).

In order for such numbers to exist, there must be prime $3 \cdot 2^n - 1$ for two consecutive n, leaving only the possibilities 1, 2, 3, 4, and 6, 7. Of these, s is prime for $n = 2$, 4, and 7, giving the amicable pairs (220, 284), (17296, 18416), and (9363584, 9437056).

In fact, various rules can be found that are analogous to Thâbit ibn Kurrah's. Denote a "Thâbit rule" by $T(b_1,\ b)2,\ p,\ F_1,\ F_2$ for given natural numbers b_1 and b_2, a prime p not dividing b_1, b_2, and polynomials $F_1(X),\ F_2(X) \in \mathbb{Z}[X]$. Then a necessary condition for the set of AMICABLE PAIRS $(m_1,\ m_2)$ of the form $m_i = p^n b_i q_i$ $(i = 1,\ 2)$ with q_1, q_2 prime and n a natural number to be infinite is that

$$\frac{p}{p-1} = \frac{b_1}{\sigma(b_1)} + \frac{b_2}{\sigma(b_2)}, \quad (4)$$

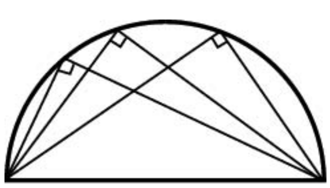
where $\sigma(n)$ is the divisor function (Borho 1972). As a result, $m_i = p^n b_i q_i$ $(i = 1,\ 2)$ form an AMICABLE PAIR, if for some $n \geq 1$, both

$$q_i = \frac{p^n (p-1)(b_1 + b_2)}{\sigma(b_i)} - 1 \quad (5)$$

for $i = 1$, 2 are prime integers not dividing $b_i p$ (Borho 1972).

The following table summarizes some of the known Thâbit ibn Kurrah rules $T(au,\ p, (u+1)X, (u+1)\sigma(u)X - 1)$ (Borho 1972, te Riele 1974).

a	u	$\sigma(u)$	p
2^2	$5 \cdot 11$	72	127
$3^2 \cdot 7 \cdot 13$	$5 \cdot 17$	108	193
$3^2 \cdot 5 \cdot 13$	$11 \cdot 19$	240	449
$3^2 \cdot 7^2 \cdot 13$	$5 \cdot 41$	252	457



$3^2 \cdot 7^2 \cdot 13 \cdot 19$	$5 \cdot 193$	1164	2129
$3^4 \cdot 5 \cdot 11$	$29 \cdot 89$	2700	5281
$3^2 \cdot 7 \cdot 13 \cdot 41 \cdot 163$	$5 \cdot 977$	5868	10753
$3^2 \cdot 5 \cdot 19 \cdot 37$	$7 \cdot 887$	7104	13313
$3^4 \cdot 7 \cdot 11 \cdot 29$	$13 \cdot 521$	7308	14081
$3^2 \cdot 7^2 \cdot 13 \cdot 19 \cdot 29$	$41 \cdot 173$	7308	14401
$3^2 \cdot 5 \cdot 13 \cdot 19$	$29 \cdot 569$	17100	33601
$3^2 \cdot 7^2 \cdot 13$	$5 \cdot 53 \cdot 97$	31752	57457
$3^2 \cdot 5^2 \cdot 13 \cdot 31$	$149 \cdot 449$	67500	134401
$3^3 \cdot 5^3 \cdot 13$	$149 \cdot 449$	67500	134401
$2 \cdot 7^2 \cdot 19 \cdot 23$	$11 \cdot 13523$	162288	311041
$3^4 \cdot 5 \cdot 11 \cdot 59$	$89 \cdot 5309$	477900	950401
$3^4 \cdot 5 \cdot 11^2 \cdot 71$	$709 \cdot 2129$	1512300	3021761
$3^2 \cdot 7^2 \cdot 11 \cdot 19 \cdot 43 \cdot 89$	$293 \cdot 22961$	6750828	13478401
$2^2 \cdot 31$	$17 \cdot 107 \cdot 4339$	8436960	16329601

Thales' Theorem

An ANGLE inscribed in a SEMICIRCLE is a RIGHT ANGLE.

See also RIGHT ANGLE, SEMICIRCLE

Theorem

A statement which can be demonstrated to be true by accepted mathematical operations and arguments. In general, a theorem is an embodiment of some general principle that makes it part of a larger theory. The process of showing a theorem to be correct is called a PROOF.

According to the Nobel Prize-winning physicist Richard Feynman (1985), any theorem, no matter how difficult to prove in the first place, is viewed as "TRIVIAL" by mathematicians once it has been proven. Therefore, there are exactly two types of mathematical objects: TRIVIAL ones, and those which have not yet been proven.

The late mathematician P. Erdos described a mathematician as "a machine for turning coffee into theorems" (Hoffman 1998, p. 7). R. Graham has estimated that upwards of 250,000 mathematical theorems are published each year (Hoffman 1998, p. 204).

Theory

A theory is a set of SENTENCES which is CLOSED under logical implication. That is, given any subset of SENTENCES $\{s_1, s_2, \ldots\}$ in the theory, if SENTENCE r is a logical consequence of $\{s_1, s_2, \ldots\}$, then r must also be in the theory.

Thiessen Polytope

VORONOI POLYGON

Thin Plate Spline

This entry contributed by SERGE BELONGIE

The thin plate spline is the two-dimensional analog of the CUBIC SPLINE in 1-D. It is the fundamental solution to the BIHARMONIC EQUATION, and has the form

$$U(r) = r^2 \ln r.$$

Given a set of data points, a weighted combination of thin plate splines centered about each data point gives the interpolation function that passes through the points exactly while minimizing the so-called "bending energy." Bending energy is defined here as the integral over $\mathbb{R}^2$ of the squares of the second derivatives,

$$I[f(x,\ y)] = \iint_{\mathbb{R}^2} f_{xx}^2 + 2f_{xy}^2 + f_{yy}^2\ dx\ dy.$$

Regularization may be used to relax the requirement that the interpolant pass through the data points exactly.

The name "thin plate spline" refers to a physical analogy involving the bending of a thin sheet of metal. In the physical setting, the deflection is in the z direction, orthogonal to the plane. In order to apply this idea to the problem of coordinate transformation, one interprets the lifting of the plate as a displacement of the x or y coordinates within the plane. Thus, in general, two thin plate splines are needed to specify a 2-D coordinate transformation.

Third Kind

In the theory of special functions, a class of functions is said to be "of the third kind" if it is similar to but distinct from previously defined functions already defined to be of the FIRST and SECOND KINDS. The only common functions of the third kind are the ELLIPTIC INTEGRAL OF THE THIRD KIND $\mathbf{II}(n; \phi, k)$ and the Bessel function of the third kind (more commonly called the HANKEL FUNCTION).

Thompson Lamp Paradox

A lamp is turned on for 1/2 minute, off for 1/4 minute, on for 1/8 minute, etc. At the end of one minute, the lamp switch will have been moved $\aleph_0$ times, where $\aleph_0$ is ALEPH-0. Will the lamp be on or off? This PARADOX is actually nonsensical, since it is equivalent to asking if the "last" INTEGER is EVEN or ODD.

Three Conics Theorem

If three conics pass through two given points Q and Q', then the lines joining the other two intersections of each pair of conics $P_{ij}P'_{ij}$ are CONCURRENT at a point X (Evelyn 1974, p. 15). The converse states that if two conics E_2 and E_3 meet at four points Q, Q', P_1, and Q_1, and if P_2Q_2 and P_3Q_3 are chords of E_3 and E_2, respectively, which meet on P_1Q_1, then the six points lie on a conic. The dual of the theorem states that if three conics share two common tangents, then their remaining pairs of common tangents intersect at three collinear points.

If the points Q and Q' are taken as the POINTS AT INFINITY, then the theorem reduces to the theorem that RADICAL LINES of three CIRCLES are CONCURRENT in a point known as the RADICAL CENTER (Evelyn 1974, p. 15).

If two of the points P_{ij} and P'_{ij} are taken as the POINTS AT INFINITY, then the theorem becomes that if two circles C_1 and C_2 pass through two points Q and Q' on a conic E, then the lines determined by the pair of intersections of each circle with the conic are parallel (Evelyn 1974, p. 15).

Three-Choice Polygon

A LATTICE POLYGON formed by a THREE-CHOICE WALK. The anisotropic perimeter and area generating function

$$G(x, y, q) = \sum m \geq 1 \sum_{n \geq 1} \sum_{a \geq a} C(m, n, a) x^m y^n q^a,$$

where $C(m, n, a)$ is the number of polygons with $2m$ horizonal bonds, $2n$ vertical bonds, and area a, is not yet known in closed form, but it can be evaluated in polynomial time (Conway *et al.* 1997, Bousquet-Mélou 1999). The perimeter-generating function $G(x, x, 1)$ has a logarithmic singularity and so is not algebraic, but is known to be D-finite (Conway *et al.* 1997, Bousquet-Mélou 1999).

The anisotropic area and perimeter generating function $G(x, y, q)$ satisfies an inversion relation OF THE FORM

$$G(x, y, q) + y^2 G(x/y, 1/y, 1/q)$$

(Bousquet-Mélou *et al.* 1999).

Three-Choice Walk

A SELF-AVOIDING WALK in which steps may be to the left, right, or straight ahead after a vertical step, but only straight ahead of to the left after a horizontal step. A LATTICE POLYGON formed by a three-choice walk is called a THREE-CHOICE POLYGON.

Thue Constant

The base-2 TRANSCENDENTAL NUMBER

$$0.110110111110110111111\ldots_2,$$

where the nth bit is 1 if n is not divisible by 3 and is the complement of the $(n/3)$th bit if n is divisible by 3. It is also given by the SUBSTITUTION MAP

$$0 \to 111$$

$$1 \to 110.$$

In decimal, the Thue constant equals 0.8590997969....

See also RABBIT CONSTANT, THUE-MORSE CONSTANT

Thue Equation

This entry contributed by KEVIN O'BRYANT

A Thue equation is a DIOPHANTINE EQUATION of the form

$$A_n x^n + A_{n-1} x^{n-1} y + A_{n-2} x^{n-2} y^2 + \ldots + A_0 y^n = M,$$

with $n \geq 3, A_i \in \mathbb{Z}, M \neq 0 \in Z$, and x, y unknown integer variables.

Thue (1909) proved that such an equation has only finitely many solutions, but it was not until much later that Tzanakis and de Weger (1989) gave a practical algorithm for finding bounds on $|x|$ and $|y|$. Although these bounds can be astronomically large in some cases, they are typically small enough to allow an exhaustive search for all solutions.

See also Diophantine Equation

Thue-Morse Constant

The constant also called the parity constant and defined by

$$P \equiv \tfrac{1}{2} \sum_{n=0}^{\infty} P(n) 2^{-n} = 0.4124540336401075977\ldots \quad (1)$$

(Sloane's A014571), where $P(n)$ is the parity of n. Dekking (1977) proved that the Thue-Morse constant is transcendental, and Allouche and Shallit give a complete proof correcting a minor error of Dekking.

The Thue-Morse constant can be written in base 2 by stages by taking the previous iteration a_n, taking the complement $\overline{a_n}$, and appending, producing

$$\begin{aligned} a_0 &= 0.0_2 \\ a_1 &= 0.01_2 \\ a_2 &= 0.0110_2 \\ a_3 &= 0.01101001_2 \\ a_4 &= 0.0110100110010110_2. \end{aligned} \quad (2)$$

This can be written symbolically as

$$a_{n+1} = a_n + \overline{a_n} \cdot 2^{-2^n} \quad (3)$$

with $a_0 = 0$. Here, the complement is the number $\overline{a_n}$ such that $a_n + \overline{a_n} = 0.\underbrace{11\ldots1}_{2^n}{}_2$, which can be found from

$$a_n + \overline{a_n} = \sum_{k=1}^{2n} \left(\tfrac{1}{2}\right)^k = \frac{1-\left(\tfrac{1}{2}\right)^{2^n}}{1-\tfrac{1}{2}} - 1 = 1 - 2^{-2^n}. \quad (4)$$

Therefore,

$$\overline{a_n} = 1 - 2^{-2^n} - a_n, \quad (5)$$

and

$$\begin{aligned} a_{n+1} &= a_n + \left(1 - 2^{-2^n} - a_n\right) 2^{-2^n} \quad (6) \\ &= 2^{-2^{n+1}} \left(2^{2^n - 1}\right)\left(1 - 2^{2^n} a_n\right). \quad (7) \end{aligned}$$

The regular continued fraction for the Thue-Morse constant is [0 2 2 2 1 4 3 5 2 1 4 2 1 5 44 1 4 1 2 4 1 1 1 5 14 1 50 15 5 1 1 1 4 2 1 4 1 43 1 4 1 2 1 3 16 1 2 1 2 1 50 1 2 424 1 2 5 2 1 1 1 5 5 2 22 5 1 1 1 1274 3 5 2 1 1 1 4 1 1 15 154 7 2 1 2 2 1 2 1 1 50 1 4 1 2 867374 1 1 1 5 5 1 1 6 1 2 7 2 1650 23 3 1 1 1 2 5 3 84 1 1 1 1284 ...] (Sloane's A014572), and seems to continue with sporadic large terms in suspicious-looking patterns. A nonregular continued fraction is

$$P = \cfrac{1}{3 - \cfrac{1}{2 - \cfrac{1}{4 - \cfrac{3}{16 - \cfrac{15}{256 - \cfrac{255}{65536 - \ldots}}}}}}. \quad (8)$$

A related infinite product is

$$4P = 2 - \frac{1 \cdot 3 \cdot 15 \cdot 255 \cdot 65535 \cdots}{2 \cdot 4 \cdot 16 \cdot 256 \cdot 65536 \cdots}. \quad (9)$$

The sequence $a_\infty = 01101001100101101001011001\ldots$ (Sloane's A010060) is known as the Thue-Morse sequence.

Thue-Morse Sequence

The INTEGER SEQUENCE (also called the MORSE-THUE SEQUENCE)

$$01101001100101101001011001101001\ldots \quad (1)$$

(Sloane's A010060) which arises in the THUE-MORSE CONSTANT. It can be generated from the SUBSTITUTION MAP

$$0 \to 01 \quad (2)$$

$$1 \to 10 \quad (3)$$

starting with 0 as follows:

$$0 \to 01 \to 0110 \to 01101001 \to \ldots \quad (4)$$

Writing the sequence as a POWER SERIES over the FINITE FIELD GF(2),

$$F(x) = 0 + 1x + 1x^2 + 0x^3 + 1x^4 + \ldots, \quad (5)$$

then F satisfies the quadratic equation

$$(1+x)F^2 + F = \frac{x}{1+x^2} \pmod 2. \quad (6)$$

This equation has two solutions, F and F', where F' is the complement of F, i.e.,

$$F + F' = 1 + x + x^2 + x^3 + \ldots = \frac{1}{1+x}, \quad (7)$$

which is consistent with the formula for the sum of the roots of a quadratic. The equality (6) can be demonstrated as follows. Let (*abcdef*...) be a shorthand for the POWER SERIES

$$a + bx + cx^2 + dx^3 + \ldots, \quad (8)$$

so $F(x)$ is (0110100110010110...). To get F^2, simply use the rule for squaring POWER SERIES over GF(2)

$$(A+B)^2 = A^2 + B^2 \pmod 2, \quad (9)$$

which extends to the simple rule for squaring a POWER SERIES

$$(a_0 + a_1 x + a_2 x^2 + \ldots)^2 = a_0 + a_1 x^2 + a_2 x^4 + \ldots \pmod 2, \quad (10)$$

i.e., space the series out by a factor of 2, (0 1 1 0 1 0 0 1 ...), and insert zeros in the ODD places to get

$$F^2 = (0010100010000010\ldots). \quad (11)$$

Then multiply by x (which just adds a zero at the front) to get

$$xF^2 = (00010100010000010\ldots). \quad (12)$$

Adding to F^2 gives

$$(1+x)F^2 = (0011110011000011\ldots). \quad (13)$$

This is the first term of the quadratic equation, which is the Thue-Morse sequence with each term doubled up. The next term is F, so we have

$$(1+x)F^2 = (0011110011000011\ldots) \quad (14)$$

$$F = (0110100110010110\ldots). \quad (15)$$

The sum is the above two sequences XORed together (there are no CARRIES because we're working over GF(2)), giving

$$(1+x)F^2 + F = (0101010101010101\ldots). \quad (16)$$

We therefore have

$$(1+x)F^2 + F = \frac{x}{1+x^2} = x + x^3 + x^5 + x^7 + x^9 + x^{11} + \ldots \pmod 2. \quad (17)$$

The Thue-Morse sequence is an example of a cube-free sequence on two symbols (Morse and Hedlund 1944), i.e., it contains no substrings OF THE FORM WWW, where W is any WORD. For example, it does not contain the WORDS 000, 010101 or 010010010. In fact, the following stronger statement is true: the Thue-Morse sequence does not contain any substrings OF THE FORM WWa, where a is the first symbol of W. We can obtain a SQUAREFREE sequence on three symbols by doing the following: take the Thue-Morse sequence 0110100110010110... and look at the sequence of WORDS of length 2 that appear: 01 11 10 01 10 00 01 11 10 .... Replace 01 by 0, 10 by 1, 00 by 2 and 11 by 2 to get the following: 021012021.... Then this SEQUENCE is SQUAREFREE (Morse and Hedlund 1944).

The Thue-Morse sequence has important connections with the GRAY CODE. Kindermann generates fractal music using the SELF-SIMILARITY of the Thue-Morse sequence.

Thue's Remainder Theorem

THUE'S THEOREM

Thue's Theorem

If $n > 1$, $(a, n) = 1$ (i.e., a and n are RELATIVELY PRIME), and m is the least integer $> \sqrt{n}$, then there exist an x and y such that

$$ay \equiv \pm x \pmod{n}$$

where $0 < x < m$ and $0 < y < m$ (Nagell 1951, pp. 122–124; Shanks 1993, p. 161)

THUE-SIEGEL-ROTH THEOREM

Thurston's Geometrization Conjecture

Thurston's conjecture has to do with geometric structures on 3-D MANIFOLDS. Before stating Thurston's conjecture, some background information is useful. 3-dimensional MANIFOLDS possess what is known as a standard 2-level DECOMPOSITION. First, there is the CONNECTED SUM DECOMPOSITION, which says that every COMPACT 3-MANIFOLD is the CONNECTED SUM of a unique collection of PRIME 3-MANIFOLDS.

The second DECOMPOSITION is the JACO-SHALEN-JOHANNSON TORUS DECOMPOSITION, which states that irreducible orientable COMPACT 3-MANIFOLDS have a CANONICAL (up to ISOTOPY) minimal collection of disjointly EMBEDDED incompressible TORI such that each component of the 3-MANIFOLD removed by the TORI is either "atoroidal" or "Seifert-fibered."

Thurston's conjecture is that, after you split a 3-MANIFOLD into its CONNECTED SUM and then JACO-SHALEN-JOHANNSON TORUS DECOMPOSITION, the remaining components each admit exactly one of the following geometries:

1. EUCLIDEAN GEOMETRY,
2. HYPERBOLIC GEOMETRY,
3. SPHERICAL GEOMETRY,
4. the GEOMETRY of $\mathbb{S}^2 + \mathbb{R}$,
5. the GEOMETRY of $\mathbb{H}^2 + \mathbb{R}$,
6. the GEOMETRY of SL_2R,
7. NIL GEOMETRY, or
8. SOL GEOMETRY.

Here, $\mathbb{S}^2$ is the 2-SPHERE and $\mathbb{H}^2$ is the HYPERBOLIC PLANE. If Thurston's conjecture is true, the truth of the POINCARÉ CONJECTURE immediately follows.

See also CONNECTED SUM DECOMPOSITION, EUCLIDEAN GEOMETRY, HYPERBOLIC GEOMETRY, JACO-SHALEN-JOHANNSON TORUS DECOMPOSITION, NIL GEOMETRY, POINCARÉ CONJECTURE, SOL GEOMETRY, SPHERICAL GEOMETRY

Thwaites Conjecture

COLLATZ PROBLEM

Ticktacktoe

TIC-TAC-TOE

Tic-Tac-Toe

The usual game of tic-tac-toe (also called TICKTACKTOE) is 3-in-a-row on a 3×3 board. However, a generalized N-IN-A-ROW on an $u \times v$ board can also be considered. For $n = 1$ and 2 the first player can always win. If the board is at least 3×4, the first player can win for $n = 3$.

However, for TIC-TAC-TOE which uses a 3×3 board, a draw can always be obtained. If the board is at least 4×30, the first player can win for $n = 4$. For $n = 5$, a draw can always be obtained on a 5×5 board, but the first player can win if the board is at least 15×15. The cases $n = 6$ and 7 have not yet been fully analyzed for an $n \times n$ board, although draws can always be forced for $n = 8$ and 9. On an $\infty \times \infty$ board, the first player can win for $n = 1$, 2, 3, and 4, but a tie can always be forced for $n \geq 8$. For $3 \times 3 \times 3$ and $4 \times 4 \times 4$, the first player can always win (Gardner 1979).

Tightly Embedded

Q is said to be tightly embedded if $|Q \cap Q^g|$ is ODD for all $g \in G - N_G(Q)$, where $N_G(Q)$ is the NORMALIZER of Q in G.

Tilde

The mark ~ placed on top of a symbol to indicate some special property. $\tilde{x}$ is voiced "x-tilde." The tilde symbol is commonly used to denote an operator, e.g., the DIFFERENTIAL OPERATOR $\tilde{D}$. In informal usage, "tilde" is often instead voiced as "twiddle." It is also sometimes used to denote a MEDIAN (Kenney and Keeping 1962, p. 211).

See also MEDIAN (STATISTICS), DIFFERENTIAL OPERATOR

Tiling

A plane-filling arrangement of plane figures or its generalization to higher dimensions. Formally, a tiling is a collection of disjoint open sets, the closures of which cover the plane. Given a single tile, the so-called first CORONA is the set of all tiles that have a common boundary point with the tile (including the original tile itself).

WANG'S CONJECTURE (1961) stated that if a set of tiles tiled the plane, then they could always be arranged to do so periodically. A periodic tiling of the PLANE by POLYGONS or SPACE by POLYHEDRA is called a TESSELLATION. The conjecture was refuted in 1966 when R. Berger showed that an aperiodic set of 20,426 tiles exists. By 1971, R. Robinson had reduced the number to six and, in 1974, R. Penrose discovered an aperiodic set (when color-matching rules are included) of two tiles: the so-called PENROSE TILES. (Penrose also sued the Kimberly Clark Corporation over their quilted toilet paper, which allegedly resembles a Penrose aperiodic tiling; Mirsky 1997.)

It is not known if there is a single aperiodic tile. The number of tilings possible for convex irregular POLYGONS are given in the above table.

n	name	known tilings
3	TRIANGLE TILING	all
4	QUADRILATERAL TILING	all
5	PENTAGON TILING	14
6	HEXAGON TILING	3

There are no tilings for *identical* convex n-gons for $n \geq 7$, although non-identical convex heptagons can tile the plane (Steinhaus 1983, p. 77; Gardner 1984, pp. 248–249).

Tiling Theorem

Due to Lebesgue and Brouwer. If an n-D figure is covered in any way by sufficiently small subregions, then there will exist points which belong to at least $n+1$ of these subareas. Moreover, it is always possible to find a covering by arbitrarily small regions for which no point will belong to more than $n+1$ regions.

Time Series Analysis

Analysis of data ordered by the time the data were collected (usually spaced at equal intervals), called a time series. Common examples of a time series are daily temperature measurements, monthly sales, and yearly population figures. The goals of time series analysis are to describe the process generating the data, and to forecast future values.

Times

The operation of MULTIPLICATION, i.e., a times b. Various notations are $a \times b$, $a \cdot b$, ab, and $(a)(b)$. The "multiplication sign" $\times$ is based on SAINT ANDREW'S CROSS (Bergamini 1969). Floating point MULTIPLICATION is sometimes denoted $\otimes$.

T-Integration

A fast, accurate, and numerically stable NUMERICAL INTEGRATION formula given by

$$X_n = X_{n-1} + TG\left[P\left(\frac{dX}{dt}\right)_n + (1-P)\left(\frac{dX}{dt}\right)_{n-1}\right],$$

where X is the integral, dX/dt is the integrand, P and G are "phase " and "gain" tuning parameters, n refers to the number of the iteration being evaluated, and T is the integration step size. For $G = 1$, varying

P from 0 to 2 gives many classical first-order integrators:

1. $G=1$ and $P=0$: Euler integrator,
2. $G=1$ and $P=1/2$: TRAPEZOIDAL RULE,
3. $G=1$ and $P=1$: Rectangular rule,
4. $G=1$ and $P=3/2$: ADAMS' METHOD.

Titanic Prime

A PRIME with ≥ 1000 DIGITS. As of 1990, there were more than 1400 known (Ribenboim 1990). The table below gives the number of known titanic primes as a function of year end.

Year	Titanic Primes
1992	2254
1993	9166
1994	9779
1995	12391

Titchmarsh Theorem

If $f(\omega)$ is SQUARE INTEGRABLE over the REAL ω-axis, then any one of the following implies the other two:

1. The FOURIER TRANSFORM $F(t)=\mathscr{F}[f(\omega)]$ is 0 for $t<1$.
2. Replacing ω by $z\equiv x+iy$, the function $f(z)$ is analytic in the COMPLEX PLANE z for $y>0$ and approaches $f(x)$ almost everywhere as $y\to 0$. Furthermore, $\int_{-\infty}^{\infty}|f(x+iy)|^2\,dx<k$ for some number k and $y>0$ (i.e., the integral is bounded).
3. The REAL and IMAGINARY PARTS of $F(z)$ are HILBERT TRANSFORMS of each other

(Bracewell 1999, Problem 8, p. 273).

Tits Group

A FINITE SIMPLE GROUP which is a SUBGROUP of the TWISTED CHEVALLEY GROUP ${}^2F_4(2)$.

Toeplitz Matrix

Given $2n-1$ numbers a_k, where $k=-n+1, ..., -1, 0, 1, ..., n-1$, a Toeplitz matrix is a MATRIX which has constant values along negative-sloping diagonals, i.e., a matrix OF THE FORM

$$\begin{bmatrix} a_0 & a_{-1} & a_{-2} & \cdots & a_{-n+1} \\ a_1 & a_0 & a_{-1} & \ddots & \vdots \\ a_2 & a_1 & a_0 & \ddots & a_{-2} \\ \vdots & \ddots & \ddots & \ddots & a_{-1} \\ a_{n-1} & \cdots & a_2 & a_1 & a_0 \end{bmatrix}.$$

MATRIX EQUATIONS OF THE FORM

$$\sum_{j=1}^{n} a_{i-j}x_j = y_i$$

can be solved with $\mathcal{O}(n^2)$ operations. Typical problems modelled by Toeplitz matrices include the numerical solution of certain differential and integral equations (regularization of inverse problems), the computation of SPLINES, TIME SERIES ANALYSIS, signal and image processing, MARKOV CHAINS, and QUEUING THEORY (Bini 1995).

Togliatti Surface

Togliatti (1940, 1949) showed that QUINTIC SURFACES having 31 ORDINARY DOUBLE POINTS exist, although he did not explicitly derive equations for such surfaces. Beauville (1978) subsequently proved that 31 double points are the maximum possible, and quintic surfaces having 31 ORDINARY DOUBLE POINTS are therefore sometimes called Togliatti surfaces. van Straten (1993) subsequently constructed a 3-D family of solutions and in 1994, Barth derived the example known as the DERVISH.

Tomography

Tomography is the study of the reconstruction of 2- and 3-dimensional objects from 1-dimensional slices. The RADON TRANSFORM is an important tool in tomography.

Rather surprisingly, there exist certain sets of four directions in Euclidean n-space such that X-rays of a convex body in these directions distinguish it from all other convex bodies.

Nordstrand, T. "Surfaces." http://www.uib.no/people/nfytn/surfaces.htm.

Top-Dimensional Form

In an EXTERIOR ALGEBRA $\wedge V$, a top-dimensional form has degree n where $n = \dim V$. Any form of higher degree must be zero. For example, if $V = \mathbb{R}^4$ then

$$\alpha = e_1 \wedge e_2 \wedge e_3 \wedge e_4$$

is a top-dimensional form, and any other top-dimensional form is $\lambda\alpha$ for some λ.

See also DIFFERENTIAL k-FORM, EXTERIOR ALGEBRA, ORIENTATION (VECTOR SPACE), VOLUME FORM

Topological Basis

A topological basis is a SUBSET B of a SET T in which all other OPEN SETS can be written as UNIONS or finite

INTERSECTIONS of B. For the REAL NUMBERS, the SET of all OPEN INTERVALS is a basis.

Topological Completion

The topological completion C of a FIELD F with respect to the ABSOLUTE VALUE $|\cdot|$ is the smallest FIELD containing F for which all CAUCHY SEQUENCES or rationals converge.

Topological Groupoid

A topological groupoid over B is a GROUPOID G such that B and G are TOPOLOGICAL SPACES and α, β, and multiplication are continuous maps. Here, α and β are maps from G onto $\mathbb{R}^2$ with $\alpha : (x, \gamma, y) \mapsto x$ and $\beta : (x, \gamma, y) \mapsto y$.

See also GROUPOID, TOPOLOGICAL SPACE

References

Weinstein, A. "Groupoids: Unifying Internal and External Symmetry." *Not. Amer. Math. Soc.* **43**, 744–752, 1996.

Topological Manifold

A TOPOLOGICAL SPACE M satisfying some separability (i.e., it is a HAUSDORFF SPACE) and countability (i.e., it is a PARACOMPACT SPACE) conditions such that every point $p \in M$ has a NEIGHBORHOOD homeomorphic to an OPEN SET in $\mathbb{R}^n$ for some $n \geq 0$. Every SMOOTH MANIFOLD is a topological manifold, but not necessarily vice versa. The first nonsmooth topological manifold occurs in 4-D.

Nonparacompact manifolds are of little use in mathematics, but non-Hausdorff manifolds do occasionally arise in research (Hawking and Ellis 1975). For manifolds, Hausdorff and second countable are equivalent to Hausdorff and paracompact, and both are equivalent to the manifold being embeddable in some large-dimensional Euclidean space.

Topological Sort

A topological sort is a PERMUTATION p of the vertices of a GRAPH such that an edge $\{i, j\}$ implies that i appears before j in p (Skiena 1990, p. 208). Only DIRECTED ACYCLIC GRAPHS can be topologically sorted. The topological sort of a graph can be computed using `TopologicalSort[g]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

Skiena, S. "Topological Sorting." §5.4.3 in *Implementing Discrete Mathematics: Combinatorics and Graph Theory*

with Mathematica. Reading, MA: Addison-Wesley, pp. 208–209, 1990.

Topological Space

A SET X for which a TOPOLOGY T has been specified is called a topological space (Munkres 1975, p. 76).

In the chapter "Point Sets in General Spaces" Hausdorff (1914) defined his concept of a topological space based on the four HAUSDORFF AXIOMS.

1. To each point x there corresponds at least one neighborhood $U(x)$, and $U(x)$ contains x.
2. If $U(x)$ and $V(x)$ are neighborhoods of the same point x, then there exists a neighborhood $W(x)$ of x such that $W(x)$ is a subset of the union of $U(x)$ and $V(x)$.
3. If y is a point in $U(x)$, then there exists a neighborhood $U(y)$ of y such that $U(y)$ is a subset of $U(x)$.
4. For distinct points x and y, there exist two disjoint neighborhoods $U(x)$ and $U(y)$.

Topological Tree

SERIES-REDUCED TREE

Topological Vector Space

A VECTOR SPACE with a HAUSDORFF TOPOLOGY such that the operations of VECTOR ADDITION and SCALAR MULTIPLICATION are CONTINUOUS. The interesting examples are infinite-dimensional spaces, such as a space of functions. For example, a HILBERT SPACE and a BANACH SPACE are topological vector spaces.

The choice of topology reflects what is meant by convergence of functions. For instance, for functions whose integrals converge, the BANACH SPACE $L^1(X)$, one of the L^p-SPACES, is used. But if one is interested in POINTWISE CONVERGENCE, then no norm will suffice. Instead, for each $x \in X$ define the SEMINORM

$$\|f\|_x = |f(x)|$$

on the vector space of functions on X. The seminorms define a topology, the smallest one in which the seminorms are CONTINUOUS. So $\lim f_n = f$ is equivalent to $\lim f_n(x) = f(x)$ for all $x \in X$, i.e., POINTWISE CONVERGENCE. In a similar way, it is possible to define a topology for which CONVERGENCE means UNIFORM CONVERGENCE on COMPACT SETS.

See also BANACH SPACE, HILBERT SPACE, SEMINORM, TOPOLOGICAL SPACE, VECTOR SPACE

References

Topologically Conjugate

Two MAPS ϕ, $\psi : M \to M$ are said to be topologically conjugate if there EXISTS a HOMEOMORPHISM $h : M \to M$ such that $\phi \circ h = h \circ \psi$, i.e., h maps ψ-orbits onto ϕ-orbits. Two maps which are topologically conjugate cannot be distinguished topologically.

See also ANOSOV DIFFEOMORPHISM, STRUCTURALLY STABLE

Topologically Transitive

A FUNCTION f is topologically transitive if, given any two intervals U and V, there is some POSITIVE INTEGER k such that $f^k(U) \cap V \neq \emptyset$. Vaguely, this means that neighborhoods of points eventually get flung out to "big" sets so that they don't necessarily stick together in one localized clump.

See also CHAOS

Topology

Topology is the mathematical study of properties of objects which are preserved through deformations, twistings, and stretchings. (Tearing, however, is not allowed.) A CIRCLE is topologically equivalent to an ELLIPSE (into which it can be deformed by stretching) and a SPHERE is equivalent to an ELLIPSOID. Continuing along these lines, the SPACE of all positions of the minute hand on a clock is topologically equivalent to a CIRCLE (where SPACE of all positions means "the collection of all positions"). Similarly, the SPACE of all positions of the minute and hour hands is equivalent to a TORUS. The SPACE of all positions of the hour, minute and second hands form a 4-D object that cannot be visualized quite as simply as the former objects since it cannot be placed in our 3-D world, although it can be visualized by other means.

There is more to topology, though. Topology began with the study of curves, surfaces, and other objects in the plane and 3-space. One of the central ideas in topology is that spatial objects like CIRCLES and SPHERES can be treated as objects in their own right, and knowledge of objects is independent of how they are "represented" or "embedded" in space. For example, the statement "if you remove a point from a CIRCLE, you get a line segment" applies just as well to the CIRCLE as to an ELLIPSE, and even to tangled or

knotted CIRCLES, since the statement involves only topological properties.

Topology has to do with the study of spatial objects such as curves, surfaces, the space we call our universe, the space-time of general relativity, fractals, knots, manifolds (objects with some of the same basic spatial properties as our universe), phase spaces that are encountered in physics (such as the space of hand-positions of a clock), symmetry groups like the collection of ways of rotating a top, etc.

The "objects" of topology are often formally defined as TOPOLOGICAL SPACES. If two objects have the same topological properties, they are said to be HOMEOMORPHIC (although, strictly speaking, properties that are not destroyed by stretching and distorting an object are really properties preserved by ISOTOPY, not HOMEOMORPHISM; ISOTOPY has to do with distorting embedded objects, while HOMEOMORPHISM is intrinsic).

Topology is divided into ALGEBRAIC TOPOLOGY (also called COMBINATORIAL TOPOLOGY), DIFFERENTIAL TOPOLOGY, and LOW-DIMENSIONAL TOPOLOGY.

There is also a formal definition for a topology defined in terms of set operations. A SET X along with a collection T of SUBSETS of it is said to be a topology if the SUBSETS in T obey the following properties:

1. The (trivial) subsets X and the EMPTY SET $\emptyset$ are in T.
2. Whenever sets A and B are in T, then so is $A \cap B$.
3. Whenever two or more sets are in T, then so is their UNION

(Bishop and Goldberg 1980). This definition can be used to enumerate the topologies on n symbols in *Mathematica* using the following code snippet.

```
<<DiscreteMath`Combinatorica`;        Topolo-
gyQ[x_List,t_List]:=Module[{},
   MemberQ[t,x]&&MemberQ[t,{}]&&
      And@@(MemberQ[t,#]&/@Intersection@@@KSub-
sets[t,2])&&
   And@@(MemberQ[t,#]&/@Union@@@Subsets[t])
  ]  Topologies[n_]:=Module[{r=Range[n]},
   Select[Subsets[Subsets[r]],TopologyQ[r,#]&]
  ]
```

For example, the unique topology of order 1 is $\{\emptyset, \{1\}\}$, which the four topologies of order 2 are $\{\emptyset, \{1\}, \{1, 2\}\}$, $\{\emptyset, \{1, 2\}\}$, $\{\emptyset, \{1, 2\}, \{2\}\}$, and $\{\emptyset, \{1\}, \{2\}, \{1, 2\}\}$. The numbers of topologies on sets of cardinalities $n = 1, 2, ...$ are 1, 4, 29, 355, 6942, ... (Sloane's A000798).

A SET X for which a topology T has been specified is called a TOPOLOGICAL SPACE (Munkres 1975, p. 76). For example, the SET $X = \{1, 2, 3, 4\}$ together with the SUBSETS $T = \{\emptyset, \{1\}, \{2, 3, 4\}, \{1, 2, 3, 4\}\}$ comprises a topology, and X is a TOPOLOGICAL SPACE.

Topologies can be built up from TOPOLOGICAL BASES. For the REAL NUMBERS, the topology is the UNION of OPEN INTERVALS.

Toric Section

A curve obtained by slicing a TORUS (generally a HORN TORUS) with a plane. A SPIRIC SECTION is a special case of a toric section in which the slicing plane is perpendicular to both the midplane of the torus and to the plane $x = 0$.

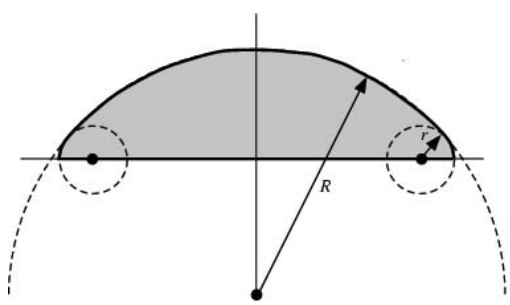
For planes parallel to the xy-plane, the toric sections are a single circle (for $z = 0$) or two concentric circles (for $0 < |z| \leq a$). For planes containing the z-AXIS, the section is two equal circles.

Toric sections at oblique angles can be more complicated, passing from a crescent shape, through a U-

shape, and into two disconnected kidney-shaped curves.

See also Spiric Section, Torus

Toric Variety



Let $m_1, m_2, ..., m_n$ be distinct primitive elements of a 2-D lattice M such that $\det(m_i,\ m_{i+1}) > 0$ for $i = 1$, ..., $n-1$. Each collection $\Gamma = \{m_1,\ m_2,\ \ldots,\ m_n\}$ then forms a set of rays of a unique complete fan in M, and therefore determines a 2-D toric variety X_Γ.

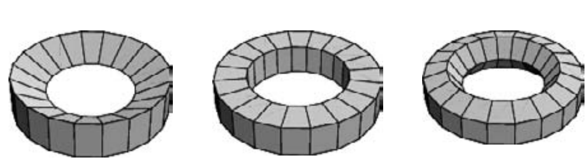
Torispherical Dome



A torispherical dome is the surface obtained from the intersection of a spherical cap with a tangent torus, as illustrated above. The radius of the sphere R is called the "crown radius," and the radius of the torus is called the "knuckle radius." Torispherical domes are used to construct pressure vessels.

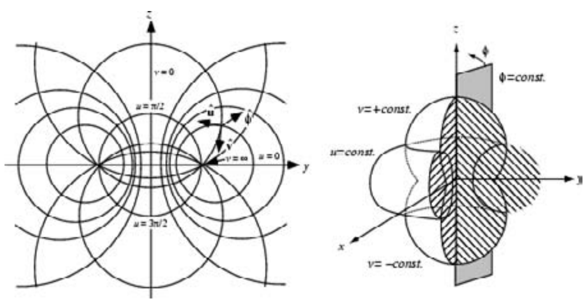
Torn Square Fractal

Cesàro Fractal

Toroid



A surface of revolution obtained by rotating a closed plane curve about an axis parallel to the plane which does not intersect the curve. The simplest toroid is the torus. The word is also used to refer to a toroidal polyhedron (Gardner 1975).

Toroidal Coordinates

A system of curvilinear coordinates for which several different notations are commonly used. In this work $(u,\ v,\ \phi)$ is used, whereas Arfken (1970) uses $(\xi,\ \eta,\ \varphi)$ and Moon and Spencer (1988) use $(\eta,\ \theta,\ \psi)$. The toroidal coordinates are defined by

$$x = \frac{a \sinh u \cos \phi}{\cosh u - \cos v} \tag{1}$$

$$y = \frac{a \sinh u \sin \phi}{\cosh u - \cos v} \tag{2}$$

$$z = \frac{a \sin v}{\cosh u - \cos v}, \tag{3}$$

where $\sinh z$ is the hyperbolic sine and $\cosh z$ is the hyperbolic cosine. Surfaces of constant u are given by the toroids

$$x^2 + y^2 + z^2 + a^2 = 2a\sqrt{x^2 + y^2} \coth u, \tag{4}$$

surfaces of constant v by the spherical bowls

$$x^2 + y^2 + (z - a \cot v)^2 = \frac{a^2}{\sin^2 v}, \tag{5}$$

and surfaces of constant ϕ by

$$\tan \phi = \frac{y}{x}. \tag{6}$$

The SCALE FACTORS are

$$h_u = \frac{a}{\cosh u - \cos v} \tag{7}$$

$$h_v = \frac{a}{\cosh u - \cos v} \tag{8}$$

$$h_\phi = \frac{a \sinh u}{\cosh u - \cos v}. \tag{9}$$

The LAPLACIAN is

$$\nabla^2 f = \frac{\sinh u}{(\cosh u - \cos v)^3} \left[\frac{\partial}{\partial u} \left(\frac{\sinh u}{\cosh u - \cos v} \frac{\partial f}{\partial u} \right) + \frac{\partial}{\partial v} \left(\frac{\sinh u}{\cosh u - \cos v} \frac{\partial f}{\partial v} \right) + \frac{\partial}{\partial \phi} \times \left(\frac{\operatorname{csch} u}{\cosh u - \cos v} \frac{\partial f}{\partial \phi} \right) \right] \tag{10}$$

$$= (\cos v - \cosh u) \times \left[\sin v \frac{\partial f}{\partial v} + (\cos v - \cosh u) \times \left(\operatorname{csch}^2 u \frac{\partial^2 f}{\partial \phi^2} + \frac{\partial^2 f}{\partial v^2} \right) \right] + (\cos v \cosh u - 1) \operatorname{csch} u \frac{\partial f}{\partial u} + (\cos v - \cosh u) \frac{\partial^2 f}{\partial u^2} \Bigg]. \tag{11}$$

The HELMHOLTZ DIFFERENTIAL EQUATION is not separable in toroidal coordinates, but LAPLACE'S EQUATION is.

Toroidal Crossing Number

The first few toroidal crossing numbers for a COMPLETE GRAPH are 0, 0, 0, 0, 0, 0, 0, 4, 9, 23, 42, 70, 105, 154, 226, 326, ... (Sloane's A014543). The toroidal crossing numbers for a COMPLETE BIGRAPH are given in the following table.

1	0	0	0	0	0	0
2		0	0	0	0	0
3			0	0	0	0
4					2	
5					5	8
6						12
7

Toroidal Field

A VECTOR FIELD resembling a TORUS which is purely circular about the z-AXIS of a SPHERE (i.e., follows lines of LATITUDE). A toroidal field takes the form

$$\mathbf{T} = \begin{bmatrix} 0 \\ \dfrac{1}{\sin \theta} \dfrac{\partial T}{\partial \phi} \\ -\dfrac{\partial T}{\partial \theta} \end{bmatrix}.$$

Toroidal Function

A class of functions also called RING FUNCTIONS which appear in systems having toroidal symmetry. Toroidal functions can be expressed in terms of the LEGENDRE FUNCTIONS and SECOND KINDS (Abramowitz and Stegun 1972, p. 336):

$$P^{\mu}_{\nu-1/2}(\cosh\eta) = [\Gamma(1-\mu)]^{-1}2^{2\mu}\left(1-e^{-2\eta}\right)^{-\mu}e^{-(\nu+1/2)\eta}$$
$$\times {}_2F_1\left(\tfrac{1}{2}-\mu,\ \tfrac{1}{2}+\nu-\mu;\ 1-2\mu;\ 1-e^{-2\eta}\right)$$

$$P^{m}_{n-1/2}(\cosh\eta) = \frac{\Gamma\left(n+m+\frac{1}{2}\right)(\sinh\eta)^m}{\Gamma\left(n-m+\frac{1}{2}\right)2^m\sqrt{\pi}\,\Gamma\left(m+\frac{1}{2}\right)}$$
$$\times\int_0^{\pi}\frac{\sin^{2m}\phi\,d\phi}{(\cosh\eta+\cos\phi\sinh\eta)^{n+m+1/2}}$$

$$Q^{\mu}_{\nu-1/2}(\cosh\eta) = [\Gamma(1+\nu)]^{-1}\sqrt{\pi}\,e^{i\mu\pi}\Gamma\left(\tfrac{1}{2}+\nu+\mu\right)$$
$$\times\left(1-e^{-2\eta}\right)^{\mu}e^{-(\nu+1/2)\eta}{}_2F_1$$
$$\times\left(\tfrac{1}{2}-\mu,\ \tfrac{1}{2}+\nu+\mu;\ 1+\mu;\ 1-e^{-2\eta}\right)$$

$$Q^{m}_{n-1/2}(\cosh\eta) = \frac{(-1)^m\Gamma\left(n+\frac{1}{2}\right)}{\Gamma\left(n-m+\frac{1}{2}\right)}$$
$$\times\int_0^{\infty}\frac{\cosh(mt)\,dt}{(\cosh\eta+\cosh t\sinh\eta)^{n+1/2}}$$

for $n > m$. Byerly (1959) identifies

$$\frac{1}{i^{n/2}}P^n_m(\coth x) = \operatorname{csch}^n x\,\frac{d^nP_m(\coth x)}{d(\coth x)^n}$$

as a TOROIDAL HARMONIC.

Toroidal Harmonic

TOROIDAL FUNCTION

Toroidal Polyhedron

A toroidal polyhedron is a POLYHEDRON with GENUS $g \geq 1$ (i.e., having one or more HOLES). Examples of toroidal polyhedra include the CSÁSZÁR POLYHEDRON and SZILASSI POLYHEDRON, both of which have GENUS 1 (i.e., the TOPOLOGY of a TORUS).

The only known TOROIDAL POLYHEDRON with no DIAGONALS is the CSÁSZÁR POLYHEDRON. If another exists, it must have 12 or more VERTICES and GENUS $g \geq 6$ (Gardner 1975). The smallest known single-hole toroidal polyhedron made up of only EQUILATERAL TRIANGLES is composed of 48 of them.

Toronto Function

The function defined by

$$T(m,\ n,\ r) \equiv r^{2n-m+1}e^{-r^2}\ \frac{\Gamma\left(\frac{1}{2}m+\frac{1}{2}\right)}{n!}$$
$$\times {}_1F_1\left(\tfrac{1}{2}(m+1);\ n+1;\ r^2\right) \quad (1)$$

(Heatley 1943; Abramowitz and Stegun 1972, p. 509), where ${}_1F_1(a;\ b;\ z)$ is a CONFLUENT HYPERGEOMETRIC FUNCTION and $\Gamma(z)$ is the GAMMA FUNCTION.

Heatley originally defined the function in terms of the integral

$$T(m,\ n,\ p,\ a) = \int_0^{\infty}t^{-n}e^{-p^2t^2}I_n(2at)\,dt, \quad (2)$$

where $I_n(x)$ is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND, which is similar to an integral of Watson (1966, p. 394), with Watson's $J_\nu(at)$ changed to $I_n(2at)$ and a few other minor changes of variables. In terms of this function,

$$T(m,\ n,\ r) = 2r^{n-m+1}e^{-r^2}T(m,\ n,\ 1,\ r) \quad (3)$$

(Heatley 1943). Heatley (1943) also gives a number of recurrences and other identities satisfied by $T(m,\ n,\ r)$.

Torricelli Point

FERMAT POINTS

Torsion (Differential Geometry)

The rate of change of the OSCULATING PLANE of a SPACE CURVE. The torsion τ is POSITIVE for a right-handed curve, and NEGATIVE for a left-handed curve. A curve with CURVATURE $\kappa \neq 0$ is planar IFF $\tau = 0$.

The torsion can be defined by

$$\tau \equiv -\mathbf{N} \cdot \mathbf{B}',$$

where $\mathbf{N}$ is the unit NORMAL VECTOR and $\mathbf{B}$ is the unit BINORMAL VECTOR. Written explicitly in terms of a parameterized VECTOR FUNCTION $\mathbf{x}$,

$$\tau = \frac{|\dot{\mathbf{x}}\ddot{\mathbf{x}}\dddot{\mathbf{x}}|}{\ddot{\mathbf{x}} \cdot \ddot{\mathbf{x}}} = \rho^2 |\dot{\mathbf{x}}\ddot{\mathbf{x}}\dddot{\mathbf{x}}|,$$

where $|\mathbf{abc}|$ denotes a SCALAR TRIPLE PRODUCT and ρ is the RADIUS OF CURVATURE. The quantity $1/\tau$ is called the RADIUS OF TORSION and is denoted σ or ϕ.

See also CURVATURE, RADIUS OF CURVATURE, RADIUS OF TORSION

Torsion (Group)

If G is a GROUP, then the torsion elements Tor(G) of G (also called the torsion of G) are defined to be the set of elements g in G such that $g^n = e$ for some NATURAL NUMBER n, where e is the IDENTITY ELEMENT of the GROUP G.

In the case that G is ABELIAN, Tor(G) is a SUBGROUP and is called the torsion subgroup of G. If Tor(G) consists only of the IDENTITY ELEMENT, the GROUP G is called torsion-free.

See also ABELIAN GROUP, FREE ABELIAN GROUP, GROUP, IDENTITY ELEMENT

Torsion Number

One of a set of numbers defined in terms of an invariant generated by the finite cyclic covering spaces of a KNOT complement. The torsion numbers for KNOTS up to 9 crossings were cataloged by Reidemeister (1948).

See also KNOT INVARIANT

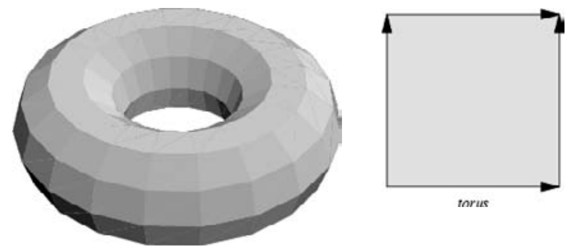
TORSION (GROUP)

Torsion Tensor



The TENSOR defined by

$$T^l{}_{jk} \equiv -(\Gamma^l{}_{jk} - \Gamma^l{}_{kj}),$$

where $\Gamma^l{}_{jk}$ are CONNECTION COEFFICIENTS.

See also CONNECTION COEFFICIENT

Torus

A torus is a surface having GENUS 1, and therefore possessing a single "HOLE." The usual torus in 3-D space is shaped like a donut, but the concept of the torus is extremely useful in higher dimensional space as well. One of the more common uses of n-D tori is in DYNAMICAL SYSTEMS. A fundamental result states that the PHASE SPACE trajectories of a HAMILTONIAN SYSTEM with n DEGREES OF FREEDOM and possessing n INTEGRALS OF MOTION lie on an n-D MANIFOLD which is topologically equivalent to an n-torus (Tabor 1989).

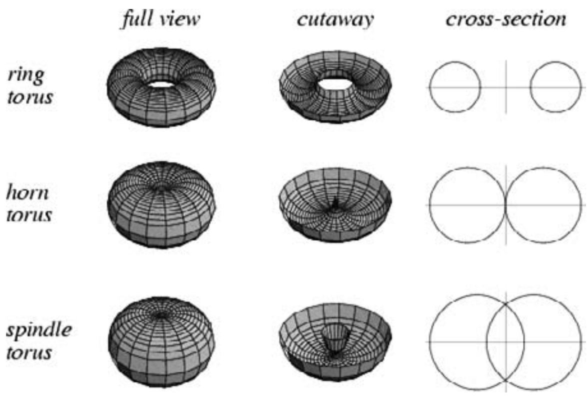
The usual 3-D "ring" torus is known in older literature as an "ANCHOR RING." It can be constructed from a RECTANGLE by gluing both pairs of opposite edges together with no twists.

Let the radius from the center of the hole to the center of the torus tube be c, and the radius of the tube be a. Then the equation in CARTESIAN COORDINATES for a torus azimuthally symmetric about the z-AXIS is

$$\left(c - \sqrt{x^2 + y^2}\right)^2 + z^2 = a^2, \tag{1}$$

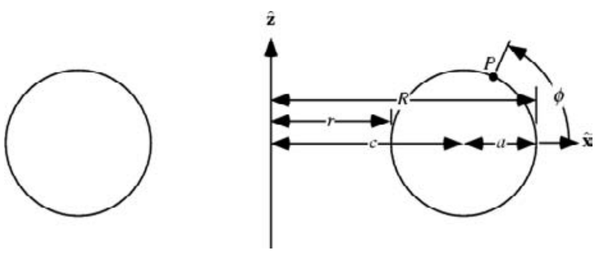
and the PARAMETRIC EQUATIONS are

$$x = (c + a \cos v) \cos u \tag{2}$$



$$y = (c + a \cos u) \sin u \tag{3}$$

$$z = a \sin v \tag{4}$$



for $u,\ v \in [0,\ 2\pi)$. Three types of torus, known as the STANDARD TORI, are possible, depending on the relative sizes of a and c. $c > a$ corresponds to the

RING TORUS (shown above), $c=a$ corresponds to a HORN TORUS which is tangent to itself at the point (0, 0, 0), and $c<a$ corresponds to a self-intersecting SPINDLE TORUS (Pinkall 1986).

If no specification is made, "torus" is taken to mean RING TORUS. The three STANDARD TORI are illustrated below, where the first image shows the full torus, the second a cut-away of the bottom half, and the third a CROSS SECTION of a plane passing through the z-AXIS.

The STANDARD TORI and their inversions are CYCLIDES. If the coefficient of $\sin v$ in the formula for z is changed to $b \neq a$, an ELLIPTIC TORUS results.

To compute the metric properties of the ring torus, define the inner and outer radii by

$$r \equiv c-a \tag{5}$$

$$R \equiv c+a. \tag{6}$$

Solving for a and c gives

$$a=\tfrac{1}{2}(R-r) \tag{7}$$

$$c=\tfrac{1}{2}(R+r). \tag{8}$$

Then the SURFACE AREA of this torus is

$$S=(2\pi a)(2\pi c)=4\pi^2 ac \tag{9}$$

$$=\pi^2(R+r)(R-r), \tag{10}$$

and the VOLUME can be computed from PAPPUS'S CENTROID THEOREM

$$V=\left(\pi a^2\right)(2\pi c)=2\pi^2 a^2 c \tag{11}$$

$$=\tfrac{1}{4}\pi^2(R+r)(R-r)^2. \tag{12}$$

The coefficients of the coefficients of the FIRST FUNDAMENTAL FORM are

$$E=(c+a\cos v)^2 \tag{13}$$

$$F=0 \tag{14}$$

$$G=a^2 \tag{15}$$

and the coefficients of the SECOND FUNDAMENTAL FORM are

$$e=-(c+a\cos v)\cos v \tag{16}$$

$$f=0 \tag{17}$$

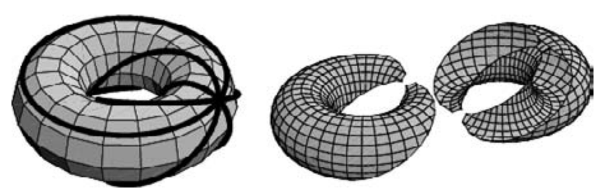
$$g=-a, \tag{18}$$

giving RIEMANNIAN METRIC

$$ds^2=(c+a\cos v)^2\,du^2+a^2\,dv^2, \tag{19}$$

AREA ELEMENT

$$dA=a(c+a\cos v)\,du\wedge dv \tag{20}$$



(where $du\wedge dv$ is a WEDGE PRODUCT), and GAUSSIAN and MEAN CURVATURES as

$$K=\frac{\cos v}{a(c+a\cos v)} \tag{21}$$

$$H=-\frac{c+2a\cos v}{2a(c+a\cos v)} \tag{22}$$

(Gray 1997, pp. 384–386).

A torus with a HOLE in *its surface* can be turned inside out to yield an identical torus. A torus can be knotted externally or internally, but not both. These two cases are AMBIENT ISOTOPIES, but not REGULAR ISOTOPIES. There are therefore three possible ways of embedding a torus with zero or one KNOT.

An arbitrary point P on a torus (not lying in the xy-plane) can have four CIRCLES drawn through it. The first circle is in the plane of the torus and the second is PERPENDICULAR to it. The third and fourth CIRCLES are called VILLARCEAU CIRCLES (Villarceau 1848, Schmidt 1950, Coxeter 1969, Melnick 1983).

To see that two additional CIRCLES exist, consider a coordinate system with origin at the center of torus, with $\hat{\mathbf{z}}$ pointing up. Specify the position of P by its ANGLE ϕ measured around the tube of the torus. Define $\phi=0$ for the circle of points farthest away

from the center of the torus (i.e., the points with $x^2 + y^2 = R^2$), and draw the X-AXIS as the intersection of a plane through the Z-AXIS and passing through P with the xy-plane. Rotate about the Y-AXIS by an ANGLE θ, where

$$\theta = \sin^{-1}\left(\frac{a}{c}\right). \tag{23}$$

In terms of the old coordinates, the new coordinates are

$$x = x_1 \cos\theta - z_1 \sin\theta \tag{24}$$

$$z = x_1 \sin\theta + z_1 \cos\theta. \tag{25}$$

So in (x_1, y_1, z_1) coordinates, equation (1) of the torus becomes

$$\left[\sqrt{(x_1 \cos\theta - z_1 \sin\theta)^2 + y_1^2} - c\right]^2$$

$$+(x_1 \sin\theta + z_1 \cos\theta)^2 = a^2. \tag{26}$$

Expanding the left side gives

$$(x_1 \cos\theta - z_1 \sin\theta)^2 + y_1^2 + c^2$$

$$-2c\sqrt{(x_1 \cos\theta - z_1 \sin\theta)^2 + y_1^2}$$

$$+(x_1 \sin\theta + z_1 \cos\theta)^2 = a^2. \tag{27}$$

But

$$(x_1 \cos\theta - z_1 \sin\theta)^2 + (x_1 \sin\theta + z_1 \cos\theta)^2$$
$$= x_1^2 + z_1^2, \tag{28}$$

so

$$x_1^2 + y_1^2 + z_1^2 + c^2 - 2c\sqrt{(x_1 \cos\theta - z_1 \sin\theta)^2 + y_1^2}$$
$$= a^2. \tag{29}$$

In the $z_1 = 0$ plane, plugging in (23) and factoring gives

$$\left[x_1^2 + (y_1 - a)^2 - c^2\right]\left[x_1^2 + (y_1 + a)^2 - c^2\right] = 0. \tag{30}$$

This gives the CIRCLES

$$x_1^2 + (y_1 - a)^2 = c^2 \tag{31}$$

and

$$x_1^2 + (y_1 + a)^2 = c^2 \tag{32}$$

in the z_1 plane. Written in MATRIX form with parameter $t \in [0, 2\pi)$, these are

$$C_1 = \begin{bmatrix} c\cos t \\ c\sin t + a \\ 0 \end{bmatrix} \tag{33}$$

$$C_2 = \begin{bmatrix} c\cos t \\ c\sin t - a \\ 0 \end{bmatrix} \tag{34}$$

In the original (x, y, z) coordinates,

$$C_1 = \begin{bmatrix} \cos\theta & 0 & -\sin\theta \\ 0 & 1 & 0 \\ -\sin\theta & 0 & \cos\theta \end{bmatrix} \begin{bmatrix} c\cos t \\ c\sin t + a \\ 0 \end{bmatrix}$$

$$= \begin{bmatrix} c\cos\theta\cos t \\ c\sin t + a \\ -c\sin\theta\cos t \end{bmatrix} \tag{35}$$

$$C_2 = \begin{bmatrix} \cos\theta & 0 & \sin\theta \\ 0 & 1 & 0 \\ -\sin\theta & 0 & \cos\theta \end{bmatrix} \begin{bmatrix} c\cos t \\ c\sin t - a \\ 0 \end{bmatrix}$$

$$= \begin{bmatrix} c\cos\theta\cos t \\ c\sin t - a \\ -c\sin\theta\cos t \end{bmatrix}. \tag{36}$$

The point P must satisfy

$$z = a\sin\phi = c\sin\theta\cos t, \tag{37}$$

so

$$\cos t = \frac{a\sin\phi}{c\sin\theta}. \tag{38}$$

Plugging this in for x_1 and y_1 gives the ANGLE ψ by which the CIRCLE must be rotated about the Z-AXIS in order to make it pass through P,

$$\psi = \tan^{-1}\left(\frac{y}{x}\right) = \frac{c\sin t + a}{c\cos\theta\cos t} = \frac{c\sqrt{1 - \cos^2 t} + a}{c\cos\theta\cos t}. \tag{39}$$

The four CIRCLES passing through P are therefore

$$C_1 = \begin{bmatrix} \cos\psi & \sin\psi & 0 \\ -\sin\psi & \cos\psi & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} c\cos\theta\cos t \\ c\sin t + a \\ -c\sin\theta\cos t \end{bmatrix} \tag{40}$$

$$C_2 = \begin{bmatrix} \cos\psi & \sin\psi & 0 \\ -\sin\psi & \cos\psi & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} c\cos\theta\cos t \\ c\sin t - a \\ -c\sin\theta\cos t \end{bmatrix} \tag{41}$$

$$C_3 = \begin{bmatrix} (c + a\cos\phi)\cos t \\ (c + a\cos\phi)\sin t \\ a\sin\phi \end{bmatrix} \tag{42}$$

$$C_4 = \begin{bmatrix} c + a\cos t \\ 0 \\ a\sin t \end{bmatrix}. \tag{43}$$

Torus Coloring

The number of colors SUFFICIENT for MAP COLORING on a surface of GENUS g is given by the HEAWOOD CONJECTURE,

$$\chi(g) = \left\lfloor \tfrac{1}{2}\left(7 + \sqrt{48g + 1}\right) \right\rfloor,$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION. The fact that $\chi(g)$ (which is called the CHROMATIC NUMBER) is also NECESSARY was proved by Ringel and Youngs (1968) with two exceptions: the SPHERE (which requires the same number of colors as the PLANE) and the KLEIN BOTTLE. A g-holed TORUS therefore requires $\chi(g)$ colors. For $g = 0$, 1, ..., the first few values of $\chi(g)$ are 4, 7, 8, 9, 10, 11, 12, 12, 13, 13, 14, 15, 15, 16, ... (Sloane's A000934). A set of regions requiring the maximum of seven regions is shown above for a normal TORUS

Heawood graph *torus coloring*

The above figure shows the relationship between the HEAWOOD GRAPH and the 7-color torus coloring.

Torus Cutting

With n cuts of a TORUS of GENUS 1, the maximum number of pieces which can be obtained is

$$N(n) = \tfrac{1}{6}(n^3 + 3n^3 + 8n).$$

The first few terms are 2, 6, 13, 24, 40, 62, 91, 128, 174, 230, ... (Sloane's A003600).

Torus Dissection

A ring TORUS constructed out of a square of side length c can be dissected into two squares of arbitrary side lengths a and b (as long as they are consistent with the size of the original square), as illustrated above.

See also DISSECTION, TORUS

References

Stewart, I. "Squaring the Square." *Sci. Amer.* **277**, 94–96, July 1997.

Torus Knot

A (p, q)-torus KNOT is obtained by looping a string through the HOLE of a TORUS p times with q revolutions before joining its ends, where p and q are RELATIVELY PRIME. A (p, q)-torus knot is equivalent to a (q, p)-torus knot. All torus knots are PRIME (Burde and Zieschang 1985, Hoste *et al.* 1998). Torus knots are all chiral, invertible, and have symmetry group D_1 (Schreier 1924, Hoste *et al.* 1998).

The CROSSING NUMBER of a (p, q)-torus knot is

$$c = \min\{p(q-1),\ q(p-1)\} \tag{1}$$

(Williams 1988, Murasugi and Przytycki 1989, Murasugi 1991, Hoste *et al.* 1998). The UNKNOTTING NUMBER of a (p, q)-torus knot is

$$u = \tfrac{1}{2}(p-1)(q-1) \tag{2}$$

(Adams 1991).

Torus knots with fewer than 11 crossings are the TREFOIL KNOT 03–001 (3, 2), SOLOMON'S SEAL KNOT 05–001 (5, 2), 07–001 (7, 2), 08–019 (4, 3), 09–001 (9, 2), and 10–124 (5, 3) (Adams *et al.* 1991). The torus knots with 16 or fewer crossings are (3, 2), (5, 2), (7, 2), (9, 2), (11, 2), (13, 2), (15, 2), (4, 3), (5, 3), (7, 3), (8, 3), and (5, 4) (Hoste *et al.* 1998). The numbers of torus knots with n crossings are 0, 0, 1, 0, 1, 0, 1, 1, 1, 1, 1, 0, 1, 1, 2, 1, ... (Sloane's A051764).

The only KNOTS which are not HYPERBOLIC KNOTS are torus knots and SATELLITE KNOTS (including COMPOSITE KNOTS). The $(q, 2)$, $(4, 3)$, and $(5, 4)$-torus knots are ALMOST ALTERNATING KNOTS (Adams 1994, p. 142).

The JONES POLYNOMIAL of an (m, n)-TORUS KNOT is

$$\frac{t^{(m-1)(n-1)/2}(1 - t^{m+1} - t^{n+1} + t^{m+n})}{1 - t^2}. \tag{3}$$

The BRACKET POLYNOMIAL for the torus knot $K_n = (2, n)$ is given by the RECURRENCE RELATION

$$\langle K_n \rangle = A\langle K_{n-1}\rangle + (-1)^{n-1}A^{-3n+2}, \tag{4}$$

where

$$\langle K_1 \rangle = -A^3. \tag{5}$$

Total Variation Measure
Given a COMPLEX MEASURE μ, there exists a POSITIVE MEASURE denoted $|\mu|$ which measures the total variation of μ, also sometimes called simply "total variation." In particular, $|\mu|(E)$ on a SUBSET E is the largest sum of "variations" for any subdivision of E. Roughly speaking, a total variation measure is an infinitesimal version of the ABSOLUTE VALUE.

More precisely,

$$|\mu|(E)=\sup\sum_i|\mu(E_i)| \tag{1}$$

where the SUPREMUM is taken over all partitions $\cup E_i$ of E into MEASURABLE SUBSETS E_i.

Note that $|\mu(X)|$ may not be the same as $|\mu|(X)$. When μ already is a POSITIVE MEASURE, then $\mu=|\mu|$. More generally, if μ is ABSOLUTELY CONTINUOUS, that is

$$\mu(E)=\int_E f\,dx, \tag{2}$$

then so is $|\mu|$, and the total variation measure can be written as

$$|\mu|(E)=\int_E |f|\,dx. \tag{3}$$

The total variation measure can be used to rewrite the original measure, in analogy to the norm of a COMPLEX NUMBER. The measure μ has a POLAR REPRESENTATION

$$d\mu=h\,d|\mu| \tag{4}$$

with $|h|=1$.

Totalistic Cellular Automaton
A totalistic cellular automaton is a 1-D cellular automata in which the rules depend only on the total of the values of the cells in a neighborhood. These automata were introduced by Stephen Wolfram in 1983.

See also CELLULAR AUTOMATON

Totally Ordered Set

A total order (or "totally ordered set," or "linearly ordered set") is a SET plus a relation on the set (called a TOTAL ORDER) that satisfies the conditions for a PARTIAL ORDER plus an additional condition known as the comparability condition. A RELATION $\leq$ is a partial order on a SET S (if the following properties hold.

1. Reflexivity: $a \leq a$ for all $a \in S$.
2. Weak antisymmetry: $a \leq b$ and $b \leq a$ implies $a = b$.
3. Transitivity: $a \leq b$ and $b \leq c$ implies $a \leq c$.
4. Comparability (TRICHOTOMY LAW): For any a, $b \in S$, either $a \leq b$ or $b \leq a$.

The first three are the axioms of a PARTIAL ORDER, while addition of the TRICHOTOMY LAW defines a total order.

Every finite totally ordered set is WELL ORDERED. Any two totally ordered sets with k elements (for k a nonnegative integer) are ORDER ISOMORPHIC, and therefore have the same ORDER TYPE (which is also an ORDINAL NUMBER).

Totative

A POSITIVE INTEGER less than or equal to a number n which is also RELATIVELY PRIME to n, where 1 is counted as being RELATIVELY PRIME to all numbers. The number of totatives of n is the value of the TOTIENT FUNCTION $\phi(n)$.

See also RELATIVELY PRIME, TOTIENT FUNCTION

Totient Function

The totient function $\phi(n)$, also called Euler's totient function, is defined as the number of POSITIVE INTEGERS $\leq n$ which are RELATIVELY PRIME to (i.e., do not contain any factor in common with) n, where 1 is counted as being RELATIVELY PRIME to all numbers. Since a number less than or equal to and RELATIVELY PRIME to a given number is called a TOTATIVE, the totient function $\phi(n)$ can be simply defined as the number of TOTATIVES of n. For example, there are eight TOTATIVES of 24 (1, 5, 7, 11, 13, 17, 19, and 23), so $\phi(24) = 8$.

$\phi(n)$ is always EVEN for $n \geq 3$. By convention, $\phi(0) = 1$, although *Mathematica* defines `EulerPhi[0]` equal to 0 for consistency with its `FactorInteger[0]` command. The first few values of $\phi(n)$ for $n = 1, 2, \ldots$ are 1, 1, 2, 2, 4, 2, 6, 4, 6, 4, 10, ... (Sloane's A000010). The totient function is given by the MÖBIUS TRANSFORM of 1, 2, 3, 4, ... (Sloane and Plouffe 1995, p. 22). $\phi(n)$ is plotted above for small n.

For a PRIME p,

$$\phi(p) = p - 1, \tag{1}$$

since all numbers less than p are RELATIVELY PRIME to p. If $m = p^\alpha$ is a POWER of a PRIME, then the numbers which have a common factor with m are the multiples of p: p, $2p$, ..., $(p^{\alpha-1})p$. There are $p^{\alpha-1}$ of these multiples, so the number of factors RELATIVELY PRIME to p^α is

$$\phi(p^\alpha) = p^\alpha - p^{\alpha-1} = p^{\alpha-1}(p-1) = p^\alpha\left(1 - \frac{1}{p}\right). \tag{2}$$

Now take a general m divisible by p. Let $\phi_p(m)$ be the number of POSITIVE INTEGERS $\leq m$ not DIVISIBLE by p. As before, p, $2p$, ..., $(m/p)p$ have common factors, so

$$\phi_p(m) = m - \frac{m}{p} = m\left(1 - \frac{1}{p}\right). \tag{3}$$

Now let q be some other PRIME dividing m. The INTEGERS divisible by q are q, $2q$, ..., $(m/q)q$. But these duplicate pq, $2pq$, ..., $(m/pq)pq$. So the number of terms which must be subtracted from ϕ_p to obtain ϕ_{pq} is

$$\Delta\phi_p(m) = \frac{m}{q} - \frac{m}{pq} = \frac{m}{q}\left(1 - \frac{1}{p}\right), \tag{4}$$

and

$$\phi_{pq}(m) \equiv \phi_p(m) - \Delta\phi_q(m)$$
$$= m\left(1-\frac{1}{p}\right) - \frac{m}{p}\left(1-\frac{1}{p}\right)$$
$$= m\left(1-\frac{1}{p}\right)\left(1-\frac{1}{q}\right). \quad (5)$$

By induction, the general case is then

$$\phi(n) = n\left(1-\frac{1}{p_1}\right)\left(1-\frac{1}{p_2}\right)\cdots\left(1-\frac{1}{p_r}\right). \quad (6)$$

An interesting identity relates $\phi(n^2)$ to $\phi(n)$,

$$\phi(n^2) = n\phi(n). \quad (7)$$

Another identity relates the DIVISORS d of n to n via

$$\sum_d \phi(d) = n. \quad (8)$$

The DIVISOR FUNCTION satisfies the CONGRUENCE

$$n\sigma(n) \equiv 2 \pmod{\phi(n)}$$
$$= \begin{cases} n\sigma(n) \equiv 0 \pmod{\phi(n)} & \text{if } \phi(n) = 2 \\ n\sigma(n) \equiv 2 \pmod{\phi(n)} & \text{otherwise} \end{cases} \quad (9)$$

for all PRIMES $p \geq 5$ and no COMPOSITE with the exception of 4, 6, and 22, where $\sigma(n)$ is the DIVISOR FUNCTION. This fact was proved by Subbarao (1974), despite the implication to the contrary, "is it true for infinitely many composite n?," stated in Guy (1994, p. 92). No COMPOSITE solution is currently known to

$$n - 1 \equiv 0 \pmod{\phi(n)} \quad (10)$$

(Honsberger 1976, p. 35).

If the GOLDBACH CONJECTURE is true, then for every number m, there are PRIMES p and q such that

$$\phi(p) + \phi(q) = 2m \quad (11)$$

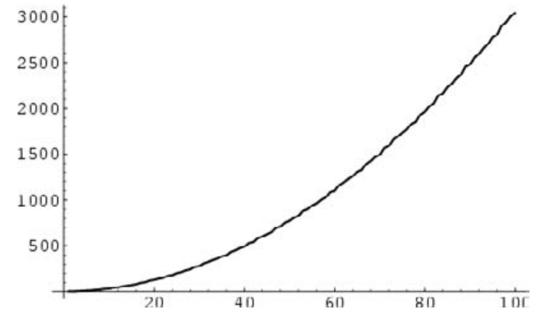
(Guy 1994, p. 105). Guy (1994, p. 99) discussed solutions to

$$\phi(\sigma(n)) = n, \quad (12)$$

where $\sigma(n)$ is the DIVISOR FUNCTION. F. Helenius has found 365 such solutions, the first of which are 2, 8, 12, 128, 240, 720, 6912, 32768, 142560, 712800, ... (Sloane's A001229).

Curious equalities of consecutive values include

$$\phi(5186) = \phi(5187) = \phi(5188) = 2^5 3^4 \quad (13)$$



$$\phi(25930) = \phi(25935) = \phi(25942) = 2^7 3^4 \quad (14)$$

$$\phi(404471) = \phi(404473) = \phi(404477) = 2^8 3^2 5^2 7 \quad (15)$$

(Guy 1994, p. 91). McCranie found an arithmetic progression of six numbers with equal totient functions,

$$\phi(583200) = \phi(583230) = \phi(583260) = \phi(583290)$$
$$= \phi(583320) = \phi(583350) = 155520, \quad (16)$$

as well as other progressions of six numbers starting at 583200, 1166400, 1749600, ... (Sloane's A050518).

The SUMMATORY totient function, plotted above, is defined by

$$\Phi(n) \equiv \sum_{k=1}^{n} \phi(k). \quad (17)$$

The first values of $\Phi(n)$ are 1, 2, 4, 6, 10, 12, 18, 22, 28, ... (Sloane's A002088). $\Phi(n)$ has the asymptotic series

$$\Phi(x) \sim \frac{1}{2\zeta(2)} x^2 + \mathcal{O}(x \ln x) \quad (18)$$

$$\sim \frac{3}{\pi^2} x^2 + \mathcal{O}(x \ln x), \quad (19)$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION (Perrot 1881; Nagell 1951, p. 131). An improved asymptotic estimate due to Walfisz (1963) is given by

$$\sum_{n=1}^{N} \phi(n) = \frac{3N^2}{\pi^2} + \mathcal{O}\left[N(\ln N)^{2/3}(\ln \ln N)^{4/3}\right]. \quad (20)$$

Landau (1900, quoted in Dickson 1952) showed that the asymptotic series of the summatory function of $1/\phi(n)$ is

$$\sum_{n=1}^{N} \frac{1}{\phi(n)} = A \ln N + B + \mathcal{O}\left(\frac{\ln N}{N}\right), \quad (21)$$

where

$$A = \sum_{k=1}^{\infty} \frac{[\mu(k)]^2}{k\phi(k)} = \frac{\zeta(2)\zeta(3)}{\zeta(6)} = \frac{315}{2\pi^4}\zeta(3)$$
$$= 1.9435964368\ldots \quad (22)$$

$$B = \gamma \frac{315}{2\pi^4}\zeta(3) - \sum_{k=1}^{\infty} \frac{[\mu(k)]^2 \ln k}{k\phi(k)}$$
$$= -0.0595536246\ldots, \quad (23)$$

$\mu(k)$ is the MÖBIUS FUNCTION, $\zeta(z)$ is the RIEMANN ZETA FUNCTION, and γ is the EULER-MASCHERONI CONSTANT (Dickson). A can also be written

$$A = \prod_{k=1}^{\infty} \frac{1 - p_k^6}{(1 - p_k^{-2})(1 - p_k^{-3})} = \prod_{k=1}^{\infty} \left[1 + \frac{1}{p_k(p_k - 1)}\right]. \quad (24)$$

Note that this constant is similar to ARTIN'S CONSTANT.

Totient Function Constants

SILVERMAN CONSTANT, TOTIENT FUNCTION

Totient Valence Function

$N_\phi(m)$ is the number of INTEGERS n for which the TOTIENT FUNCTION $\phi(n)=m$, also called the MULTIPLICITY of m (Guy 1994). Erdos(1958) proved that is a multiplicity occurs once, it occurs infinitely often. The table below lists values for $\phi(N) \le 50$.

$\phi(N)$	multiplicity	N
1	2	1, 2
2	3	3, 4, 6
4	4	5, 8, 10, 12
6	4	7, 9, 14, 18
8	5	15, 16, 20, 24, 30
10	2	11, 22
12	6	13, 21, 26, 28, 36, 42
16	6	17, 32, 34, 40, 48, 60
18	4	19, 27, 38, 54

It is thought that $N_\phi(m) \geq 2$ (i.e., the totient valence function never takes on the value 1), but this has not been proven. This assertion is called CARMICHAEL'S TOTIENT FUNCTION CONJECTURE and is equivalent to the statement that for all n, there exists $m \neq n$ such that $\phi(n) = \phi(m)$ (Ribenboim 1996, pp. 39–40). Any counterexample must have more than 10,000,000 DIGITS (Schlafly and Wagon 1994, erroneously given as 10,000 in Conway and Guy 1996).

Tour

A sequence of moves on a chessboard by a CHESS piece in which each square of a CHESSBOARD is visited exactly once.

See also CHESS, HAMILTONIAN CIRCUIT, KNIGHT'S TOUR, MAGIC TOUR, TRAVELING SALESMAN CONSTANTS

Tournament

A COMPLETE DIRECTED GRAPH (Skiena 1990, p. 175). A so-called SCORE SEQUENCE can be associated with every tournament. The number of nonisomorphic tournaments on 2, 3, 4, ... nodes are 1, 2, 4, ..., illustrated above. The first and second 3-node tournaments shown above are called a TRANSITIVE TRIPLE and CYCLIC TRIPLE, respectively (Harary 1994, p. 204).

Every tournament contains an odd number of HAMILTONIAN PATHS (Rédei 1934; Szele 1943; Skiena 1990, p. 175). However, a tournament has a directed HAMILTONIAN CIRCUIT IFF it is STRONGLY CONNECTED (Foulkes 1960; Harary and Moser 1966; Skiena 1990, p. 175).

The term "tournament" also refers to an arrangement by which teams or players play against certain other teams or players in order to determine who is the best. In a "cup" tournament of $n-2^k$ teams, teams play pairwise in a sequence of $1/2^{k-1}$-finals, ..., 1/8-finals, quarter-finals, semi-finals, and finals, with winners from each round playing other winners in the next round and losers being eliminated at each round. The second-place prize is usually awarded to the team which loses in the finals. However, this practice is unfair since the second-place team has not been required to play against the teams which were eliminated by the first-place (and presumably best) team, and therefore might actually be worse than one of the teams eliminated earlier by the best team (Steinhaus 1983).

In general, to fairly determine the best two players from n contestants, $n-1+\log_2(n-1)$ rounds are required (Steinhaus 1983, p. 55).

Tournament Matrix

A matrix for a round-robin tournament involving n players competing in $n(n-1)/2$ matches (no ties allowed) having entries

$$a_{ij} = \begin{cases} 1 & \text{if player } i \text{ defeats player } j \\ -1 & \text{if player } i \text{ loses to player } j. \\ 0 & \text{if } i = j \end{cases}$$

The matrix satisfies

$$\mathsf{A} + \mathsf{A}^{\mathrm{T}} + \mathsf{I} = \mathsf{J},$$

where I is the identity matrix, J is an $n \times n$ matrix of all 1s, and A^{T} is the matrix transpose of A.

The tournament matrix for n players has zero determinant iff n is odd (McCarthy and Benjamin 1996). The dimension of the nullspace of an n-player tournament matrix is

$$\dim[\text{nullspace}] = \begin{cases} 0 & \text{for } n \text{ even} \\ 1 & \text{for } n \text{ odd} \end{cases}$$

(McCarthy 1996).

Tournament Sequence

A tournament sequence is an increasing sequence of positive integers $(t_1, t_2, ...)$ such that $t_1 = 1$ and $t_{i+1} \leq 2t_i$. Cook and Kleber (2000) show that Meeussen sequences are isomorphic to tournament sequences.

Tower of Power

Power Tower

Towers of Hanoi

A puzzle invented by E. Lucas in 1883. Given a stack of n disks arranged from largest on the bottom to smallest on top placed on a rod, together with two empty rods, the towers of Hanoi puzzle asks for the minimum number of moves required to reverse the order of the stack (where moves are allowed only if they place smaller disks on top of larger disks). The

problem is ISOMORPHIC to finding a HAMILTONIAN PATH on an n-HYPERCUBE (Gardner 1957, 1959).

For n disks, the number of moves h_n required is given by the RECURRENCE RELATION

$$h_n = 2h_{n-1} + 1.$$

Solving gives

$$h_n = 2^n - 1.$$

The number of disks moved after the kth step is the same as the element which needs to be added or deleted in the kth ADDEND of the RYSER FORMULA (Gardner 1988, Vardi 1991). The number of disk to be moved at nth step of the optimal solution to the problem are 1, 2, 1, 3, 1, 2, 1, 4, 1, 2, 1, 3, 1, 2, ... (Sloane's A001511). Amazingly, this is exactly the BINARY CARRY SEQUENCE plus one.

A HANOI GRAPH can be constructed whose VERTICES correspond to legal configurations of n towers of Hanoi, where the VERTICES are adjacent if the corresponding configurations can be obtained by a legal move. It can be solved using a binary GRAY CODE.

Poole (1994) gives *Mathematica* routines for solving an arbitrary disk configuration in the fewest possible moves. The proof of minimality is achieved using the LUCAS CORRESPONDENCE which relates PASCAL'S TRIANGLE to the HANOI GRAPH. ALGORITHMS are known for transferring disks for four pegs, but none has been proved minimal. For additional references, see Poole (1994).

Trace (Group)

CHARACTER (GROUP)

Trace (Map)

Let a PATCH be given by the map $\mathbf{x} : U \to \mathbb{R}^n$, where U is an open subset of $\mathbb{R}^2$, or more generally by $\mathbf{x} : A \to \mathbb{R}^n$, where A is any SUBSET of $\mathbb{R}^2$. Then $\mathbf{x}(U)$ (or more generally, $\mathbf{x}(A)$) is called the trace of $\mathbf{x}$.

See also PATCH

References

Gray, A. *Modern Differential Geometry of Curves and Surfaces with Mathematica, 2nd ed.* Boca Raton, FL: CRC Press, pp. 269–270, 1997.

Trace (Matrix)

The trace of an $n \times n$ SQUARE MATRIX A is defined to be

$$\operatorname{Tr}(\mathsf{A}) \equiv \sum_{i=1}^{n} a_{ii}, \tag{1}$$

i.e., the sum of the diagonal elements. The matrix trace is implemented in *Mathematica* as `Tr[list]`. In GROUP THEORY, traces are known as "CHARACTERS."

For SQUARE MATRICES A and B, it is true that

$$\operatorname{Tr}(\mathsf{A}) = \operatorname{Tr}(\mathsf{A}^{\mathrm{T}}) \tag{2}$$

$$\operatorname{Tr}(\mathsf{A}+\mathsf{B}) = \operatorname{Tr}(\mathsf{A}) + \operatorname{Tr}(\mathsf{B}) \tag{3}$$

$$\operatorname{Tr}(\alpha\mathsf{A}) = \alpha\operatorname{Tr}(\mathsf{A}) \tag{4}$$

(Lange 1987, p. 40), where A^{T} denotes the TRANSPOSE. The trace is also invariant under a SIMILARITY TRANSFORMATION

$$\mathsf{A}' \equiv \mathsf{B}\mathsf{A}\mathsf{B}^{-1} \tag{5}$$

(Lange 1987, p. 64). Since

$$(bab^{-1})_{ij} = b_{il} a_{lk} b_{kj}^{-1} \tag{6}$$

(where EINSTEIN SUMMATION is used here to sum over repeated indices), it follows that

$$\begin{aligned}\operatorname{Tr}(\mathsf{B}\mathsf{A}\mathsf{B}^{-1}) &= b_{il} a_{lk} b^{-1}{}_{ki} \\ &= (b^{-1}b)_{kl} a_{lk} = \delta_{kl} a_{lk} \\ &= a_{kk} = \operatorname{Tr}(\mathsf{A}),\end{aligned} \tag{7}$$

where δ_{ij} is the KRONECKER DELTA.

The trace of a product of two square matrices is independent of the order of the multiplication since

$$\begin{aligned}\operatorname{Tr}(\mathsf{A}\mathsf{B}) &= (ab)_{ii} = a_{ij} b_{ji} = b_{ji} a_{ij} \\ &= (ba)_{jj} = \operatorname{Tr}(\mathsf{B}\mathsf{A})\end{aligned} \tag{8}$$

(again using EINSTEIN SUMMATION). Therefore, the trace of the COMMUTATOR of A and B is given by

$$\operatorname{Tr}([\mathsf{A}, \mathsf{B}]) \equiv \operatorname{Tr}(\mathsf{A}\mathsf{B}) - \operatorname{Tr}(\mathsf{B}\mathsf{A}) = 0. \tag{9}$$

The trace of a product of three or more square matrices, on the other hand, is invariant only under CYCLIC PERMUTATIONS of the order of multiplication of the matrices, by a similar argument.

The product of a SYMMETRIC and an ANTISYMMETRIC MATRIX has zero trace,

$$\operatorname{Tr}(A_S B_A) = 0. \tag{10}$$

The value of the trace can be found using the fact that the matrix can always be transformed to a coordinate system where the z-AXIS lies along the axis of rotation. In the new coordinate system (which is assumed to also have been appropriately rescaled), the MATRIX is

$$\mathsf{A}' = \begin{bmatrix} \cos\phi & \sin\phi & 0 \\ -\sin\phi & \cos\phi & 0 \\ 0 & 0 & 1 \end{bmatrix}, \tag{11}$$

so the trace is

$$\operatorname{Tr}(\mathsf{A}') = \operatorname{Tr}(\mathsf{A}) \equiv a_{ii} = 1 + 2\cos\phi. \tag{12}$$

Munkres, J. R. *Elements of Algebraic Topology.* Perseus Press, p. 122, 1993.

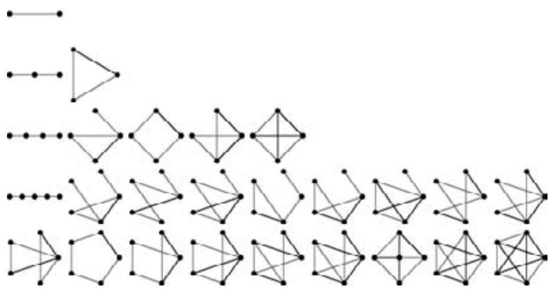
Trace (Path)

The image of the path γ in $\mathbb{C}$ under the FUNCTION f is called the trace. This usage of the term "trace" is unrelated to the same term applied to MATRICES or TENSORS.

Trace (Tensor)

The trace of a second-RANK TENSOR T is a SCALAR given by the CONTRACTED mixed TENSOR equal to T^i_i. The trace is implemented in *Mathematica* as `Tr[list]`.

The trace satisfies



$$\operatorname{Tr}\left[M^{-1}(x)\frac{\partial}{\partial x^\lambda} M(x)\right] = \frac{\partial}{\partial x^\lambda} \ln[\det(x)],$$

and

$$\begin{aligned}\delta \ln[\det M] &= \ln[\det(M+\delta M)] - \ln(\det M) \\ &= \ln\left[\frac{\det(M+\delta M)}{\det M}\right] \\ &= \ln[\det M^{-1}(M+\delta M)] \\ &= \ln[\det(1+M^{-1}\delta M)] \\ &\approx \ln[1+\operatorname{Tr}(M^{-1}\delta M)] \\ &\approx \operatorname{Tr}(M^{-1}\delta M).\end{aligned}$$

See also CHARACTER (GROUP), CONTRACTION (TENSOR), TRACE (MATRIX)

Traceable Graph

A GRAPH G that possesses a HAMILTONIAN PATH. HAMILTONIAN GRAPHS are therefore traceable, but the converse is not necessarily true. The number of traceable graphs on $n = 1, 2, ...$ are 0, 1, 2, 5, 18, 91, 734, ... (Sloane's A057864), the first few of which are illustrated above.

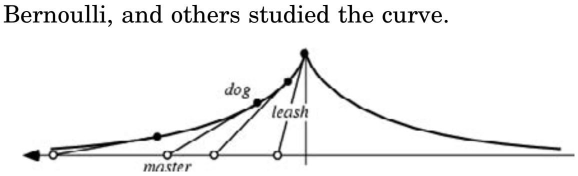
Tractory

TRACTRIX



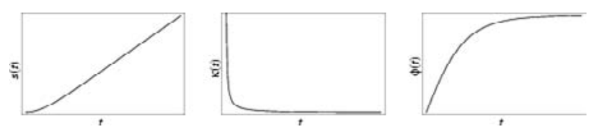
Tractrisoid

PSEUDOSPHERE

Tractrix

The tractrix is the CATENARY INVOLUTE described by a point initially on the vertex (making the CATENARY the TRACTRIX EVOLUTE). The tractrix is sometimes called the TRACTORY or EQUITANGENTIAL CURVE. The tractrix was first studied by Huygens in 1692, who gave it the name "tractrix." Later, Leibniz, Johann Bernoulli, and others studied the curve.

The tractrix arises from the following problem posed to Leibniz: What is the path of an object starting off with a vertical offset when it is dragged along by a string of constant length being pulled along a straight horizontal line (Steinhaus 1983, pp. 250–251)? By associating the object with a dog, the string with a leash, and the pull along a horizontal line with the dog's master, the curve has the descriptive name HUNDKURVE (hound curve) in German. Leibniz found the curve using the fact that the axis is an asymptote to the tractrix (MacTutor Archive).



In CARTESIAN COORDINATES the tractrix has equation

$$x = a \operatorname{sech}^{-1}\left(\frac{y}{a}\right) - \sqrt{a^2 - y^2}. \quad (1)$$

One parametric form is

$$x(t) = a(t - \tanh t) \quad (2)$$

$$y(t) = a \operatorname{sech} t. \quad (3)$$

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE in this parameterization are

$$s(t) = \ln(\cosh t) \quad (4)$$

$$\kappa(t) = \operatorname{csch} t \quad (5)$$

$$\phi(t) = 2\tan^{-1}\left[\tanh\left(\tfrac{1}{2}t\right)\right]. \quad (6)$$

A second parametric form in terms of the ANGLE θ of the straight line tangent to the tractrix can be found by computing

$$\theta(t) = \tan^{-1}\left(\frac{\frac{dy}{dt}}{\frac{dx}{dt}}\right) = \tan^{-1}\left(\frac{-\operatorname{sech} t \tanh t}{\tanh^2 t}\right)$$

$$= -\tanh^{-1}(\operatorname{csch} t), \quad (7)$$

then solving for t and plugging back in to obtain

$$x = a \leq \left\{\ln\left[\tan\left(\tfrac{1}{2}\theta\right)\right] + \cos\theta\right\} \quad (8)$$

$$= a\left\{-\operatorname{csch}^{-1}(\tan\theta) + \cos\theta\right\} \quad (9)$$

$$y = a\sin\theta \quad (10)$$

(Gray 1997). This parameterization has CURVATURE

$$\kappa(\theta) = |\tan\theta|. \quad (11)$$

In terms of the angle $\theta' = \pi/2 + \theta$, the PARAMETRIC EQUATIONS can be written

$$x = a \operatorname{gd}^{-1}\theta' - \sin\theta \quad (12)$$

$$= a[\ln(\sec\theta' + \tan\theta') - \sin\theta'] \tag{13}$$

$$= a\left\{\ln\left[\tan\left(\tfrac{1}{2}\theta' + \tfrac{1}{4}\pi\right)\right] - \sin\theta'\right\} \tag{14}$$

$$y = a\cos\theta' \tag{15}$$

(Lockwood 1967, p. 123), where $\mathrm{gd}^{-1}\, x$ is the inverse GUDERMANNIAN FUNCTION.

A parameterization which traverses the tractrix with constant speed a is given by

$$x(t) = \begin{cases} ae^{-v/a} & \text{for } v \in [0, \infty) \\ ae^{v/a} & \text{for } v \in (-\infty, 0] \end{cases} \tag{16}$$

$$y(t) = \begin{cases} a\left[\tanh^{-1}\left(\sqrt{1-e^{-2v/a}}\right) - \sqrt{1-e^{-2v/a}}\right] \\ \quad \text{for } v \in [0, \infty) \\ a\left[-\tanh^{-1}\left(\sqrt{1-e^{2v/a}}\right) + \sqrt{1-e^{2v/a}}\right] \\ \quad \text{for } v \in (-\infty, 0]. \end{cases} \tag{17}$$

When a tractrix is rotated around its asymptote, a PSEUDOSPHERE results. This is a surface of constant NEGATIVE CURVATURE. For a tractrix, the length of a TANGENT from its point of contact to an asymptote is constant. The AREA between the tractrix and its asymptote is finite.

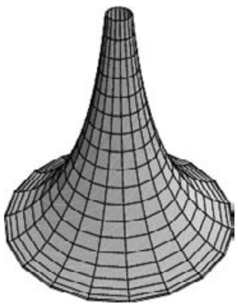
Tractrix Evolute



The EVOLUTE of the TRACTRIX is the CATENARY.

Tractrix Radial Curve

The RADIAL CURVE of the TRACTRIX is the KAPPA CURVE.

Tractroid

The SURFACE OF REVOLUTION produced by revolving the TRACTRIX

$$x = \operatorname{sech} u \tag{1}$$

$$z = u - \tanh u \tag{2}$$

about the z-AXIS is a tractroid given by

$$x = \operatorname{sech} u \cos v \tag{3}$$

$$y = \operatorname{sech} u \sin v \tag{4}$$

$$z = u - \tanh u. \tag{5}$$

See also PSEUDOSPHERE, SURFACE OF REVOLUTION, TRACTRIX

Trail

PATH, WALK

Transcendental Curve

A curve which intersects some straight line in an infinity of points (but for which not every point lies on this curve).

See also ALGEBRAIC CURVE

Transcendental Equation

An equation or formula involving TRANSCENDENTAL FUNCTIONS.

Transcendental Function

A function which is not an ALGEBRAIC FUNCTION. In other words, a function which "transcends," i.e., cannot be expressed in terms of, algebra. Examples of transcendental functions include the EXPONENTIAL FUNCTION, the TRIGONOMETRIC FUNCTIONS, and the inverses functions of both.

See also ALGEBRAIC FUNCTION, ELEMENTARY FUNCTION, PAINLEVÉ TRANSCENDENTS

Transcendental Number

A number which is not the ROOT of *any* POLYNOMIAL equation with INTEGER COEFFICIENTS, meaning that it is not an ALGEBRAIC NUMBER of any degree, is said to be transcendental. This definition guarantees that every transcendental number must also be IRRATIONAL, since a RATIONAL NUMBER is, by definition, an ALGEBRAIC NUMBER of degree one. A number x can then be tested to see if it is transcendental using the *Mathematica* command `Not[Element[x, Algebraics]]`.

Transcendental numbers are important in the history of mathematics because their investigation provided the first proof that CIRCLE SQUARING, one of the GEOMETRIC PROBLEMS OF ANTIQUITY which had baffled mathematicians for more than 2000 years was, in fact, insoluble. Specifically, in order for a number to be produced by a GEOMETRIC CONSTRUCTION using the ancient Greek rules, it must be either RATIONAL or a very special kind of ALGEBRAIC NUMBER known as a EUCLIDEAN NUMBER. Because the number π is transcendental, the construction cannot be done according to the Greek rules.

Georg Cantor was the first to prove the EXISTENCE of transcendental numbers. Liouville subsequently showed how to construct special cases (such as LIOUVILLE'S CONSTANT) using LIOUVILLE'S APPROXIMATION THEOREM. In particular, he showed that any number which has a rapidly converging sequence of rational approximations must be transcendental. For many years, it was only known how to determine if special classes of numbers were transcendental. The determination of the status of more general numbers was considered an important enough unsolved problem that it was one of HILBERT'S PROBLEMS.

Great progress was subsequently made by GELFOND'S THEOREM, which gives a general rule for determining if special cases of numbers OF THE FORM α^β are transcendental. Baker produced a further revolution by proving the transcendence of sums of numbers OF THE FORM $\alpha \ln \beta$ for ALGEBRAIC NUMBERS α and β.

The number E was proven to be transcendental by Hermite in 1873, and PI (π) by Lindemann in 1882. e^π is transcendental by GELFOND'S THEOREM since

$$(-1)^{-i} = (e^{i\pi})^{-i} = e^\pi.$$

The GELFOND-SCHNEIDER CONSTANT $2^{\sqrt{2}}$ is also transcendental (Hardy and Wright 1979, p. 162). Known transcendentals are summarized in the following table, where $\sin x$ is the SINE function, $J_0(x)$ is a BESSEL FUNCTION OF THE FIRST KIND, $x_k^{(n)}$ is the nth zero of $J_k(x)$, P is the THUE-MORSE CONSTANT, $\Gamma(x)$ is the GAMMA FUNCTION, and where $\zeta(n)$ is the RIEMANN ZETA FUNCTION.

e	Hermite (1873)
π	Lindemann (1882)
e^π	Gelfond
$e^{\pi\sqrt{d}}$, $d \in Z^*$	Nesterenko (1999)
$2^{\sqrt{2}}$	Hardy and Wright (1979, p. 162)
$\sin 1$	Hardy and Wright (1979, p. 162)
$J_0(1)$	Hardy and Wright (1979, p. 162)
$\ln 2$	Hardy and Wright (1979, p. 162)
$\ln 3/\ln 2$	Hardy and Wright (1979, p. 162),
$x_0^{(1)} = 2.4048255\ldots$	Le Lionnais (1983, p. 46)
$\pi + \ln 2 + \sqrt{2} \ln 3$	Borwein *et al.* (1989)
$P = 0.4124540336\ldots$	Dekking (1977), Allouche and Shallit
CHAMPERNOWNE CONSTANT	
THUE CONSTANT	
$\Gamma\left(\frac{1}{3}\right)$	Le Lionnais (1983, p. 46)
$\Gamma\left(\frac{1}{4}\right)$	Chudnovsky (1984, p. 308), Waldschmidt, Nesterenko (1999)
$\Gamma\left(\frac{1}{6}\right)$	Chudnovsky (1984, p. 308)
$\Gamma\left(\frac{1}{4}\right)\pi^{-1/4}$	Davis (1959)
$\zeta(2n)$, $n \in \mathbb{Z} > 1$	

APÉRY'S CONSTANT $\zeta(3)$ has been proved to be IRRATIONAL, but it is not known if it is transcendental. At least one of πe and $\pi + e$ (and probably both) are transcendental, but transcendence has not been proven for either number on its own. It is not known if e^e, π^π, π^e, γ (the EULER-MASCHERONI CONSTANT), $I_0(2)$, or $I_1(2)$ (where $I_n(x)$ is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND) are transcendental.

The "degree" of transcendence of a number can be characterized by a so-called IRRATIONALITY MEASURE. There are still many fundamental and outstanding problems in transcendental number theory, including the CONSTANT PROBLEM and SCHANUEL'S CONJECTURE.

Transcritical Bifurcation

Let $f : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ be a one-parameter family of C^2 maps satisfying

$$f(0, \mu) = 0 \tag{1}$$

$$\left[\frac{\partial f}{\partial x}\right]_{\mu=0,\ x=0} = 0 \tag{2}$$

$$\left[\frac{\partial^2 f}{\partial x\, \partial \mu}\right]_{0,\ 0} > 0 \tag{3}$$

$$\left[\frac{\partial^2 f}{\partial x^2}\right]_{\mu=0,\ x=0} < 0. \tag{4}$$

(Actually, condition (1) can be relaxed slightly.) Then there are two branches, one stable and one unstable. This BIFURCATION is called a transcritical bifurcation.

An example of an equation displaying a transcritical bifurcation is

$$\dot{x} = \mu x - x^2 \tag{5}$$

(Guckenheimer and Holmes 1997, p. 145).

Transfer Function

The engineering terminology for one use of FOURIER TRANSFORMS. By breaking up a wave pulse into its frequency spectrum

$$f_\nu = F(\nu) e^{2\pi i \nu t}, \tag{1}$$

the entire signal can be written as a sum of contribu-

tions from each frequency,

$$f(t) = \int_{-\infty}^{\infty} f_v \, dv = \int_{-\infty}^{\infty} F(v) e^{2\pi i v t} \, dv. \qquad (2)$$

If the signal is modified in some way, it will become

$$g_v(t) = \phi(v) f_v(t) = \phi(v) F(v) e^{2\pi i v t} \qquad (3)$$

$$g(t) = \int_{-\infty}^{\infty} g_v(t) \, dt = \int_{-\infty}^{\infty} \phi(v) F(v) e^{2\pi i v t} \, dv, \qquad (4)$$

where $\phi(v)$ is known as the "transfer function." FOURIER TRANSFORMING ϕ and F,

$$\phi(v) = \int_{-\infty}^{\infty} \Phi(t) e^{-2\pi i v t} \, dt \qquad (5)$$

$$F(v) = \int_{-\infty}^{\infty} f(t) e^{-2\pi i v t} \, dt. \qquad (6)$$

From the CONVOLUTION THEOREM,

$$g(t) = f(t) * \Phi(t) = \int_{-\infty}^{\infty} f(t) \Phi(t - r) \, dr. \qquad (7)$$

See also CONVOLUTION THEOREM, FOURIER TRANSFORM

Transfer Principle

In NONSTANDARD ANALYSIS, the transfer principle is the technical form of the following intuitive idea: "Anything provable about a given SUPERSTRUCTURE V by passing to a nonstandard enlargement $*V$ of V is also provable without doing so, and vice versa." It is a result of LOS' THEOREM and the completeness theorem for first-order predicate logic

The transfer principle is stated as follows. Let V be a superstructure, let $*V$ be an enlargement of V, let σ be any sentence in the language for $(V, \in)$, and let $*\sigma$ denote the $*$-transform of σ. Then $(V, \in) \models \sigma$ if and only if $(*V, *\in) \models *\sigma$.

See also LOS' THEOREM, NONSTANDARD ANALYSIS

Transfinite Diameter

Let

$$\phi(z) = cz + c_0 + c_1 z^{-1} + c_2 z^{-2} + \ldots$$

be an ANALYTIC FUNCTION, REGULAR and UNIVALENT for $|z| > 1$, which maps $|z| > 1$ CONFORMALLY onto the region T preserving the POINT AT INFINITY and its direction. Then the function $\phi(z)$ is uniquely determined and c is called the transfinite diameter, sometimes also known as ROBIN'S CONSTANT or the CAPACITY of $\phi(z)$.

See also ANALYTIC FUNCTION, REGULAR FUNCTION, UNIVALENT FUNCTION

Transfinite Number

One of Cantor's ORDINAL NUMBERS ω, $\omega + 1$, $\omega + 2$, ..., $\omega + \omega$, $\omega + \omega + 1$, ...which is "larger" than any WHOLE NUMBER.

Transform Theory

INTEGRAL TRANSFORM

Transformation

A transformation T (a.k.a., MAP, FUNCTION) over a DOMAIN D takes the elements $X \in D$ to elements $Y \in T(D)$, where the RANGE (a.k.a., image) of T is defined as

$$\mathrm{Range}(T) = T(D) = \{T(\mathbf{X}) : \mathbf{X} \in D\}.$$

Note that when transformations are specified with respect to a coordinate system, it is important to specify whether the rotation takes place on the *coordinate system*, with space and objects embedded in it being viewed as fixed (a so-called ALIAS TRANSFORMATION), or on the *space itself* relative to a fixed coordinate system (a so-called ALIBI TRANSFORMATION).

Examples of transformations are summarized in the following table.

Transformation	Characterization
DILATION	center of dilation, scale decrease factor
EXPANSION	center of expansion, scale increase factor
REFLECTION	mirror line or plane
ROTATION	center of rotation, rotation angle
SHEAR	invariant line and SHEAR FACTOR
STRETCH (1-way)	invariant line and scale factor
STRETCH (2-way)	invariant lines and scale factors
TRANSLATION	displacement vector

See also AFFINE TRANSFORMATION, ALIAS TRANSFORMATION, ALIBI TRANSFORMATION, DILATION, EXPANSION, FUNCTION, MAP, REFLECTION, ROTATION, SHEAR, STRETCH, TRANSFORM, TRANSLATION

Transition Function

A transition function describes the difference in the way an object is described in two separate, overlapping COORDINATE CHARTS, where the description of the same set may change in different coordinates. This even occurs in EUCLIDEAN SPACE $\mathbb{R}^3$, where any rotation of the usual x, y, and z axes gives another set of coordinates.

For example, on the sphere, person A at the equator can use the usual directions of north, south, east, and west, but person B at the North Pole must use something else. However, both A and B can describe the region in between them in their coordinate charts. A transition function would then describe how to go from the coordinate chart for A to the coordinate chart for B.

In the case of a MANIFOLD, a transition function is a map from one coordinate chart to another. Therefore, in a sense, a manifold is composed of coordinate charts, and the glue that holds them together is the transition functions. In the case of a BUNDLE, the transition functions are the glue that holds together its TRIVIALIZATIONS. Specifically, in this case the transition function describes an invertible transformation of the FIBER.

Naturally, the type of invertible transformation depends on the type of bundle. For instance, a VECTOR BUNDLE, which could be the TANGENT BUNDLE, has INVERTIBLE LINEAR transition functions. More precisely, a transition function for a vector bundle of RANK r, on overlapping coordinate charts U_1 and U_2, is given by a function

$$g_{12} : U_1 \cap U_2 \to GL(r),$$

where GL is the GENERAL LINEAR GROUP. The fiber at $p \in U_1 \cap U_2$ has two descriptions, and $g_{12}(p)$ is the INVERTIBLE LINEAR MAP that takes one to the other. The transition functions have to be consistent in the sense that if one goes to another description of the same set, and then back again, then nothing has changed. A necessary and sufficient condition for consistency is the following: Given three overlapping charts, the product $g_{12}g_{23}g_{31}$ has to be the constant map to the identity in $GL(r)$.

A consistent set of transition functions for a VECTOR BUNDLE of RANK r can be interpreted as an element of the first CECH COHOMOLOGY GROUP of a manifold with coefficients in $GL(r)$.

See also BUNDLE, CECH COHOMOLOGY, COORDINATE CHART, MANIFOLD, TANGENT BUNDLE, TRIVIALIZATION, VECTOR BUNDLE

Transitive

A RELATION R on a SET S is transitive provided that for all x, y and z in S such that xRy and yRz, we also have xRz.

See also ASSOCIATIVE, COMMUTATIVE, RELATION

Transitive Closure

The transitive closure of a BINARY RELATION R on a SET X is the minimal TRANSITIVE relation R' on X that contains R. Thus $aR'b$ for any elements a and b of X provided that there exist $c_0, c_1, ..., c_n$ with $c_0 = a$, $c_n = b$, and $c_r R c_{r+1}$ for all $0 \le r \le n$.

The transitive closure $C(G)$ of a GRAPH is a graph which contains an edge $\{u, v\}$ whenever there is a directed path from u to v (Skiena 1990, p. 203). The transitive closure of a graph can be computed using `TransitiveClosure[g]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

Transitive Digraph

A GRAPH G is transitive if any three vertices (x, y, z) such that edges $(x, y), (y, z) \in G$ imply $(x, y) \in G$. Unlabeled transitive digraphs are called TOPOLOGIES.

See also TOPOLOGY (DIGRAPH), TRANSITIVE GRAPH, TRANSITIVE REDUCTION

Transitive Graph

A GRAPH G is called n-transitive with $n \geq 1$ if it has an n-ROUTE and if there is always a GRAPH AUTOMORPHISM of G sending each n-ROUTE onto any other n-ROUTE (Harary 1994, p. 173). There are no n-transitive CUBIC GRAPHS for $n > 5$ (Harary 1994, p. 175).

Transitive Group

When a GROUP ACTION is implicitly understood, i.e., a subgroup of a PERMUTATION GROUP, then the SUBGROUP is called transitive if its action is transitive. For example, the ALTERNATING GROUP is transitive. A group may also be called k-transitive if there is any set on which the group acts FAITHFULLY and k-transitively. Transitivity is a result of the symmetry in the group.

For instance, the SYMMETRIC GROUP S_n is n-transitive and the ALTERNATING GROUP A_n is $(n-2)$-transitive. However, multiply transitive finite groups are rare. In fact, they have been completely determined using the CLASSIFICATION THEOREM OF FINITE GROUPS. Except for some SPORADIC examples, the multiply transitive groups fall into infinite families. Certain subgroups of the AFFINE GROUP on a finite VECTOR SPACE, including the AFFINE GROUP itself, are 2-transitive. Some of these are summarized below.

The multiply transitive groups fall into six infinite families, and four classes of SPORADIC GROUPS. In the following enumeration, q is a power of a prime number.

1. Certain subgroups of the AFFINE GROUP on a finite VECTOR SPACE, including the AFFINE GROUP itself, are 2-transitive.
2. The PROJECTIVE SPECIAL LINEAR GROUPS $PSL(d, q)$ are 2-transitive, and $PSL(2, q)$ is actually 3-transitive.
3. The SYMPLECTIC GROUPS defined over the FIELD of two elements have two distinct actions which are 2-transitive.
4. The field K of q^2 elements has an INVOLUTION $\sigma(a) = a^q$, so $\sigma^2 = 1$, which allows a HERMITIAN FORM to be defined on a VECTOR SPACE on K. The UNITARY GROUP on $V = \bigoplus^3 K$, denoted $U_2(q)$, preserves the ISOTROPIC VECTORS in V. The action of the PROJECTIVE SPECIAL UNITARY GROUP $PSU_3(q)$ is 2-transitive on the ISOTROPIC VECTORS.
5. The SUZUKI GROUP $Sz(q)$ is the AUTOMORPHISM GROUP of a $S(3, q+1, q^2+1)$ STEINER SYSTEM, an INVERSIVE PLANE of order q, and its action is 2-transitive.
6. The REE GROUP $R(q)$ is the AUTOMORPHISM GROUP of a $S(2, q+1, q^3+1)$ STEINER SYSTEM, a UNITAL of order q, and its action is 2-transitive.
7. The MATHIEU GROUPS M_{12} and M_{24} are the only 5-transitive groups besides S_5 and A_7. The groups M_{11} and M_{23} are 4-transitive, and M_{22} is 3-transitive.
8. The PROJECTIVE SPECIAL LINEAR GROUP $PSL(2, 11)$ has another 2-transitive action related to the WITT GEOMETRY W_{11}.
9. The HIGMAN-SIMS GROUP is 2-transitive.
10. The CONWAY GROUP Co_3 is 2-transitive.

References

Dixon, J. and Mortimer, B. *Permutation Groups.* New York: Springer-Verlag, 1996.

Transitive Group Action

A GROUP ACTION $G \times X \to X$ is transitive if it possesses only a single ORBIT, i.e., for every pair of elements x and y, there is a group element g such that $gx = y$. In this case, X is ISOMORPHIC to the left COSETS of the isotropy group, $X \sim G/G_x$. The space X, which has a transitive group action, is called a HOMOGENEOUS SPACE when the group is a LIE GROUP.

If, for every two pairs of points x_1, x_2 and y_1, y_2, there is a group element g such that $gx_i = y_i$, then the GROUP ACTION is called doubly transitive. Similarly, a group action can be triply transitive and, in general, a GROUP ACTION is k-transitive if every set $\{x_1, \ldots, y_k\}$ of $2k$ distinct elements has a group element g such that $gx_i = y_i$.

Transitive Points

Two points on a surface which are opposite to each other but not farthest from each other (e.g., the midpoints of opposite edges of a CUBE) are said to be transitive points. The SPHERE has no transitive points.

References

Steinhaus, H. *Mathematical Snapshots, 3rd ed.* New York: Dover, p. 175, 1999.

Transitive Reduction

The transitive reduction of a BINARY RELATION R on a SET X is the minimum relation R' on X with the same TRANSITIVE CLOSURE as R. Thus $aR'b$ for any elements a and b of X, provided that aRb and there exists no element c of X such that aRc and cRb.

The transitive reduction of a GRAPH G is the smallest graph $R(G)$ such that $C(G) = C(R(G))$, where $C(G)$ is the TRANSITIVE CLOSURE of G (Skiena 1990, p. 203).

Translation Relation

A mathematical relationship transforming a function $f(x)$ to the form $f(x+a)$.

See also Argument Addition Relation, Argument Multiplication Relation, Recurrence Relation, Reflection Relation

Transpose

The object obtained by replacing all elements a_{ij} with a_{ji}. For a second-rank tensor a_{ij}, the tensor transpose is simply a_{ji}. The matrix transpose, written A^{T}, is the matrix obtained by exchanging A's rows and columns, and satisfies the identity

$$(\mathsf{A}^{\mathrm{T}})^{-1} = (\mathsf{A}^{-1})^{\mathrm{T}}. \quad (1)$$

Several other notations are commonly used, including $\tilde{\mathsf{A}}$ (Arfken 1985, p. 201; Griffiths 1987, p. 223) and A' (Ayres 1962, p. 11; Courant and Hilbert 1989, p. 9)

The product of two transposes satisfies

$$(\mathsf{B}^{\mathrm{T}}\mathsf{A}^{\mathrm{T}})_{ij} = (b^{\mathrm{T}})_{ik}(a^{\mathrm{T}})_{kj} = b_{ki}a_{jk} = a_{jk}b_{ki} = (\mathsf{AB})_{ji}$$
$$= (\mathsf{AB})^{\mathrm{T}}_{ij}, \quad (2)$$

where Einstein summation has been used to implicitly sum over repeated indices. Therefore,

$$(\mathsf{AB})^{\mathrm{T}} = \mathsf{B}^{\mathrm{T}}\mathsf{A}^{\mathrm{T}}. \quad (3)$$

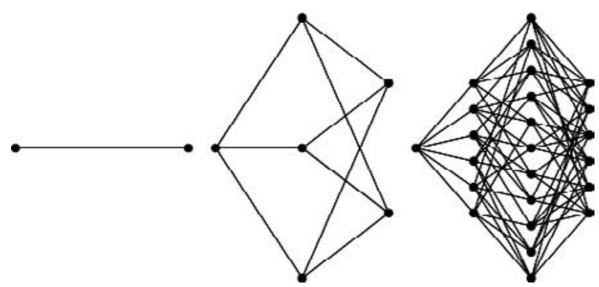
Transpose Map

Pullback Map

Transpose Partition

Conjugate Partition

Transposition



An exchange of two elements of an ordered list with all others staying the same. A transposition is therefore a permutation of two elements. For example, the swapping of 2 and 5 to take the list 123456 to 153426 is a transposition. The permutation symbol $\epsilon_{ijk\cdots}$ is defined as $(-1)^n$, where n is the number of transpositions of pairs of elements that must be composed to build up the permutation.

References

Skiena, S. "Permutations from Transpositions." §1.1.4 in *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, pp. 9–11, 1990.

Transposition Graph

A graph in which nodes correspond to permutations and edges are placed between permutations that differ by exactly one transposition (Skiena 1990, p. 9). All cycles in transposition graphs are of even length, making them bipartite. The transposition graph of a multiset is always Hamiltonian (Chase 1973).

See also Transposition

Transposition Group

A permutation group in which the permutations are limited to transpositions.

See also Permutation Group

Transposition Order

An ordering of permutations in which each two adjacent permutations differ by the transposition of two elements. For the permutations of $\{1, 2, 3\}$ there are two listings which are in transposition order. One

is 123, 132, 312, 321, 231, 213, and the other is 123, 321, 312, 213, 231, 132.

Transversal Array

A set of n cells in an $n \times n$ SQUARE such that no two come from the same row and no two come from the same column. The number of transversals of an $n \times n$ SQUARE is $n!$ (n FACTORIAL).

A Latin transversal is a transversal such that no two cells contain the same element (Snevily 1999).

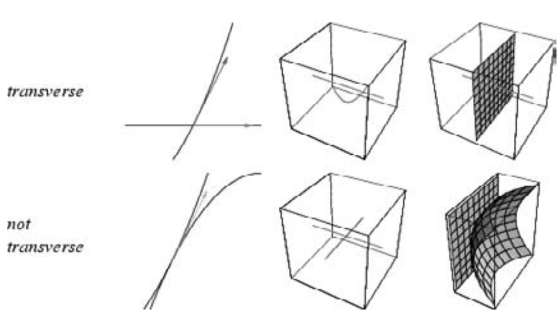
Transversal Design



A transversal design $\mathrm{TD}_\lambda(k,\ n)$ of order n, block size k, and index λ is a triple (V, G, B) such that

1. V is a set of kn elements,
2. G is a partition of V into k classes, each of size n (the "groups"),
3. B is a collection of k-subsets of V (the "blocks"), and
4. Every unordered pair of elements from V is contained in either exactly one group or in exactly λ blocks, but not both.

Transversal Intersection

Two SUBMANIFOLDS X and Y in an ambient space M intersect transversally if, for all $p \in X \cap Y$,

$$TX_p + TY_p = \{v + w : v \in TX_p,\ w \in TY_p\} = TM_p,$$

where the addition is in TM_p, and TX_p denotes the TANGENT MAP of X_p. If two submanifolds do not intersect, then they are automatically transversal. For example, two curves in $\mathbb{R}^3$ are transversal only if they do not intersect at all. When X and Y meet transversally then $X \cap Y$ is a smooth SUBMANIFOLD of the expected dimension $\dim X + \dim Y - \dim M$.
In some sense, two submanifolds "ought" to intersect transversally and, by SARD'S THEOREM, any intersection can be perturbed to be transversal. Intersection in HOMOLOGY only makes sense because an intersection can be made to be transversal.

Transversality is a sufficient condition for an intersection to be stable after a perturbation. For example, the lines $y = x$ and $y = 0$ intersect transversally, as do the perturbed lines $y = x + t$, and they intersect at only one point. However, $y = x^2$ does not intersect $y = 0$ transversally. It intersects in one point, while $y = x^2 + t$ intersects in either none or two points, depending on whether t is positive or negative.

When $\dim X + \dim Y = \dim M$, then a transversal intersection is an ISOLATED POINT. If the three spaces have an ORIENTATION, then the transversal condition means it is possible to assign a sign to the intersection. If $e_1, \ldots, e_k$ are an oriented basis for TX_p and $e_{k+1}, \ldots, e_n$ are an oriented basis for TY_p, then the intersection is +1 if $e_1, \ldots, e_n$ is oriented in M and -1 otherwise.

More generally, two SMOOTH MAPS $f : X \to M$ and $g : Y \to M$ are transversal if whenever $p = f(x) = g(y)$ then $df(TX_x) + dg(TY_y) = TM_p$.

See also HOMOLOGY, INTERSECTION (HOMOLOGY), ORIENTATION (VECTOR SPACE), SARD'S THEOREM, SUBMERSION

Transversal Line

A transversal line is a LINE which intersects each of a given set of other lines. It is also called a semisecant.

Trapdoor Function

An easily computed function whose inverse is extremely difficult to compute. An example is the multiplication of two large PRIMES. Finding and verifying two large PRIMES is easy, as is their multiplication. But factorization of the resultant product is very difficult.

See also RSA ENCRYPTION

References

Gardner, M. "Trapdoor Ciphers" and "Trapdoor Ciphers II." Chs. 13–14 in *Penrose Tiles and Trapdoor Ciphers...and the Return of Dr. Matrix, reissue ed.* New York: W. H. Freeman, pp. 183–204, 1989.

Trapdoor One-Way Function

Informally, a function $f:\{0,\ 1\}^{l(n)}\times\{0,\ 1\}^n\to(0,\ 1\}^{m(n)}$ is a trapdoor one-way function if

1. It is a ONE-WAY FUNCTION, and
2. For fixed public key $y\in\{0,\ 1\}^{l(n)}$, $f(x,\ y)$ is viewed as a function $f_y(x)$ of x that maps n bits to $m(n)$ bits. Then there is an efficient algorithm that, on input $\langle y,\ f_y(x),\ z\rangle$ produces x' such that $f_y(x')=f_y(x)$, for some trapdoor key $z\in\{0,\ 1\}^{k(n)}$.

f is a TRAPDOOR ONE-WAY HASH FUNCTION if f is also a ONE-WAY HASH FUNCTION, i.e., if additionally

3. Given M and $f(M)$, it is hard to find a message $M'\neq M$ such that $f(M')\neq f(M)$.

It is not known if a trapdoor one-way function can be constructed from any one-way function.

An example of a trapdoor one-way function is factorization of a product of two large PRIMES. While selecting and verifying two large PRIMES and multiplying them together is easy, factoring the resulting product is (as far as is known) very difficult. This is the basis for RSA ENCRYPTION, which is conjectured to be trapdoor one-way.

See also ONE-WAY FUNCTION, RSA ENCRYPTION, TRAPDOOR ONE-WAY HASH FUNCTION

References

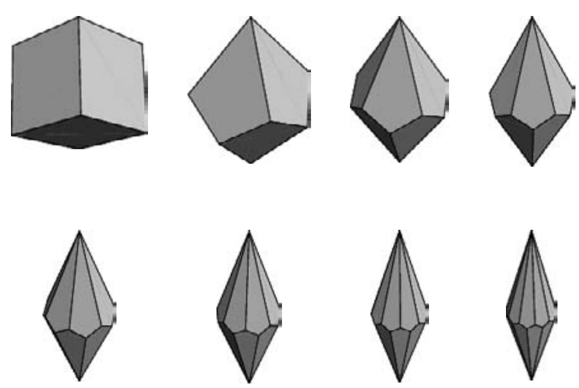
Trapdoor One-Way Hash Function

A function $f:\{0,\ 1\}^{l(n)}\times\{0,\ 1\}^n\to(0,\ 1\}^{m(n)}$ is a TRAPDOOR ONE-WAY HASH FUNCTION if f is a TRAPDOOR ONE-WAY FUNCTION and is also a one-way hash function, i.e. if, additionally given M and $f(M)$, it is hard to find a message $M'\neq M$ such that $f(M')=f(M)$.

See also TRAPDOOR ONE-WAY FUNCTION



Trapezium

There are two common definitions of the trapezium. The American definition is a QUADRILATERAL with no PARALLEL sides. The British definition for a trapezium is a QUADRILATERAL *with* two sides PARALLEL. Such a trapezium is equivalent to a TRAPEZOID and therefore has AREA

$$A=\tfrac{1}{2}(a+b)h.$$

See also DIAMOND, KITE, LOZENGE, PARALLELOGRAM, QUADRILATERAL, RHOMBOID, RHOMBUS, SKEW QUADRILATERAL, STROMBUS, TRAPEZOID

Trapezohedron

The trapezohedra are the DUAL POLYHEDRA of the Archimedean ANTIPRISMS. However, the name for these solids is not particular well chosen since their faces are *not* TRAPEZOIDS. The CUBE oriented along a space diagonal is a trapezohedron.

The trapezohedra generated by taking the duals of the ANTIPRISMS have side length s_n, half-heights (half the peak-to-peak distance) h_n, surface areas S_n, and volumes V_n (where the latter two are normalized so that the shortest edge has length 1) given by

$$s_3=\tfrac{1}{2}\sqrt{2} \tag{1}$$

$$h_3=\tfrac{1}{4}\sqrt{6} \tag{2}$$

$$S_3=6 \tag{3}$$

$$V_3=1 \tag{4}$$

$$s_4=\sqrt{\sqrt{2}-1},\ \sqrt{\tfrac{1}{2}\left(1+\sqrt{3}\right)} \tag{5}$$

$$h_4 = \tfrac{1}{2}\sqrt{h\left(4+3\sqrt{2}\right)} \quad (6)$$

$$S_4 = 2\sqrt{22+16\sqrt{2}} \quad (7)$$

$$V_4 = \tfrac{1}{3}\sqrt{58+41\sqrt{2}} \quad (8)$$

$$s_5 = \tfrac{1}{2}\left(\sqrt{5}-1\right),\ \tfrac{1}{2}\left(1+\sqrt{5}\right) \quad (9)$$

$$h_5 = \tfrac{1}{2}\sqrt{5+2\sqrt{5}} \quad (10)$$

$$S_5 = 5\sqrt{\tfrac{1}{2}\left(25+11\sqrt{5}\right)} \quad (11)$$

$$V_5 = \tfrac{5}{12}\left(11+5\sqrt{5}\right) \quad (12)$$

$$s_6 = \sqrt{\tfrac{1}{2}\left(\sqrt{3}-1\right)},\ \sqrt{\tfrac{1}{2}\left(5+3\sqrt{3}\right)} \quad (13)$$

$$h_6 = \tfrac{1}{4}\sqrt{38+22\sqrt{3}} \quad (14)$$

$$S_6 = 6\sqrt{24+14\sqrt{3}} \quad (15)$$

$$V_6 = 7\sqrt{2}+4\sqrt{6} \quad (16)$$

$$s_8 = \sqrt{1-\sqrt{2}+\sqrt{2-\sqrt{2}}},$$

$$\sqrt{\tfrac{1}{2}\left[8+5\sqrt{2}+\sqrt{2\left(58+41\sqrt{2}\right)}\right]} \quad (17)$$

$$h_8 = \frac{1}{2}\sqrt{\tfrac{1}{2}\left[30+20\sqrt{2}+\sqrt{2\left(850+601\sqrt{2}\right)}\right]} \quad (18)$$

$$S_8 = 4\sqrt{144+98\sqrt{2}+4\sqrt{2516+1778\sqrt{2}}} \quad (19)$$

$$V_8 = \tfrac{2}{3}\sqrt{2\left(1150+812\sqrt{2}+\sqrt{2641130+1867559\sqrt{2}}\right)}. \quad (20)$$

Trapezoid

A quadrilateral with two sides parallel. The trapezoid is equivalent to the British definition of trapezium. The trapezoid depicted has central median

$$m = \tfrac{1}{2}(a+b),$$

area

$$A = \tfrac{1}{2}(a+b)h = mh.$$

The centroid lies on the median m at a distance

$$x = \frac{b+2a}{3(a+b)}\,h$$

from the vertical position of the lower left vertex.

Traveler's Problem

HAMILTONIAN CIRCUIT

Traveling Salesman Constants

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let $L(n, d)$ be the smallest TOUR length for n points in a d-D HYPERCUBE. Then there exists a smallest constant $\alpha(d)$ such that for all optimal TOURS in the HYPERCUBE,

$$\limsup_{n\to\infty} \frac{L(n, d)}{n^{(d-1)/d}\sqrt{d}} \leq \alpha(d), \tag{1}$$

and a constant $\beta(d)$ such that for *almost* all optimal tours in the HYPERCUBE,

$$\lim_{n\to\infty} \frac{L(n, d)}{n^{(d-1)/d}\sqrt{d}} = \beta(d). \tag{2}$$

These constants satisfy the inequalities

$$0.44194 < \gamma_2 = \tfrac{5}{16}\sqrt{2} \leq \beta(2)$$
$$\leq \delta < 0.6508 < 0.75983 < 3^{-1/4} \leq \alpha(2)$$
$$\leq \phi < 0.98398 \quad (3)$$

$$0.37313 < \gamma_3 \leq \beta(3) \leq 12^{1/6}6^{-1/2} < 0.61772 < 0.64805$$
$$< 2^{1/6}3^{-1/2} \leq \alpha(3) \leq 0.90422 \tag{4}$$

$$0.34207 < \gamma_4 \leq \beta(4) \leq 12^{1/8}6^{-1/2} < 0.55696$$
$$< 0.59460 < 2^{-3/4} \leq \alpha(4) \leq 0.8364 \tag{5}$$

(Fejes Tóth 1940, Verblunsky 1951, Few 1955, Beardwood *et al.* 1959), where

$$\gamma_d \equiv \frac{\Gamma\left(3+\frac{1}{d}\right)\left[\Gamma\left(\frac{1}{2}d+1\right)\right]^{1/d}}{2\sqrt{\pi}(d^{1/2}+d^{-1/2})} \tag{6}$$

$\Gamma(z)$ is the GAMMA FUNCTION, δ is an expression involving STRUVE FUNCTIONS and NEUMANN FUNCTIONS,

$$\phi \equiv \frac{280(3-\sqrt{3})}{840-280\sqrt{3}+4\sqrt{5}-\sqrt{10}} \tag{7}$$

(Karloff 1989), and

$$\psi \equiv \tfrac{1}{2}\,3^{-2/3}(4+\ln 3)^{2/3} \tag{8}$$

(Goddyn 1990). In the LIMIT $d \to \infty$,

$$0.24197 < \lim_{d\to\infty} \gamma_d = \frac{1}{\sqrt{2\pi e}} \leq \liminf_{d\to\infty} \beta(d)$$
$$\leq \limsup_{d\to\infty} \beta(d) \leq \lim_{d\to\infty} 12^{1/(2d)}6^{-1/2} = \frac{1}{\sqrt{6}} < 0.40825 \tag{9}$$

and

$$0.24197 < \frac{1}{\sqrt{2\pi e}} \leq \lim_{d\to\infty} \alpha(d) \leq \frac{2(3-\sqrt{3})\theta}{\sqrt{2\pi e}}$$
$$< 0.4502, \tag{10}$$

where

$$\tfrac{1}{2} \leq \theta = \lim_{d\to\infty} [\theta(d)]^{1/d} \leq 0.6602, \tag{11}$$

and $\theta(d)$ is the best SPHERE PACKING density in d-D space (Goddyn 1990, Moran 1984, Kabatyanskii and Levenshtein 1978). Steele and Snyder (1989) proved that the limit $\alpha(d)$ exists.

Now consider the constant

$$\kappa \equiv \lim_{n\to\infty} \frac{L(n, 2)}{\sqrt{n}} = \beta(2)\sqrt{2}, \tag{12}$$

so

$$\tfrac{5}{8} = \gamma_2\sqrt{2} \leq \kappa \leq \delta\sqrt{2} < 0.9204. \tag{13}$$

The best current estimate is $\kappa \approx 0.7124$.

A certain self-avoiding SPACE-FILLING CURVE is an optimal TOUR through a set of n points, where n can be arbitrarily large. It has length

$$\lambda \equiv \lim_{m\to\infty} \frac{L_m}{\sqrt{n_m}} = \frac{4(1+2\sqrt{2})\sqrt{51}}{153} = 0.7147827\ldots, \tag{14}$$

where L_m is the length of the curve at the mth iteration and n_m is the point-set size (Moscato and Norman).

Traveling Salesman Problem

A problem in GRAPH THEORY requiring the most efficient (i.e., least total distance) HAMILTONIAN CIRCUIT a salesman can take through each of n cities. No general method of solution is known, and the problem is NP-HARD. Solution to the traveling salesman problem is implemented in *Mathematica* as `TravelingSalesman[g]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`).

Trawler Problem

A fast boat is overtaking a slower one when fog suddenly sets in. At this point, the boat being pursued changes course, but not speed. How should the pursuing vessel proceed in order to be sure of catching the other boat?

The amazing answer is that the pursuing boat should continue to the point where the slow boat would be if it had set its course directly for the pursuing boat when the fog set in. If the boat is not there, it should proceed in a SPIRAL whose origin is the point where the slow boat was when the fog set in. The SPIRAL can be constructed in such a way that the two boats will intersect before a complete turn is made.

Tree

A tree is a mathematical structure which can be viewed as either a GRAPH or as a DATA STRUCTURE. The two views are equivalent, since a tree DATA STRUCTURE contains not only a set of elements, but also connections between elements, giving a tree graph. Trees were first studied by Cayley (1857).

A tree graph is a set of straight line segments connected at their ends containing no closed loops (cycles). In other words, it is a simple, undirected, connected, acyclic graph (or, equivalently, a connected FOREST). A tree with n nodes has $n-1$ EDGES. Conversely, a CONNECTED GRAPH with n nodes and $n-1$ edges is a tree. All trees are BIPARTITE GRAPHS (Skiena 1990, p. 213).

The points of connection are known as FORKS and the segments as BRANCHES. Final segments and the nodes at their ends are called LEAVES. A tree with two BRANCHES at each FORK and with one or two LEAVES at the end of each branch is called a BINARY TREE.

Trees find applications in many diverse fields, including computer science, the enumeration of saturated hydrocarbons, the study of electrical circuits, etc. (Harary 1994, p. 4).

A tree T has either one node which is a GRAPH CENTER, in which case it is called a CENTRAL TREE, or two adjacent nodes which are GRAPH CENTERS , in which case it is called a BICENTRAL TREE (Harary 1994, p. 35).

When a special node is designated to turn a tree into a ROOTED TREE, it is called the ROOT (or sometimes "EVE.") In such a tree, each of the nodes which is one EDGE further away from a given node is called a CHILD, and nodes connected to the same node which are the same distance from the ROOT NODE are called SIBLINGS.

Note that two BRANCHES placed end-to-end are equivalent to a single BRANCH which means, for example, that there is only *one* tree of order 3. The number $t(n)$ of nonisomorphic trees of order $n = 1, 2, \ldots$ (where trees of orders 1, 2, ..., 6 are illustrated above), are 1, 1, 1, 2, 3, 6, 11, 23, 47, 106, 235, ... (Sloane's A000055).

Otter showed that

$$\lim_{n\to\infty} \frac{t(n) n^{5/2}}{\alpha^n} = \beta, \qquad (1)$$

(Otter 1948, Harary and Palmer 1973, Knuth 1969). Write the GENERATING FUNCTION for ROOTED TREES as

$$f(z) = \sum_{i=0}^{\infty} f_i z^i, \qquad (2)$$

where the COEFFICIENTS are

$$f_{i+1} = \frac{1}{i} \sum_{j=1}^{i} \left(\sum_{d|j} d f_d \right) f_{i-j+1}, \qquad (3)$$

with $f_0 = 0$ and $f_1 = 1$. Then

$$\alpha = 2.955765\ldots \qquad (4)$$

is the unique POSITIVE ROOT of

$$f\left(\frac{1}{x}\right) = 1, \qquad (5)$$

and

$$\beta = \frac{1}{\sqrt{2\pi}} \left[1 + \sum_{k=2}^{\infty} f'\left(\frac{1}{\alpha_k}\right) \frac{1}{\alpha_k} \right]^{3/2} = 0.5349485\ldots \qquad (6)$$

Tree Searching

N.B. A detailed online essay by S. Finch was the starting point for this entry.

In database structures, two quantities are generally of interest: the average number of comparisons required to

1. Find an existing random record, and
2. Insert a new random record into a data structure.

Some constants which arise in the theory of digital tree searching are

$$\alpha \equiv \sum_{k=1}^{\infty} \frac{1}{2^k - 1} = 1.6066951524\ldots \tag{1}$$

$$\beta \equiv \sum_{k=1}^{\infty} \frac{1}{(2^n - 1)^2} = 1.1373387363\ldots \tag{2}$$

Erdos (1948) proved that α is IRRATIONAL. The expected number of comparisons for a successful search is

$$E = \frac{\ln n}{\ln 2} + \frac{\gamma - 1}{\ln 2} - \alpha + \tfrac{3}{2} + \delta(n) + \mathcal{O}\left(n^{-1/2}\right) \tag{3}$$

$$\sim \lg n - 0.716644\ldots + \delta(n), \tag{4}$$

and for an unsuccessful search is

$$E = \frac{\ln n}{\ln 2} + \frac{\gamma}{\ln 2} - \alpha + \tfrac{1}{2} + \delta(n) + \mathcal{O}\left(n^{-1/2}\right) \tag{5}$$

$$\sim \lg n - 0.273948\ldots + \delta(n), \tag{6}$$

Here $\delta(n)$, $\epsilon(s)$, and $\rho(n)$ are small-amplitude periodic functions, and LG is the base 2 LOGARITHM. The VARIANCE for searching is

$$V \sim \frac{1}{12} + \frac{\pi^2 + 6}{6(\ln 2)^2} - \alpha - \beta + \epsilon(s)$$
$$\sim 2.844383\ldots + \epsilon(s) \tag{7}$$

and for inserting is

$$V \sim \frac{1}{12} + \frac{\pi^2}{6(\ln 2)^2} - \alpha - \beta + \epsilon(s)$$
$$\sim 0.763014\ldots + \epsilon(s). \tag{8}$$

The expected number of pairs of twin vacancies in a digital search tree is

$$\langle A_n \rangle = \left[\theta + 1 - \frac{1}{Q}\left(\frac{1}{\ln 2} + \alpha^2 - \alpha\right) + \rho(n)\right] n + \mathcal{O}\left(\sqrt{n}\right), \tag{9}$$

where

$$Q \equiv \prod_{k=1}^{\infty}\left(1 - \frac{1}{2^k}\right) = 0.2887880950\ldots \tag{10}$$

$$=\frac{1}{3}-\frac{1}{3\cdot 7}+\frac{1}{3\cdot 5\cdot 15}-\frac{1}{3\cdot 5\cdot 15\cdot 21}+\ldots \quad (11)$$

$$=\exp\left[-\sum_{n=1}^{\infty}\frac{1}{n(2^n-1)}\right] \quad (12)$$

$$=\sqrt{\frac{2\pi}{\ln 2}}\exp\left(\frac{\ln 2}{24}-\frac{\pi^2}{6\ln 2}\right)\prod_{n=1}^{\infty}\left[1-\exp\left(-\frac{4\pi^2 n}{\ln 2}\right)\right] \quad (13)$$

and

$$\theta=\sum_{k=1}^{\infty}\frac{k2^{k+1}}{1\cdot 3\cdot 7\cdot 16\cdots(2^k-1)}\sum_{j=1}^{k}\frac{1}{2^j-1}$$

$$=7.7431319855\ldots \quad (14)$$

(Flajolet and Sedgewick 1986). The linear COEFFICIENT of $\langle A_n\rangle$ fluctuates around

$$c=\theta+1-\frac{1}{Q}\left(\frac{1}{\ln 2}+\alpha^2-\alpha\right)=0.3720486812\ldots, \quad (15)$$

which can also be written

$$c=\frac{1}{\ln 2}$$

$$\times\int_0^{\infty}\frac{x}{1+x}\frac{dx}{(1+x)\left(1+\frac{1}{2}x\right)\left(1+\frac{1}{4}x\right)\left(1+\frac{1}{8}x\right)\cdots}. \quad (16)$$

(Flajolet and Richmond 1992).

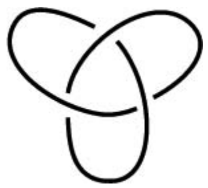
Tree-Planting Problem

ORCHARD-PLANTING PROBLEM



Trefoil Curve

The plane curve given by the equation

$$x^4+x^2y^2+y^4=x(x^2-y^2).$$

Trefoil Knot

The knot 03-001, also called the THREEFOIL KNOT, which is the unique PRIME KNOT of three crossings. It has BRAID WORD σ_1^3. The trefoil and its MIRROR IMAGE are not equivalent, as first proved by Dehn (1914). The trefoil has ALEXANDER POLYNOMIAL $-x^2+x-1$ and is a (3, 2)-TORUS KNOT. The BRACKET POLYNOMIAL can be computed as follows.

$$\langle L\rangle=A^3d^{2-1}+A^2Bd^{1-1}+A^2Bd^{1-1}+AB^2d^{2-1}$$
$$+A^2Bd^{1-1}+AB^2d^{2-1}+AB^2d^{2-1}+B^3d^{3-1}$$
$$=A^3d^1+3A^2Bd^0+3AB^2d^1+B^3d^2.$$

Plugging in

$$B=A^{-1}$$
$$d=-A^2-A^{-2}$$

gives

$$\langle L\rangle=A^{-7}-A^{-3}-A^5.$$

The normalized one-variable KAUFFMAN POLYNOMIAL X is then given by

$$X_L=\left(-A^3\right)^{-w(L)}\langle L\rangle=\left(-A^3\right)^{-3}\left(A^{-7}-A^{-3}-A^5\right)$$
$$=A^{-4}+A^{-12}-A^{-16},$$

where the WRITHE $w(L)=3$. The JONES POLYNOMIAL is therefore

$$V(t)=L\left(A=t^{-1/4}\right)=t+t^3-t^4=t\left(1+t^2-t^3\right).$$

Since $V(t^{-1}) \neq V(t)$, we have shown that the mirror images are not equivalent.

Trial

In statistics, a trial is a single performance of well-defined experiment (Papoulis 1984, p. 25), such as the flipping of a COIN, the generation of a RANDOM NUMBER, the dropping of a ball down the apex of a triangular lattice and having it fall into a single bin at the bottom, etc.

References

Papoulis, A. "Repeated Trials." Ch. 3 in *Probability, Random Variables, and Stochastic Processes, 2nd ed.* New York: McGraw-Hill, pp. 47–82, 1984.

Trial Division

A brute-force method of finding a DIVISOR of an INTEGER n by simply plugging in one or a set of INTEGERS and seeing if they DIVIDE n. Repeated application of trial division to obtain the complete PRIME FACTORIZATION of a number is called DIRECT SEARCH FACTORIZATION. An individual integer being tested is called a TRIAL DIVISOR.

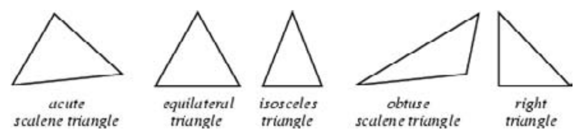
See also DIRECT SEARCH FACTORIZATION, DIVISION, PRIME FACTORIZATION

Trial Divisor

An INTEGER n which is tested to see if it divides a given number.

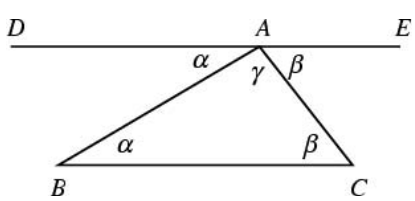
See also TRIAL DIVISION

Triamond



triamond

The unique 3-POLYIAMOND, illustrated above.

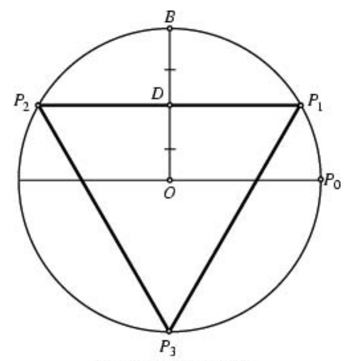


See also POLYIAMOND, TRAPEZOID

Triangle

A triangle is a 3-sided POLYGON sometimes (but not very commonly) called the TRIGON. All triangles are convex. An ACUTE TRIANGLE is a triangle whose three angles are all ACUTE. A triangle with all sides equal is called EQUILATERAL. A triangle with two sides equal is called ISOSCELES. A triangle having an OBTUSE ANGLE is called an OBTUSE TRIANGLE. A triangle with a RIGHT ANGLE is called RIGHT. A triangle with all sides a different length is called SCALENE.

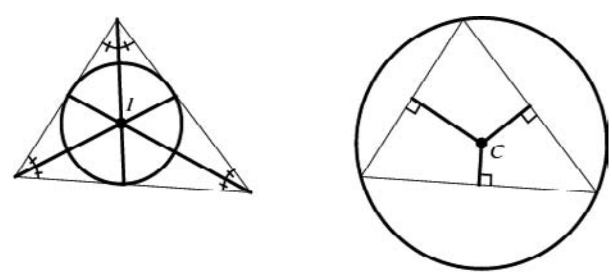
In 1816, while studying the BROCARD POINTS of a triangle, Crelle exclaimed, "It is indeed wonderful that so simple a figure as the triangle is so inexhaustible in properties. How many as yet unknown properties of other figures may there not be?" (Wells 1991, p. 21).



The sum of ANGLES in a triangle is $180° = \pi$ radians (at least in EUCLIDEAN GEOMETRY; this statement does *not* hold in NON-EUCLIDEAN GEOMETRY). This can be established as follows. Let $DAE \| BC$ (DAE be PARALLEL to BC) in the above diagram, then the angles α and β satisfy $\alpha = \angle DAB = \angle ABC$ and $\beta = \angle EAC = \angle ACB$, as indicated. Adding γ, it follows that

$$\alpha + \beta + \gamma = 180°, \qquad (1)$$

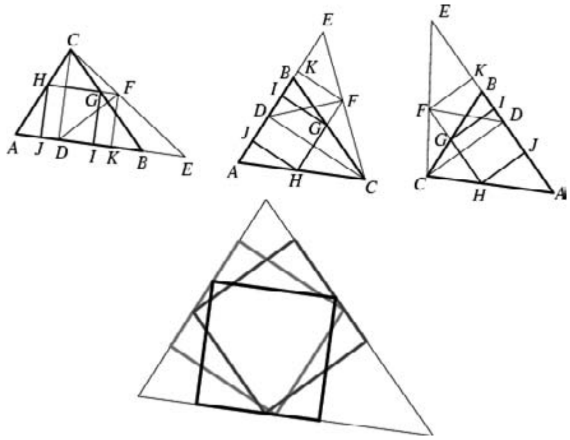
since the sum of angles for the line segment must equal two RIGHT ANGLES. Therefore, the sum of angles in the triangle is also 180°.



Let S stand for a triangle side and A for an angle, and let a set of Ss and As be concatenated such that adjacent letters correspond to adjacent sides and angles in a triangle. Triangles are uniquely determined by specifying three sides (SSS THEOREM), two angles and a side (AAS THEOREM), or two sides with an adjacent angle (SAS THEOREM). In each of these cases, the unknown three quantities (there are three sides and three angles total) can be uniquely determined. Other combinations of sides and angles do not uniquely determine a triangle: three angles specify a triangle only modulo a scale size (AAA THEOREM), and one angle and two sides not containing it may specify one, two, or no triangles (ASS THEOREM).

Allowable side lengths a, b, and c for a triangle are given by the set of inequalities $a > 0$, $b > 0$, $c > 0$, and $a + b > c$, $b + c > a$, $a + c > b$.

Equilateral Triangle

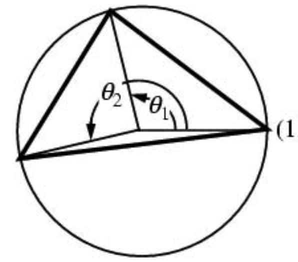


The STRAIGHTEDGE and COMPASS construction of the triangle can be accomplished as follows. In the above figure, take OP_0 as a RADIUS and draw $OB \perp OP_0$. Then bisect OB and construct $P_2P_1 \| OP_0$. Extending BO to locate P_3 then gives the EQUILATERAL TRIANGLE $\Delta P_1P_2P_3$. Another construction proceeds by drawing a CIRCLE of the desired RADIUS r centered at a point O. Choose a point B on the circle's CIRCUMFERENCE and draw another CIRCLE of radius r centered at B. The two circles intersect at two points, P_1 and P_2, and P_3 is the second point at which the line B_O intersects the first CIRCLE.

incircle *circumcircle*

In Proposition IV.4 of the *ELEMENTS*, Euclid showed how to inscribe a CIRCLE (the INCIRCLE) in a given

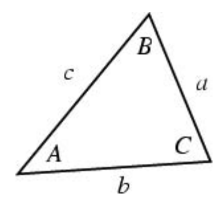
triangle by locating the INCENTER I as the point of intersection of ANGLE BISECTORS. In Proposition IV.5, he showed how to circumscribe a CIRCLE (the CIRCUMCIRCLE) about a given triangle by locating the CIRCUMCENTER O as the point of intersection of the PERPENDICULAR BISECTORS. unlike a general POLYGON with $n \geq 4$ sides, a triangle always has both a CIRCUMCIRCLE and an INCIRCLE. such polygons are called BICENTRIC POLYGONS.



Casey (1888, pp. 10–11) illustrates how to inscribe a SQUARE in an arbitrary triangle ΔABC. Construct the PERPENDICULAR $CD \perp AB$ and the line segment $BE = AD$. Bisect $\angle BDC$, and let F be the intersection of the bisector with BC. Then draw FK and FH through F, perpendicular to and parallel to AB, respectively. Let G be the intersection of FH and BC, and then construct FK and HJ through F and H perpendicular to AB. Then $\square GHJI$ is an inscribed SQUARE. Permuting the order in which the vertices are taken gives an additional two congruent squares. These squares, however, are not necessarily the *largest* inscribed squares. CALABI'S TRIANGLE is the only triangle (besides the EQUILATERAL TRIANGLE) for which the largest inscribed SQUARE can be inscribed in three different ways.

If the coordinates of the triangle VERTICES are given by (x_i, y_j) where $i = 1$ 2, 3, then the *signed* AREA Δ is given by the DETERMINANT

$$\Delta = \frac{1}{2!}\begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}, \tag{2}$$



so the actual area is obtained by taking the ABSOLUTE VALUE of (2). If the triangle is embedded in three-dimensional space with the coordinates of the VERTICES given by (x_i, x_j, z_i), where $i = 1, 2, 3$, then

$$\Delta = \frac{1}{2}\sqrt{\begin{vmatrix} y_1 & z_1 & 1 \\ y_2 & z_2 & 1 \\ y_3 & z_3 & 1 \end{vmatrix}^2 + \begin{vmatrix} z_1 & x_1 & 1 \\ z_2 & x_2 & 1 \\ z_3 & x_3 & 1 \end{vmatrix}^2 + \begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}^2}. \tag{3}$$

In the above figure, let the CIRCUMCIRCLE passing through a triangle's VERTICES have RADIUS r, and denote the CENTRAL ANGLES from the first point to the second θ_1, and to the third point by θ_2. Then the AREA of the triangle is given by

$$\Delta = 2r^2\left|\sin\left(\tfrac{1}{2}\,\theta_1\right)\sin\left(\tfrac{1}{2}\,\theta_2\right)\sin\left[\tfrac{1}{2}(\theta_1 - \theta_2)\right]\right|. \tag{4}$$

If a triangle has sides a, b, c, call the angles opposite these sides A, B, and C, respectively. Also define the SEMIPERIMETER s as HALF the PERIMETER:

$$s \equiv \tfrac{1}{2}\,p = \tfrac{1}{2}(a + b + c). \tag{5}$$

The AREA of a triangle is then given by HERON'S FORMULA

$$\Delta = \sqrt{s(s-a)(s-b)(s-c)}, \tag{6}$$

as well by the FORMULAS

$$\Delta = \tfrac{1}{4}\sqrt{(a+b+c)(b+c-a)(c+a-b)(a+b-c)} \tag{7}$$

$$= \tfrac{1}{4}\sqrt{2(a^2b^2 + a^2c^2 + b^2c^2) - (a^4 + b^4 + c^4)} \tag{8}$$

$$= \tfrac{1}{4}\sqrt{\left[(a+b)^2 - c^2\right]\left[c^2 - (a-b)^2\right]} \tag{9}$$

$$= \tfrac{1}{4}\sqrt{p(p-2a)(p-2b)(p-2c)}, \tag{10}$$

$$= 2R^2 \sin A \sin B \sin C \tag{11}$$

$$= \frac{abc}{4R} = rs \tag{12}$$

$$= \tfrac{1}{2}\,ah_a \tag{13}$$

$$= \tfrac{1}{2}\,bc \sin A. \tag{14}$$

In the above formulas, h_i is the ALTITUDE on side i, R is the CIRCUMRADIUS, and r is the INRADIUS (Johnson 1929, p. 11). A triangle with sides a, b, and c can be constructed by selecting vertices (0, 0), $(a,\ 0)$, and $(x,$

y), then solving

$$x^2 + y^2 = b^2 \tag{15}$$

$$(x-a)^2 + y^2 = c^2 \tag{16}$$

simultaneously to obtain

$$x = \frac{a^2 + b^2 - c^2}{2a} \tag{17}$$

$$y = \pm \frac{\sqrt{(-a+b+c)(a-b-c)(a-b+c)(a+b+c)}}{2a}. \tag{18}$$

Expressing the side lengths a, b, and c in terms of the radii a', b', and c' of the mutually TANGENT CIRCLES centered on the TRIANGLE vertices (which define the SODDY CIRCLES),

$$a = b' + c' \tag{19}$$

$$b = a' + c' \tag{20}$$

$$c = a' + b', \tag{21}$$

gives the particularly pretty form

$$\Delta = \sqrt{a'b'c'(a'+b'+c')}. \tag{22}$$

For additional FORMULAS, see Beyer (1987) and Baker (1884), who gives 110 FORMULAS for the AREA of a triangle.

The ANGLES of a triangle satisfy

$$\cot A = \frac{b^2 + c^2 - a^2}{4\Delta} \tag{23}$$

where Δ is the AREA (Johnson 1929, p. 11, with missing squared symbol added). This gives the pretty identity

$$\cot A + \cot B + \cot C = \frac{a^2 + b^2 + c^2}{4\Delta}. \tag{24}$$

In addition,

$$\tan A + \tan B + \tan C = \tan A \tan B \tan C \tag{25}$$

(F.J. n.d., p. 206; Borchardt and Perrott 1930) and

$$\cot B \cot C + \cot C \cot A + \cot A \cot B = 1 \tag{26}$$

$$\begin{aligned} &\tan A \cot B \cot C + \tan B \cot C \cot A \\ &\quad + \tan C \cot A \cot B \\ &= \tan A + \tan B + \tan C \\ &+ 2(\cot A + \cot B + \cot C) \end{aligned} \tag{27}$$

(Siddons and Hughes 1929).

Let a triangle have ANGLES A, B, and C. Then

$$\sin A \sin B \sin C \le kABC, \tag{28}$$

where

$$k = \left(\frac{3\sqrt{3}}{2\pi}\right)^3 \tag{29}$$

(Abi-Khuzam 1974, Le Lionnais 1983). This can be used to prove that

$$8\omega^3 < ABC, \tag{30}$$

where ω is the BROCARD ANGLE. Other inequalities include

$$\sin A + \sin B + \sin C \le \tfrac{3}{2}\sqrt{3} \tag{31}$$

$$1 \le \cos A + \cos B + \cos C \le \tfrac{3}{2} \tag{32}$$

$$\sin\left(\tfrac{1}{2}A\right)\sin\left(\tfrac{1}{2}B\right)\sin\left(\tfrac{1}{2}C\right) \le \tfrac{1}{8} \tag{33}$$

$$\tan\left(\tfrac{1}{2}A\right) + \tan\left(\tfrac{1}{2}B\right) + \tan\left(\tfrac{1}{2}C\right) \ge \sqrt{3} \tag{34}$$

$$\cot A \cot B \cot C \le \tfrac{1}{9}\sqrt{3} \tag{35}$$

$$\cot A + \cot B + \cot C \ge \sqrt{3} \tag{36}$$

$$\frac{\sin A \sin B \sin C}{\cot A + \cot B + \cot C} \le \tfrac{3}{8} \tag{37}$$

$$\frac{\tan\left(\tfrac{1}{2}A\right) + \tan\left(\tfrac{1}{2}B\right) + \tan\left(\tfrac{1}{2}C\right)}{\tan\left(\tfrac{1}{2}A\right)\tan\left(\tfrac{1}{2}B\right)\tan\left(\tfrac{1}{2}C\right)} \ge 9 \tag{38}$$

$$\begin{aligned} &\cos\left(\tfrac{1}{2}A\right)\cos\left(\tfrac{1}{2}B\right)\cos\left(\tfrac{1}{2}C\right) \ge \sin A \sin B \sin C \\ &\ge \sin(2A)\sin(2B)\sin(2C) \end{aligned} \tag{39}$$

$$2 \le \cos^2\left(\tfrac{1}{2}A\right) + \cos^2\left(\tfrac{1}{2}B\right) + \cos^2\left(\tfrac{1}{2}C\right) \le \tfrac{9}{4} \tag{40}$$

$$\begin{aligned} &\cot\left(\tfrac{1}{2}A\right)\cot\left(\tfrac{1}{2}B\right) + \cot\left(\tfrac{1}{2}B\right)\cot\left(\tfrac{1}{2}C\right) \\ &+ \cot\left(\tfrac{1}{2}C\right)\cot\left(\tfrac{1}{2}A\right) \ge 9 \end{aligned} \tag{41}$$

(Siddons and Hughes 1929, p. 283), and

$$\frac{\sin A + \sin B + \sin C}{\cot A + \cot B + \cot C} \le \frac{3}{2} \tag{42}$$

(Weisstein).

TRIGONOMETRIC FUNCTIONS of half angles can be expressed in terms of the triangle sides:

$$\cos\left(\tfrac{1}{2}A\right) = \sqrt{\frac{s(s-a)}{bc}} \tag{43}$$

$$\sin\left(\tfrac{1}{2}A\right) = \sqrt{\frac{(s-b)(s-c)}{bc}} \tag{44}$$

$$\tan\left(\tfrac{1}{2}A\right) = \sqrt{\frac{(s-b)(s-c)}{s(s-a)}}, \tag{45}$$

where s is the SEMIPERIMETER.

The number of different triangles which have INTEGRAL sides and PERIMETER n is

$$T(n) = P_3(n) - \sum_{1 \le i \le \lfloor n/2 \rfloor} P_2(j)$$

$$= \left[\frac{n^2}{12}\right] - \left\lfloor \frac{n}{4} \right\rfloor \left\lfloor \frac{n+2}{4} \right\rfloor$$

$$= \begin{cases} \left[\dfrac{n^2}{48}\right] & \text{for } n \text{ even} \\ \left[\dfrac{(n+3)^2}{48}\right] & \text{for } n \text{ odd}, \end{cases} \tag{46}$$

where P_2 and P_3 are PARTITION FUNCTIONS P, $[x]$ is the NINT function, and $\lfloor x \rfloor$ is the FLOOR FUNCTION (Jordan *et al.* 1979, Andrews 1979, Honsberger 1985). The values of $T(n)$ for $n = 1, 2, ...$ are 0, 0, 1, 0, 1, 1, 2, 1, 3, 2, 4, 3, 5, 4, 7, 5, 8, 7, 10, 8, 12, 10, 14, 12, 16, ... (Sloane's A005044), which is also ALCUIN'S SEQUENCE padded with two initial 0s. $T(n)$ also satisfies

$$T(2n) = T(2n-3) = P_3(n). \tag{47}$$

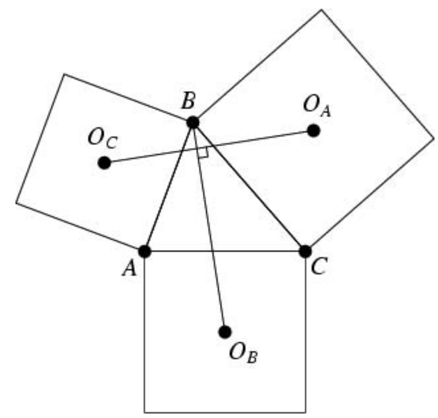
It is not known if a triangle with INTEGER sides, MEDIANS, and AREA exists (although there are incorrect PROOFS of the impossibility in the literature). However, R. L. Rathbun, A. Kemnitz, and R. H. Buchholz have shown that there are infinitely many triangles with RATIONAL sides (HERONIAN TRIANGLES) with *two* RATIONAL MEDIANS (Guy 1994).

In the following paragraph, assume the specified sides and angles are adjacent to each other. Specifying three ANGLES does not uniquely define a triangle, but any two triangles with the same ANGLES are similar (the AAA THEOREM). Specifying two ANGLES A and B and a side a uniquely determines a triangle with AREA

$$\Delta = \frac{a^2 \sin B \sin C}{2 \sin A} = \frac{a^2 \sin B \sin(\pi - A - B)}{2 \sin A} \tag{48}$$

(the AAS THEOREM). Specifying an ANGLE A, a side c, and an ANGLE B uniquely specifies a triangle with AREA

$$\Delta = \frac{c^2}{2(\cot A + \cot B)} \tag{49}$$



(the ASA THEOREM). Given a triangle with two sides, a the smaller and c the larger, and one known ANGLE A, ACUTE and opposite a, if $\sin A < a/c$, there are two possible triangles. If $\sin A = a/c$, there is one possible triangle. If $\sin A > a/c$, there are no possible triangles. This is the ASS THEOREM. Let a be the base length and h be the height. Then

$$\Delta = \tfrac{1}{2} ah = \tfrac{1}{2} ac \sin B \tag{50}$$

(the SAS THEOREM). Finally, if all three sides are specified, a unique triangle is determined with AREA given by HERON'S FORMULA or by

$$\Delta = \frac{abc}{4R}, \tag{51}$$

where R is the CIRCUMRADIUS. This is the SSS THEOREM.

If squares are erected externally on the sides of a triangle as illustrated above, then $BO_B \perp O_C O_A$, and

$$\overline{BO_B} = \overline{O_C O_A} \tag{52}$$

(Coxeter and Greitzer 1967, pp. 96–97).

Dividing the sides of a triangle in a constant ratio $r < 1/2$ and then drawing lines parallel to the adjacent sides passing through each of these points gives line segments which intersect each other and one of the medians in three places. If $r > 1/2$, then the extensions of the side parallels intersect the extensions of the medians.

The medians bisect the area of a triangle, as do the side parallels with ratio $1 + \sqrt{2}$. The envelope of the lines which bisect the area a triangle forms three hyperbolic arcs. The envelope is somewhat more complicated, however, for lines dividing the area of a triangle into a constant but unequal ratio (Dunn and Petty 1972, Ball 1980, Wells 1991).

There are four CIRCLES which are tangent to the sides of a triangle, one internal and the rest external. Their centers are the points of intersection of the ANGLE BISECTORS of the triangle.

Any triangle can be positioned such that its shadow under an orthogonal projection is EQUILATERAL.

Triangle Arcs

In the above figure, let ΔABC be a RIGHT TRIANGLE, arcs AP and AQ be segments of CIRCLES centered at C and B respectively, and define

$$a = BC \tag{1}$$

$$b = CA = CP \tag{2}$$

$$c = BA = BQ. \tag{3}$$

Then

$$PQ^2 = 2BP \cdot QC. \tag{4}$$

The figure also yields the algebraic identity

$$\left(b + c - \sqrt{b^2 + c^2}\right)^2 = 2\left(\sqrt{b^2 + c^2} - b\right)\left(\sqrt{b^2 + c^2} - c\right). \tag{5}$$

Triangle Center

A triangle center is a point whose TRILINEAR COORDINATES are defined in terms of the side lengths and angles of a TRIANGLE. The function giving the coordinates $\alpha : \beta : \gamma$ is called the TRIANGLE CENTER FUNCTION. The four ancient centers are the CENTROID, INCENTER, CIRCUMCENTER, and ORTHOCENTER. For a listing of these and other triangle centers, see Kimberling (1994).

A triangle center is said to be REGULAR IFF there is a TRIANGLE CENTER FUNCTION which is a POLYNOMIAL in Δ, a, b, and c (where Δ is the AREA of the TRIANGLE) such that the TRILINEAR COORDINATES of the center are

$$f(a, b, c) : f(b, c, a) : f(c, a, b).$$

A triangle center is said to be a MAJOR TRIANGLE CENTER if the TRIANGLE CENTER FUNCTION α is a function of ANGLE A alone, and therefore β and γ of B and C alone, respectively.

Triangle Center Function

A HOMOGENEOUS FUNCTION $f(a, b, c)$, i.e., a function f such that

$$f(ta, tb, tc) = t^n f(a, b, c),$$

which gives the TRILINEAR COORDINATES of a TRIANGLE CENTER as

$$\alpha : \beta : \gamma = f(a, b, c) : f(b, c, a) : f(c, a, b).$$

The variables may correspond to angles (A, B, C) or side lengths (a, b, c), since these can be interconverted using the LAW OF COSINES.

Triangle Coefficient

A function of three variables written $\Delta(abc) \equiv \Delta(a, b, c)$ and defined by

$$\Delta(abc) \equiv \sqrt{\frac{(a+b-c)!(a-b+c)!(-a+b+c)!}{(a+b+c+1)!}}.$$

Triangle Counting

Given rods of length 1, 2, ..., n, how many distinct triangles $T(n)$ can be made? Lengths for which

$$l_i = l_j + l_k$$

obviously do not give triangles, but all other combinations of three rods do. The answer is

$$T(n) = \begin{cases} \frac{1}{24} n(n-2)(2n-5) & \text{for } n \text{ even} \\ \frac{1}{24}(n-1)(n-3)(2n-1) & \text{for } n \text{ odd.} \end{cases}$$

The values for $n = 1, 2, \ldots$are 0, 0, 0, 1, 3, 7, 13, 22, 34, 50, ... (Sloane's A002623). Somewhat surprisingly, this sequence is also given by the GENERATING FUNCTION

$$f(x) = \frac{x^4}{(1-x)^3(1-x^2)} = x^4 + 3x^5 + 7x^6 + 13x^7 + \ldots.$$

Triangle Cubic Curve

A CUBIC CURVE on which 37 notable triangle centers lie.

References

Wells, D. *The Penguin Dictionary of Curious and Interesting Geometry.* London: Penguin, pp. 42–43, 1991.

Triangle Function

$$\Lambda(x) \equiv \begin{cases} 0 & |x| > 1 \\ 1 - |x| & |x| < 1 \end{cases} \tag{1}$$

$$= \Pi(x) * \Pi(x) \tag{2}$$

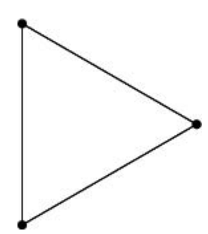
$$= \Pi(x) * H\left(x + \tfrac{1}{2}\right) - \Pi(x) * H\left(x - \tfrac{1}{2}\right), \tag{3}$$

where Π is the RECTANGLE FUNCTION and H is the HEAVISIDE STEP FUNCTION. An obvious generalization used as an APODIZATION FUNCTION goes by the name of the BARTLETT FUNCTION.

There is also a three-argument function known as the triangle function:

$$\lambda(x,\ y,\ z) \equiv x^2 + y^2 + z^2 - 2xy - 2xz - 2yz. \tag{4}$$

It follows that



$$\lambda(a^2,\ b^2,\ c^2) = (a+b+c)(a+b-c)(a-b+c)(a-b-c). \tag{5}$$

Triangle Interior

point outside triangle *point inside triangle*

To determine if a given point **v** lies in the interior of a given triangle, consider an individual vertex, denoted $\mathbf{v}_0$, and let $\mathbf{v}_1$ and $\mathbf{v}_2$ be the vectors from $\mathbf{v}_0$ to the other two vertices. Expressing the vector from $\mathbf{v}_0$ to **v** in terms of $\mathbf{v}_1$ and $\mathbf{v}_2$ then gives

$$\mathbf{v} = \mathbf{v}_0 + a\mathbf{v}_1 + b\mathbf{v}_2, \tag{1}$$

where a and b are constants. Solving for a and b gives

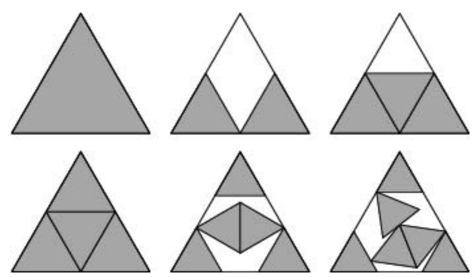
$$a = \frac{\det(\mathbf{v}\ \mathbf{v}_2) - \det(\mathbf{v}_0\ \mathbf{v}_2)}{\det(\mathbf{v}_1\ \mathbf{v}_2)} \tag{2}$$

$$b = -\frac{\det(\mathbf{v}\ \mathbf{v}_1) - \det(\mathbf{v}_0\ \mathbf{v}_1)}{\det(\mathbf{v}_1\ \mathbf{v}_2)}, \tag{3}$$

where

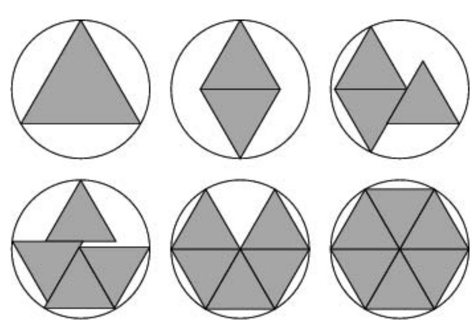
$$\det(\mathbf{u}\ \mathbf{v}) = \mathbf{u} \times \mathbf{v} = u_x v_y - u_y v_x \tag{4}$$

is the DETERMINANT of the matrix formed from the COLUMN VECTORS **u** and **v**. The point **v** will be "inside" the angle formed at $\mathbf{v}_0$ if $a,\ b > 0$, and so will be in the interior of the triangle if the corresponding $a,\ b > 0$ *for each* of the three vertices.



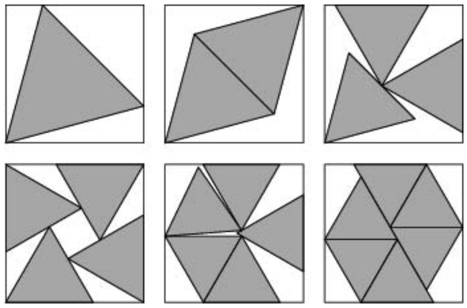
More generally, a point **v** is in the interior of a TRIANGLE if the CONVEX HULL of the three vertices plus the point **v** contains three points instead of four. This means the point **v** is inside the CONVEX HULL of the triangle, which is just the triangle itself.

See also CONVEX HULL, TRIANGLE

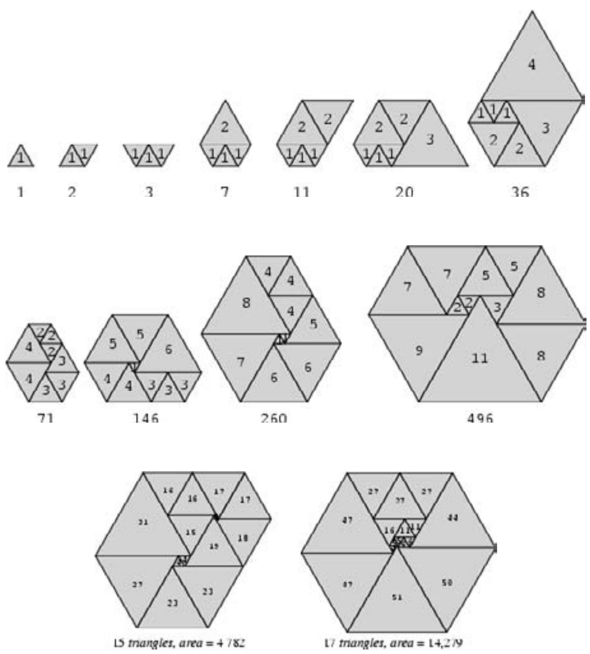


Triangle of Figurate Numbers

FIGURATE NUMBER TRIANGLE



Triangle Packing



The best known packings of equilateral triangles into an equilateral triangle are illustrated above for the first few cases (Friedman).

The best known packings of equilateral triangles into a circle are illustrated above for the first few cases (Friedman).

The best known packings of equilateral triangles into a square are illustrated above for the first few cases (Friedman).

Stewart (1998, 1999) considered the problem of finding the largest convex area that can be nontrivially tiled with equilateral triangles whose sides are integers for a given number of triangles and which have no overall common divisor. There is no upper limit if an arbitrary number of triangles are used. The following table gives the best known packings for small numbers of triangles.

n	max. area	reference	n	max. area	reference
1	1	Stewart 1997	11	495	Stewart 1997
2	2	Stewart 1997	12	860	Stewart 1998

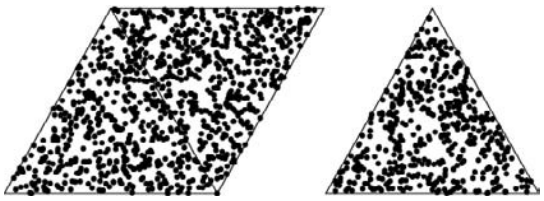
Triangle Point Picking



Given a triangle with one vertex at the origin and the others at positions $\mathbf{v}_1$ and $\mathbf{v}_2$, one might think that a random point inside the triangle would be given by

$$\mathbf{x} = a_1\mathbf{v}_1 + (1 - a_1)a_2\mathbf{v}_2,$$

where a_1 and a_2 are uniform variates in the interval $[0, 1]$. However, as can be seen in the plot above, this samples the triangle nonuniformly, concentrating

points in the $\mathbf{v}_1$ corner.

To pick points uniformly distributed inside the triangle, instead pick

$$\mathbf{x} = a_1 \mathbf{v}_1 + a_2 \mathbf{v}_2,$$

where a_1 and a_2 are uniform variates in the interval $[0, 1]$, which gives points uniformly distributed in a QUADRILATERAL (left figure). The points not in the TRIANGLE INTERIOR can then either be discarded, or transformed into the corresponding point inside the triangle (right figure).

Picking n points independently and uniformly from a triangle with unit area gives a CONVEX HULL with expected area of

$$A(n) = 1 - \frac{2}{n+1} \sum_{k=1}^{n} \frac{1}{k} = 1 - \frac{2H_n}{n+1},$$

where H_n is a HARMONIC NUMBER (Buchta 1984, 1986). This is a special case of SIMPLEX POINT PICKING.

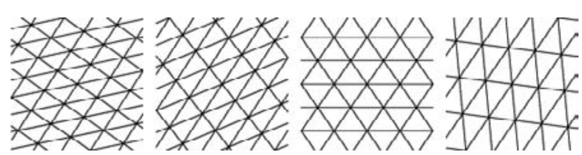
Triangle Squaring

Let CD be the ALTITUDE of a TRIANGLE ΔABC and let E be its MIDPOINT. Then

$$\text{area}(\Delta ABC) = \tfrac{1}{2} AB \cdot CD = AB \cdot DE,$$



and $\square ABFG$ can be SQUARED by RECTANGLE SQUARING. The general POLYGON can be treated by drawing diagonals, SQUARING the constituent TRIANGLES, and then combining the SQUARES together using the PYTHAGOREAN THEOREM.

Triangle Triangle Picking

The mean area of a triangle picked inside a triangle with unit area is $\bar{A} = 1/12$ (Pfiefer 1989). This was proposed by Watson (1865) and solved by Sylvester, and is a special case of the general formula for POLYGON TRIANGLE PICKING.

Triangular Dipyramid

The triangular (or TRIGONAL) dipyramid is one of the convex DELTAHEDRA, and JOHNSON SOLID J_{12}.

See also DELTAHEDRON, DIPYRAMID, HEXAHEDRON, JOHNSON SOLID, PENTAGONAL DIPYRAMID

Triangular Graph

The triangular graph with n nodes on a side is denoted $T(n)$. Tutte (1970) showed that the CHROMATIC POLYNOMIALS of planar triangular graphs possess a ROOT close to $\phi^2 = 2.618033\ldots$, where ϕ is the GOLDEN MEAN. More precisely, if n is the number of VERTICES of G, then

$$P_G(\phi^2) \leq \phi^{5-n}$$

(Le Lionnais 1983, p. 46). Every planar triangular graph possesses a VERTEX of degree 3, 4, or 5 (Le Lionnais 1983, pp. 49 and 53).

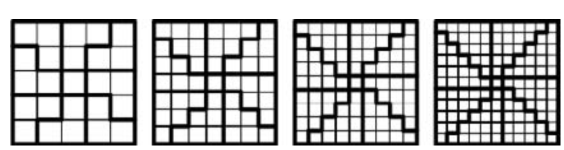
Triangular Number

A FIGURATE NUMBER OF THE FORM

$$T_n \equiv \tfrac{1}{2} n(n+1) = \binom{n+1}{2}, \tag{1}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT, obtained by building up regular triangles out of dots. The first few triangle numbers are 1, 3, 6, 10, 15, 21, ... (Sloane's A000217). The odd triangular numbers are given by 1, 3, 15, 21, 45, 55, ... (Sloane's A014493), while the even triangular numbers are 6, 10, 28, 36, 66, 78, ... (Sloane's A014494).

$T_4 = 10$ gives the number and arrangement of BOWLING pins, while $T_5 = 15$ gives the number and arrangement of balls in BILLIARDS. Triangular numbers satisfy the RECURRENCE RELATION



$$T_{n+1}^2 - T_n^2 = (n+1)^3, \tag{2}$$

as well as

$$3T_n + T_{n-1} = T_{2n} \tag{3}$$

$$3T_n + T_{n+1} = T_{2n+1} \tag{4}$$

$$1 + 3 + 5 + \ldots + (2n-1) = T_n + T_{n-1}. \tag{5}$$

In addition, the triangle numbers can be related to the square numbers by

$$(2n+1)^2 = 8T + 1 = T_{n-1} + 6T_n + T_{n+1} \tag{6}$$

(Conway and Guy 1996), as illustrated above (Wells 1991, p. 198). They have the ordinary GENERATING FUNCTION

$$f(x) = \frac{x}{(1-x)^3} = x + 3x^2 + 6x^3 + 10x^4 + 15x^5 + \ldots \tag{7}$$

and EXPONENTIAL GENERATING FUNCTION

$$\begin{aligned} g(x) &= \left(1+2x+\tfrac{1}{2}x^2\right)e^x \\ &= 1+3x+3x^2+\tfrac{5}{3}x^3+\tfrac{5}{8}x^4+\ldots \\ &= 1+3\,\frac{x}{1!}+6\,\frac{x^2}{2!}+10\,\frac{x^3}{3!}+15\,\frac{x^4}{4!}+\ldots \end{aligned} \quad (8)$$

(Sloane and Plouffe 1995, p. 9).

Every triangular number is also a HEXAGONAL NUMBER, since

$$\tfrac{1}{2}r(r+1) = \begin{cases} \left(\frac{r+1}{2}\right)\left[2\left(\frac{r+1}{2}\right)-1\right] & \text{for } r \text{ odd} \\ \left(-\frac{r}{2}\right)\left[2\left(-\frac{r}{2}\right)-1\right] & \text{for } r \text{ even.} \end{cases} \quad (9)$$

Also, every PENTAGONAL NUMBER is 1/3 of a triangular number. The sum of consecutive triangular numbers is a SQUARE NUMBER, since

$$\begin{aligned} T_r + T_{r-1} &= \tfrac{1}{2}r(r+1)+\tfrac{1}{2}(r-1)r \\ &= \tfrac{1}{2}r[(r+1)+(r-1)] = r^2. \end{aligned} \quad (10)$$

Interesting identities involving triangular numbers and SQUARE NUMBERS are

$$\sum_{k=1}^{2n-1}(-1)^{k+1}T_k = n^2 \quad (11)$$

$$T_n^2 = \sum_{k=1}^{n} k^3 = \tfrac{1}{4}n^2(n+1)^2 \quad (12)$$

$$\sum_{k=1,\,3,\,\ldots,\,q} k^3 = T_n \quad (13)$$

for q ODD and

$$n = \tfrac{1}{2}(q^2+2q-1). \quad (14)$$

Triangular numbers also unexpectedly appear in integrals involving the ABSOLUTE VALUE OF THE FORM

$$\int_0^1\int_0^1 |x-y|^n\,dx\,dy = \frac{2}{(n+1)(n+2)}. \quad (15)$$

All EVEN PERFECT NUMBERS are triangular T_p with PRIME p. Furthermore, every EVEN PERFECT NUMBER $P > 6$ is OF THE FORM

$$P = 1 + 9T_n = T_{3n+1}, \quad (16)$$

where T_n is a triangular number with $n = 8j+2$ (Eaton 1995, 1996). Therefore, the nested expression

$$9(9\cdots(9(9(9(9T_n+1)+1)+1)+1)\ldots+1)+1 \quad (17)$$

generates triangular numbers for any T_n. An INTEGER k is a triangular number IFF $8k+1$ is a SQUARE NUMBER > 1.

The numbers 1, 36, 1225, 41616, 1413721, 48024900, ... (Sloane's A001110) are SQUARE TRIANGULAR NUMBERS, i.e., numbers which are simultaneously triangular and SQUARE (Pietenpol 1962). The corresponding square roots are 1, 6, 35, 204, 1189, 6930, ... (Sloane's A001109), and the indices of the corresponding triangular numbers T_n are $n = 1$, 8, 49, 288, 1681, ... (Sloane's A001108).

Numbers which are simultaneously triangular and TETRAHEDRAL satisfy the BINOMIAL COEFFICIENT equation

$$T_n = \binom{n+1}{2} = \binom{m+2}{3} = Te_m, \quad (18)$$

the only solutions of which are

$$Te_3 = T_4 = 10 \quad (19)$$

$$Te_8 = T_{15} = 120 \quad (20)$$

$$Te_{20} = T_{55} = 1540 \quad (21)$$

$$Te_{34} = T_{119} = 7140 \quad (22)$$

(Guy 1994, p. 147).

The following table gives triangular numbers T_p having prime indices p.

T_n with prime indices	A034953	3, 6, 15, 28, 66, 91, 153, 190, 276, 435, 496, ...
odd T_n with prime indices	A034954	3, 15, 91, 153, 435, 703, 861, 1431, 1891, 2701, ...
even T_n with prime indices	A034955	6, 28, 66, 190, 276, 496, 946, 1128, 1770, 2278, ...

The smallest of two INTEGERS for which $n^3 - 13$ is four times a triangular number is 5 (Cesaro 1886; Le Lionnais 1983, p. 56). The only FIBONACCI NUMBERS which are triangular are 1, 3, 21, and 55 (Ming 1989), and the only PELL NUMBER which is triangular is 1 (McDaniel 1996). The BEAST NUMBER 666 is triangular, since

$$T_{6\cdot 6} = T_{36} = 666. \quad (23)$$

In fact, it is the largest REPDIGIT triangular number (Bellew and Weger 1975–76).

FERMAT'S POLYGONAL NUMBER THEOREM states that every POSITIVE INTEGER is a sum of *most* three TRIANGULAR NUMBERS, four SQUARE NUMBERS, five PENTAGONAL NUMBERS, and n n-POLYGONAL NUM-

BERS. Gauss proved the triangular case (Wells 1986, p. 47), and noted the event in his diary on July 10, 1796, with the notation

$$**E\Upsilon RHKA \quad num = \Delta + \Delta + \Delta. \qquad (24)$$

This case is equivalent to the statement that every number OF THE FORM $8m+3$ is a sum of three ODD SQUARES (Duke 1997). Dirichlet derived the number of ways in which an INTEGER m can be expressed as the sum of three triangular numbers (Duke 1997). The result is particularly simple for a PRIME OF THE FORM $8m+3$, in which case it is the number of squares mod $8m+3$ minus the number of nonsquares mod $8m+3$ in the INTERVAL $4m+1$ (Deligne 1973).

The only triangular numbers which are the PRODUCT of three consecutive INTEGERS are 6, 120, 210, 990, 185136, 258474216 (Sloane's A001219; Guy 1994, p. 148).

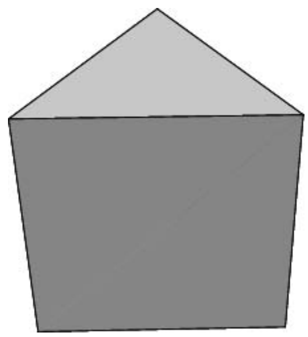
Triangular Orthobicupola

JOHNSON SOLID J_{27}, consisting of eight equilateral triangles and six squares. If a triangular orthobicupola is oriented with triangles on top and bottom, the two halves may be rotated one sixth of a turn with respect to each other to obtain the CUBOCTAHEDRON.



In hexagonal close packing, layers of spheres are packed so that spheres in alternating layers overlie one another. As in cubic close packing, each sphere is surrounded by 12 other spheres. Taking a collection of 13 such spheres gives the cluster illustrated above. Connecting the centers of the external 12 spheres gives J_{27} (Steinhaus 1983, pp. 203–205), which is therefore also a SPACE-FILLING POLYHEDRON.

Triangular Prism

A PRISM composed of triangular faces. The regular right triangular prism of unit edge length has SURFACE AREA and VOLUME

$$S = \tfrac{1}{2}(6 + \sqrt{3})$$

$$V = \tfrac{1}{4}\sqrt{3}.$$

See also PRISM

Triangular Pyramid

A PYRAMID having a triangular base. The SLANT HEIGHT of a regular triangular pyramid is a special case of the formula for a regular n-gonal PYRAMID with $n = 3$, given by

$$s = \sqrt{h^2 + \tfrac{1}{3}a^2}, \qquad (1)$$

where h is the height and a is the length of a side of the base. The TETRAHEDRON is a special case of the triangular pyramid.

See also PYRAMID, TETRAHEDRON

Triangular Square Number

SQUARE TRIANGULAR NUMBER

Triangular Symmetry Group

Given a TRIANGLE with angles $(\pi/p, \pi/q, \pi/r)$, the resulting symmetry GROUP is called a (p, q, r) triangle group (also known as a SPHERICAL TESSELLATION). In 3-D, such GROUPS must satisfy

$$\frac{1}{p} + \frac{1}{q} + \frac{1}{r} > 1,$$

and so the only solutions are $(2, 2, n)$, $(2, 3, 3)$, $(2, 3, 4)$, and $(2, 3, 5)$ (Ball and Coxeter 1987). The group $(2, 3, 6)$ gives rise to the semiregular planar TESSELLATIONS of types 1, 2, 5, and 7. The group $(2, 3, 7)$ gives hyperbolic tessellations.

Triangulation

Triangulation is the division of a surface or plane polygon into a set of TRIANGLES, usually with the restriction that each TRIANGLE side is entirely shared by two adjacent TRIANGLES. It was proved in 1925 that every surface has a triangulation, but it might require an infinite number of TRIANGLES and the proof is difficult (Francis and Weeks 1999). A surface with a finite number of triangles in its triangulation is called COMPACT.

Wickham-Jones (1994) gives an $\mathcal{O}(n^3)$ algorithm for triangulation ("otectomy"), and O'Rourke (1998, p. 47) sketches a method for improving this to $\mathcal{O}(n^2)$, as first done by Lennes (1911). Garey *et al.* (1978) gave an algorithmically straightforward $\mathcal{O}(n \ln n)$ method for triangulation, which was for many years believed optimal. However, Tarjan and van Wyk (1988) produced an $\mathcal{O}(n \lg \lg n)$ algorithm. This was followed by an unexpected result due to Chazelle (1991), who showed that an arbitrary SIMPLE POLYGON can be triangulated in $\mathcal{O}(n)$. However, according to Skiena (1997), "this algorithm is quite hopeless to implement."

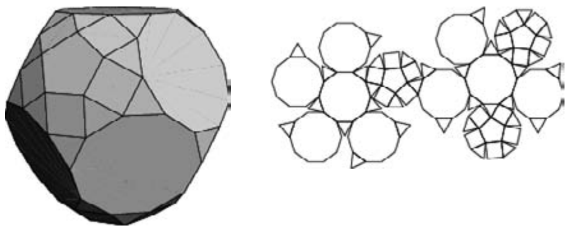
Triaugmented Triangular Prism

One of the convex DELTAHEDRA. It is composed of 14 equilateral triangles, and is JOHNSON SOLID J_{51}. The VERTICES are $(\pm 1/2, \pm 1/2, 0)$, $(0, 0, \sqrt{2}/2)$, $(0, \pm 1/2, -\sqrt{3}/2)$, $(\pm(1+\sqrt{6})/4, 0, -(\sqrt{2}+\sqrt{3})/4)$, where the x and z coordinates of the last are found by solving

$$x^2 + \left(\tfrac{1}{2}\right)^2 + \left(z + \sqrt{3}/2\right)^2 = 1^2 \tag{1}$$

$$\left(x - \tfrac{1}{2}\right)^2 + \left(\tfrac{1}{2}\right)^2 + z^2 = 1^2. \tag{2}$$



For a triaugmented triangular prism with unit side length, the SURFACE AREA and VOLUME are

$$S = \tfrac{7}{2}\sqrt{3} \tag{3}$$

$$V = \tfrac{1}{4}\left(2\sqrt{2} + \sqrt{3}\right). \tag{4}$$

Tribonacci Number

The tribonacci numbers are a generalization of the FIBONACCI NUMBERS defined by $T_1 = 1$, $T_2 = 1$, $T_3 = 2$, and the RECURRENCE RELATION

$$T_n = T_{n-1} + T_{n-2} + T_{n-3} \qquad (1)$$

for $n \geq 4$. The represent the $n = 3$ case of the FIBONACCI N-STEP NUMBERS. The first few terms are 1, 1, 2, 4, 7, 13, 24, 44, 81, 149, ... (Sloane's A000073). The ratio of adjacent terms tends to 1.83929, which is the REAL ROOT of $x^4 - 2x^3 + 1 = 0$. The Tribonacci numbers can also be computed using the GENERATING FUNCTION

$$\frac{1}{1 - z - z^2 - z^3} = 1 + z + 2z^2 + 4z^3 + 7z^4$$
$$+13z^5 + 24z^6 + 44z^7 + 81z^8 + 149z^9 + \ldots. \qquad (2)$$

An explicit FORMULA for T_n is also given by

$$\left[3\,\frac{\left\{\frac{1}{3}(19 + 3\sqrt{33})^{1/3} + \frac{1}{3}(19 - 3\sqrt{33})^{1/3} + \frac{1}{3}\right\}^n (586 + 102\sqrt{33})^{1/3}}{(586 + 102\sqrt{33})^{2/3} + 4 - 2(586 + 102\sqrt{33})^{1/3}}\right], \qquad (3)$$

where $[x]$ denotes the NINT function (Plouffe). The first part of a NUMERATOR is related to the REAL root of $x^3 - x^2 - x - 1$, but determination of the DENOMINATOR requires an application of the LLL ALGORITHM. The numbers increase asymptotically to

$$T_n \sim c^n, \qquad (4)$$

where

$$c = \left(\tfrac{19}{27} + \tfrac{1}{9}\sqrt{33}\right)^{1/3} + \tfrac{4}{9}\left(\tfrac{19}{27} + \tfrac{1}{9}\sqrt{33}\right)^{-1/3} + \tfrac{1}{3}$$
$$= 1.83928675521\ldots \qquad (5)$$

(Plouffe).

Trichotomy Law

Every REAL NUMBER is NEGATIVE, 0, or POSITIVE. The law is sometimes states as "For arbitrary real numbers x and y, exactly one of the relations $a < b$, $a = b$, $a > b$ holds" (Apostol 1967, p. 20).

Tricolorable

A projection of a LINK is tricolorable if each of the strands in the projection can be colored in one of three different colors such that, at each crossing, all three colors come together or only one does and at least two different colors are used. The TREFOIL KNOT and trivial 2-link are tricolorable, but the UNKNOT, WHITEHEAD LINK, and FIGURE-OF-EIGHT KNOT are not.

If the projection of a knot is tricolorable, then REIDEMEISTER MOVES on the knot preserve tricolorability, so either every projection of a knot is tricolorable or none is.

Tridiagonal Matrix

A MATRIX with NONZERO elements only on the diagonal and slots horizontally or vertically adjacent the diagonal (i.e., along the SUBDIAGONAL and SUPERDIAGONAL). A general 4×4 tridiagonal MATRIX has the form

$$\begin{bmatrix} a_{11} & a_{12} & 0 & 0 \\ a_{21} & a_{22} & a_{23} & 0 \\ 0 & a_{32} & a_{33} & a_{34} \\ 0 & 0 & a_{43} & a_{44} \end{bmatrix}.$$

Inversion of such a matrix requires only $\mathcal{O}(7n)$ (as opposed to $\mathcal{O}(n^3/3)$) arithmetic operations (Acton 1990, p. 332).

Trigonometric Addition Formulas

Angle addition FORMULAS express trigonometric functions of sums of angles $\alpha \pm \beta$ in terms of functions of α and β. The fundamental formulas of angle addition in trigonometry are given by

$$\sin(\alpha + \beta) = \sin\alpha \cos\beta + \sin\beta \cos\alpha \quad (1)$$

$$\sin(\alpha - \beta) = \sin\alpha \cos\beta - \sin\beta \cos\alpha \quad (2)$$

$$\cos(\alpha + \beta) = \cos\alpha \cos\beta - \sin\alpha \sin\beta \quad (3)$$

$$\cos(\alpha - \beta) = \cos\alpha \cos\beta + \sin\alpha \sin\beta \quad (4)$$

$$\tan(\alpha + \beta) = \frac{\tan\alpha + \tan\beta}{1 - \tan\alpha \tan\beta} \quad (5)$$

$$\tan(\alpha - \beta) = \frac{\tan\alpha - \tan\beta}{1 + \tan\alpha \tan\beta}. \quad (6)$$

The sine and cosine angle addition identities can be compactly summarized by the MATRIX EQUATION

$$\begin{bmatrix} \cos\alpha & \sin\alpha \\ -\sin\alpha & \cos\alpha \end{bmatrix} \begin{bmatrix} \cos\beta & \sin\beta \\ -\sin\beta & \cos\beta \end{bmatrix} = \begin{bmatrix} \cos(\alpha+\beta) & \sin(\alpha+\beta) \\ -\sin(\alpha+\beta) & \cos(\alpha+\beta) \end{bmatrix}. \quad (7)$$

These formulas can be simply derived using COMPLEX EXPONENTIALS and the EULER FORMULA as follows.

$$\cos(\alpha + \beta) + i \sin(\alpha + \beta) = e^{i(\alpha+\beta)} = e^{i\alpha}e^{i\beta}$$

$$= (\cos\alpha + i \sin\alpha)(\cos\beta + i \sin\beta)$$

$$= (\cos\alpha \cos\beta - \sin\alpha \sin\beta)$$

$$+ i(\sin\alpha \cos\beta + \cos\alpha \sin\beta). \quad (8)$$

Equating REAL and IMAGINARY PARTS then gives (1) and (3), and (2) and (4) follow immediately by substituting $-\beta$ for β.

Taking the ratio of (1) and (3) gives the tangent angle addition FORMULA

$$\tan(\alpha + \beta) \equiv \frac{\sin(\alpha + \beta)}{\cos(\alpha + \beta)} = \frac{\sin\alpha \cos\beta + \sin\beta \cos\alpha}{\cos\alpha \cos\beta - \sin\alpha \sin\beta}$$

$$= \frac{\frac{\sin\alpha}{\cos\alpha} + \frac{\sin\beta}{\cos\beta}}{1 - \frac{\sin\alpha \sin\beta}{\cos\alpha \cos\alpha\beta}} = \frac{\tan\alpha + \tan\beta}{1 - \tan\alpha \tan\beta}. \quad (9)$$

The DOUBLE-ANGLE FORMULAS are

$$\sin(2\alpha) = 2 \sin\alpha \cos\alpha \quad (10)$$

$$\cos(2\alpha) = \cos^2\alpha - \sin^2\alpha \quad (11)$$

$$= 2 \cos^2\alpha - 1 \quad (12)$$

$$= 1 - 2 \sin^2\alpha \quad (13)$$

$$\tan(2\alpha) = \frac{2\tan\alpha}{1 - \tan^2\alpha}. \qquad (14)$$

MULTIPLE-ANGLE FORMULAS are given by

$$\sin(nx) = \sum_{k=0}^{n} \binom{n}{k} \cos^k x \sin^{n-k} x \sin\left[\tfrac{1}{2}(n-k)\pi\right]. \qquad (15)$$

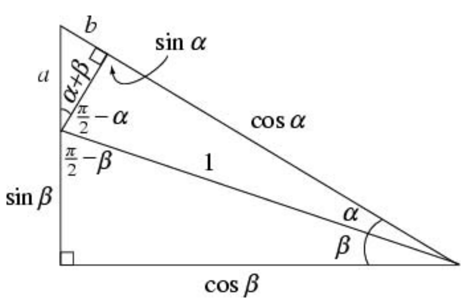
$$\cos(nx) = \sum_{k=0}^{n} \binom{n}{k} \cos^k x \sin^{n-k} x \cos\left[\tfrac{1}{2}(n-k)\pi\right], \qquad (16)$$

and can also be written using the RECURRENCE RELATIONS

$$\sin(nx) = 2\sin[(n-1)x]\cos x - \sin[(n-2)x] \qquad (17)$$

$$\cos(nx) = 2\cos[(n-1)x]\cos x - \cos[(n-2)x] \qquad (18)$$

$$\tan(nx) = \frac{\tan[(n-1)x] + \tan x}{1 - \tan[(n-1)x]\tan x}. \qquad (19)$$



SIMPSON'S FORMULAS are given by

$$\sin\alpha + \sin\beta = 2\sin\left(\frac{\alpha+\beta}{2}\right)\cos\left(\frac{\alpha-\beta}{2}\right) \qquad (20)$$

$$\sin\alpha - \sin\beta = 2\sin\left(\frac{\alpha-\beta}{2}\right)\cos\left(\frac{\alpha+\beta}{2}\right) \qquad (21)$$

$$\cos\alpha + \cos\beta = 2\cos\left(\frac{\alpha+\beta}{2}\right)\cos\left(\frac{\alpha-\beta}{2}\right) \qquad (22)$$

$$\cos\alpha - \cos\beta = -2\sin\left(\frac{\alpha-\beta}{2}\right)\sin\left(\frac{\alpha+\beta}{2}\right). \qquad (23)$$

The angle addition formulas can also be derived purely algebraically without the use of COMPLEX NUMBERS. Consider the small RIGHT TRIANGLE in the figure above, which gives

$$a = \frac{\sin\alpha}{\cos(\alpha+\beta)} \qquad (24)$$

$$b = \sin\alpha\tan(\alpha+\beta). \qquad (25)$$

Now, the usual trigonometric definitions applied to the large RIGHT TRIANGLE give

$$\sin(\alpha+\beta) = \frac{\sin\beta + a}{\cos\alpha + b}$$

$$= \frac{\sin\beta + \dfrac{\sin\alpha}{\cos(\alpha+\beta)}}{\cos\alpha + \sin\alpha\dfrac{\sin(\alpha+\beta)}{\cos(\alpha+\beta)}} \qquad (26)$$

$$\cos(\alpha+\beta) = \frac{\cos\beta}{\cos\alpha + b}$$

$$= \frac{\cos\beta}{\cos\alpha + \sin\alpha\dfrac{\sin(\alpha+\beta)}{\cos(\alpha+\beta)}}. \qquad (27)$$

Solving these two equations simultaneously for the variables $\sin(\alpha+\beta)$ and $\cos(\alpha+\beta)$ then immediately gives

$$\sin(\alpha+\beta) = \frac{\cos\alpha\sin\alpha + \cos\beta\sin\beta}{\cos\alpha\cos\beta + \sin\alpha\sin\beta} \qquad (28)$$

$$\cos(\alpha+\beta) = \frac{\cos^2\beta - \sin^2\alpha}{\cos\alpha\cos\beta + \sin\alpha\sin\beta}. \qquad (29)$$

These can be put into the familiar forms with the aid of the trigonometric identities

$$(\cos\alpha\cos\beta + \sin\alpha\sin\beta)(\cos\alpha\cos\beta + \sin\beta\cos\alpha)$$

$$= \cos\beta\sin\beta + \cos\alpha\sin\alpha \qquad (30)$$

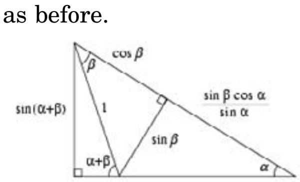
and

$$(\cos\alpha\cos\beta + \sin\alpha\sin\beta)(\cos\alpha\cos\beta - \sin\alpha\cos\beta)$$

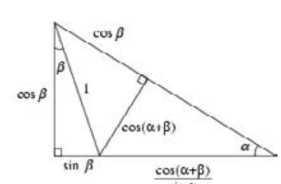
$$= \cos^2\alpha\cos^2\beta - \sin^2\alpha\sin^2\beta \qquad (31)$$

$$= 1 - \sin^2\alpha\sin^2\beta \qquad (32)$$

$$= \cos^2\alpha - \sin^2\beta \qquad (33)$$



$$= \cos^2\beta - \sin^2\alpha, \qquad (34)$$



which can be verified by direct multiplication. Plugging (30) into (28) and (34) into (29) then gives

$$\sin(\alpha+\beta) = \sin\alpha\cos\beta + \sin\beta\cos\alpha \qquad (35)$$

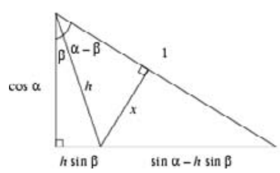
$$\cos(\alpha+\beta) = \cos\alpha\cos\beta - \sin\alpha\sin\beta, \qquad (36)$$

as before.

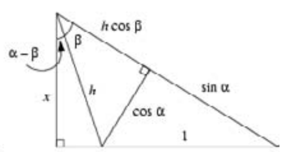
A similar proof due to Smiley and Smiley uses the left figure above to obtain

$$\sin\alpha = \frac{\sin(\alpha+\beta)}{\cos\beta + \dfrac{\sin\beta\cos\alpha}{\sin\alpha}}, \tag{37}$$

from which it follows that



$$\sin(\alpha+\beta) = \sin\alpha\cos\beta + \sin\beta\cos\alpha. \tag{38}$$



Similarly, from the right figure,

$$\frac{\sin\alpha}{\cos\alpha} = \frac{\cos\beta}{\sin\beta + \dfrac{\cos(\alpha+\beta)}{\sin\alpha}}, \tag{39}$$

so

$$\cos(\alpha+\beta) = \cos\alpha\cos\beta - \sin\alpha\sin\beta. \tag{40}$$

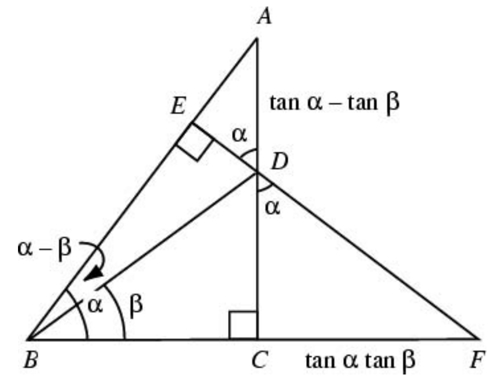
Similar diagrams can be used to prove the angle subtraction formulas (Smiley 1999, Smiley and Smiley). In the figure at left,

$$h = \frac{\cos\alpha}{\cos\beta} \tag{41}$$

$$\begin{aligned} x &= h\sin(\alpha-\beta) \\ &= (\sin\alpha - h\sin\beta)\cos\alpha, \end{aligned} \tag{42}$$

giving

$$\sin(\alpha-\beta) = \sin\alpha\cos\beta - \cos\alpha\sin\beta. \tag{43}$$



Similarly, in the figure at right,

$$h = \frac{\cos\alpha}{\sin\beta} \tag{44}$$

$$\begin{aligned} x &= h\cos(\alpha-\beta) \\ &= (\sin\alpha + h\cos\beta)\cos\alpha, \end{aligned} \tag{45}$$

giving

$$\cos(\alpha-\beta) = \cos\alpha\cos\beta + \sin\alpha\sin\beta. \tag{46}$$

A more complex diagram can be used to obtain a proof from the $\tan(\alpha-\beta)$ identity (Ren 1999). In the above figure, let $BF/BE = AD/DE$. Then

$$\tan(\alpha-\beta) = \frac{DE}{BE} = \frac{AD}{BF} = \frac{\tan\alpha - \tan\beta}{1+\tan\alpha\tan\beta}. \tag{47}$$

An interesting identity relating the sum and difference tangent formulas is given by

$$\begin{aligned} \frac{\tan(\alpha-\beta)}{\tan(\alpha+\beta)} &= \frac{\sin(\alpha-\beta)\cos(\alpha+\beta)}{\cos(\alpha-\beta)\sin(\alpha+\beta)} \\ &= \frac{(\sin\alpha\cos\beta - \sin\beta\cos\alpha)(\cos\alpha\cos\beta - \sin\alpha\sin\beta)}{(\cos\alpha\cos\beta + \sin\alpha\sin\beta)(\sin\alpha\cos\beta + \sin\beta\cos\alpha)} \\ &= \frac{\sin\alpha\cos\alpha - \sin\beta\cos\beta}{\sin\alpha\cos\alpha + \sin\beta\cos\beta}. \end{aligned} \tag{48}$$

Trigonometric Angles

The angles $n\pi/m$ (with m, n integers) for which the trigonometric function may be expressed in terms of finite root extraction of *real numbers* are limited to values of m which are precisely those which produce constructible polygons. Gauss showed these to be of the form

$$m = 2^k p_1 p_2 \cdots p_s,$$

where k is an INTEGER ≥ 0 and the p_i are distinct FERMAT PRIMES. The first few values are $m = 1, 2, 3, 4, 5, 6, 8, 10, 12, 15, 16, 17, 20, ...$ (Sloane's A003401). Where possible, analytic expressions for trigonometric functions with arguments of this form can be obtained using the *Mathematica* command `FunctionExpand`.

Although formulas for trigonometric functions may be found analytically for other m as well, the expressions involve ROOTS of COMPLEX NUMBERS obtained by solving a CUBIC, QUARTIC, or higher order equation. The cases $m = 7$ and $m = 9$ involve the CUBIC EQUATION and QUARTIC EQUATION, respectively. A partial table of the analytic values of SINE, COSINE, and TANGENT for arguments π/m is given below. Derivations of these formulas appear in the following entries.

x (°)	x (rad)	$\sin x$	$\cos x$	$\tan x$
0.0	0	0	1	0
15.0	$\frac{1}{12}\pi$	$\frac{1}{4}(\sqrt{6}-\sqrt{2})$	$\frac{1}{4}(\sqrt{6}+\sqrt{2})$	$2-\sqrt{3}$
18.0	$\frac{1}{10}\pi$	$\frac{1}{4}(\sqrt{5}-1)$	$\frac{1}{4}\sqrt{10+2\sqrt{5}}$	$\frac{1}{5}\sqrt{25-10\sqrt{5}}$
22.5	$\frac{1}{8}\pi$	$\frac{1}{2}\sqrt{2-\sqrt{2}}$	$\frac{1}{2}\sqrt{2+\sqrt{2}}$	$\sqrt{2}-1$
30.0	$\frac{1}{6}\pi$	$\frac{1}{2}$	$\frac{1}{2}\sqrt{3}$	$\frac{1}{3}\sqrt{3}$
36.0	$\frac{1}{5}\pi$	$\frac{1}{4}\sqrt{10-2\sqrt{5}}$	$\frac{1}{4}(1+\sqrt{5})$	$\sqrt{5-2\sqrt{5}}$
45.0	$\frac{1}{4}\pi$	$\frac{1}{2}\sqrt{2}$	$\frac{1}{2}\sqrt{2}$	1
60.0	$\frac{1}{3}\pi$	$\frac{1}{2}\sqrt{3}$	$\frac{1}{2}$	$\sqrt{3}$
90.0	$\frac{1}{2}\pi$	1	0	∞
180.0	π	0	-1	0

There is a nice mnemonic for remembering sines of common angles,

$$\sin(0°) = \tfrac{1}{2}\sqrt{0} \quad (1)$$

$$\sin(30°) = \tfrac{1}{2}\sqrt{1} \quad (2)$$

$$\sin(45°) = \tfrac{1}{2}\sqrt{2} \quad (3)$$

$$\sin(60°) = \tfrac{1}{2}\sqrt{3} \quad (4)$$

$$\sin(90°) = \tfrac{1}{2}\sqrt{4}. \quad (5)$$

Trigonometric Functions

The functions (also called the CIRCULAR FUNCTIONS) comprising TRIGONOMETRY: the COSECANT $\csc x$, COSINE $\cos x$, COTANGENT $\cot x$, SECANT $\sec x$, SINE $\sin x$, and TANGENT $\tan x$. The inverses of these functions are denoted $\csc^{-1} x$, $\cos^{-1} x$, $\cot^{-1} x$, $\sec^{-1} x$, $\sin^{-1} x$, and $\tan^{-1} x$. Note that the f^{-1} NOTATION here means INVERSE FUNCTION, *not* f to the -1 POWER.

See also DOUBLE-ANGLE FORMULAS, HALF-ANGLE FORMULAS, HYPERBOLIC FUNCTIONS, TRIGONOMETRY

Trigonometric Power Formulas

Power formulas include

$$\sin^2 x = \tfrac{1}{2}[1-\cos(2x)] \quad (1)$$

$$\sin^3 x = \tfrac{1}{4}[3\sin x - \sin(3x)] \quad (2)$$

$$\sin^4 x = \tfrac{1}{8}[3 - 4\cos(2x) + \cos(4x)] \quad (3)$$

and

$$\cos^2 x = \tfrac{1}{2}[1+\cos(2x)] \quad (4)$$

$$\cos^3 x = \tfrac{1}{4}[3\cos x + \cos(3x)] \quad (5)$$

$$\cos^4 x = \tfrac{1}{8}[3 + 4\cos(2x) + \cos(4x)] \quad (6)$$

(Beyer 1987, p. 140). Formulas of these types can also be given analytically as

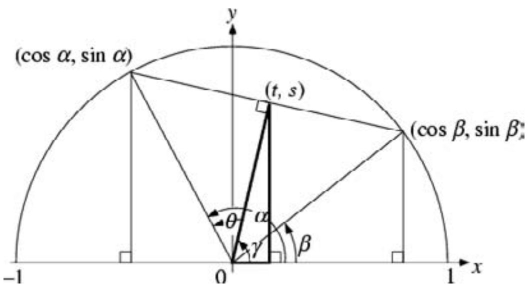
$$\sin^{2n} x = \frac{1}{2^{2n}}\binom{2n}{n} + \frac{(-1)^n}{2^{2n-1}}\sum_{k=0}^{n-1}(-1)^k\binom{2n}{k}\cos[2(n-k)x] \quad (7)$$

$$\sin^{2n+1} = \frac{(-1)^n}{4^n}\sum_{k=0}^{n}(-1)^k\binom{2n+1}{k}\sin[2n+1-2k)x] \quad (8)$$

$$\cos^{2n} x = \frac{1}{2^{2n}}\binom{2n}{n} + \frac{1}{2^{2n-1}}\sum_{k=0}^{n-1}\binom{2n}{k}\cos[2(n-k)x] \quad (9)$$

$$\cos^{2n+1} x = \frac{1}{4^n}\sum_{k=0}^{n}\binom{2n+1}{k}\cos[(2n+1-2k)x] \quad (10)$$

(Kogan), where $\binom{n}{m}$ is a BINOMIAL COEFFICIENT.



See also TRIGONOMETRY

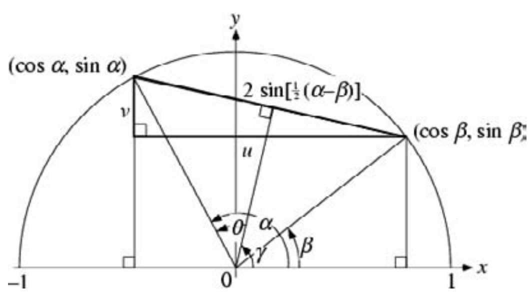
Trigonometric Product Formulas

Trigonometric product formulas for the sum of the cosines and sines of two angles can be derived using the above figure (Kung 1996). From the figure, define



$$\theta = \tfrac{1}{2}(\alpha - \beta) \tag{1}$$

$$\gamma = \tfrac{1}{2}(\alpha + \beta). \tag{2}$$

Then we have the identity

$$s = \tfrac{1}{2}(\sin\alpha + \sin\beta) = \cos\left[\tfrac{1}{2}(\alpha - \beta)\right]\sin\left[\tfrac{1}{2}(\alpha + \beta)\right] \tag{3}$$

$$t = \tfrac{1}{2}(\cos\alpha + \cos\beta) = \cos\left[\tfrac{1}{2}(\alpha - \beta)\right]\cos\left[\tfrac{1}{2}(\alpha + \beta)\right]. \tag{4}$$

Trigonometric product formulas for the difference of the cosines and sines of two angles can be derived using the similar figure illustrated above (Kung 1996). With θ and γ as previously defined, the above figure gives

$$u = \cos\beta - \cos\alpha = 2\sin\left[\tfrac{1}{2}(\alpha - \beta)\right]\sin\left[\tfrac{1}{2}(\alpha + \beta)\right] \tag{5}$$

$$v = \sin\alpha - \sin\beta = 2\sin\left[\tfrac{1}{2}(\alpha - \beta)\right]\cos\left[\tfrac{1}{2}(\alpha + \beta)\right]. \tag{6}$$

Trigonometric Series

Fourier Series

Trigonometric Series Formulas

Trigonometric identities which prove useful in the construction of map projections include

$$A\sin(2\phi) + B\sin(4\phi) + C\sin(6\phi) + D\sin(8\phi)$$
$$= \sin(2\phi)(A' + \cos(2\phi)(B' + \cos(2\phi)(C' + D'\cos(2\phi)))), \tag{1}$$

where

$$A' \equiv A - C \tag{2}$$

$$B' \equiv 2B - 4D \tag{3}$$

$$C' \equiv 4C \tag{4}$$

$$D' \equiv 8D. \tag{5}$$

$$A\sin\phi + B\sin(3\phi) + C\sin(5\phi) + D\sin(7\phi)$$
$$= \sin\phi\left(A' + \sin^2\phi\left(B' + \sin^2\phi\left(C' + D'\sin^2\phi\right)\right)\right), \tag{6}$$

where

$$A' \equiv A + 3B + 5C + 7D \tag{7}$$

$$B' \equiv -4B - 20C - 56D \tag{8}$$

$$C' \equiv 16C + 112D \tag{9}$$

$$D' \equiv -64D. \tag{10}$$

$$A + B\cos(2\phi) + C\cos(4\phi) + D\cos(6\phi) + E\cos(8\phi)$$
$$= A' + \cos(2\phi)(B' + \cos(2\phi)(C' + \cos(2\phi)$$
$$\times (D' + E'\cos(2\phi)))), \tag{11}$$

where

$$A' \equiv A - C + E \tag{12}$$

$$B' \equiv B - 3D \tag{13}$$

$$C' \equiv 2C - 8E \tag{14}$$

$$D' \equiv 4D \tag{15}$$

$$E' \equiv 8E \tag{16}$$

Trigonometric Substitution

INTEGRALS OF THE FORM

$$\int f(\cos\theta,\ \sin\theta)\,d\theta \tag{1}$$

can be solved by making the substitution $z = e^{i\theta}$ so that $dz = ie^{i\theta}\,d\theta$ and expressing

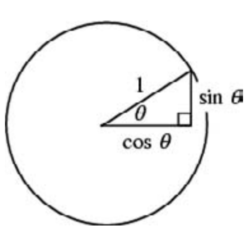
$$\cos\theta = \frac{e^{i\theta}+e^{-i\theta}}{2} = \frac{z+z^{-1}}{2} \tag{2}$$

$$\sin\theta = \frac{e^{i\theta}-e^{-i\theta}}{2i} = \frac{z-z^{-1}}{2i}. \tag{3}$$

The integral can then be solved by CONTOUR INTEGRATION.

Alternatively, making the substitution $t \equiv \tan(\theta/2)$ transforms (1) into

$$\int f\left(\frac{2t}{1+t^2}, \frac{1-t^2}{1+t^2}\right)\frac{2\,dt}{1+t^2}. \tag{4}$$



The following table gives trigonometric substitutions which can be used to transform integrals involving square roots.

Form	Substitution
$\sqrt{a^2-x^2}$	$x = a\sin\theta$
$\sqrt{a^2+x^2}$	$x = a\tan\theta$
$\sqrt{x^2-a^2}$	$x = a\sec\theta$

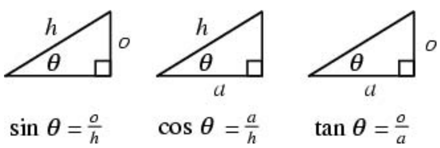
Trigonometry



The study of ANGLES and of the angular relationships of planar and 3-D figures is known as trigonometry. The TRIGONOMETRIC FUNCTIONS (also called the CIRCULAR FUNCTIONS) comprising trigonometry are the COSECANT $\csc x$, COSINE $\cos x$, COTANGENT $\cot x$, SECANT $\sec x$, SINE $\sin x$, and TANGENT $\tan x$. The inverses of these functions are denoted $\csc^{-1} x$, $\cos^{-1} x$, $\cot^{-1} x$, $\sec^{-1} x$, $\sin^{-1} x$, and $\tan^{-1} x$. Note that the f^{-1} NOTATION here means INVERSE FUNCTION, *not* f to the -1 POWER.

The trigonometric functions are most simply defined using the UNIT CIRCLE. Let θ be an ANGLE measured counterclockwise from the x-AXIS along an ARC of the CIRCLE. Then $\cos\theta$ is the horizontal coordinate of the ARC endpoint, and $\sin\theta$ is the vertical component. The RATIO $\sin\theta/\cos\theta$ is defined as $\tan\theta$. As a result of this definition, the trigonometric functions are periodic with period 2π, so

$$\mathrm{func}(2\pi n + \theta) = \mathrm{func}(\theta), \tag{1}$$

where n is an INTEGER and func is a trigonometric function.

A RIGHT TRIANGLE has three sides, which can be uniquely identified as the HYPOTENUSE, adjacent to a given angle θ, or opposite θ. A helpful mnemonic for remembering the definitions of the trigonometric functions is then given by "oh, ah, oh-ah,"

$$\sin\theta = \frac{\text{opposite}}{\text{hypotenuse}} \tag{2}$$

$$\cos\theta = \frac{\text{adjacent}}{\text{hypotenuse}} \tag{3}$$

$$\tan\theta = \frac{\text{opposite}}{\text{adjacent}}. \tag{4}$$

From the PYTHAGOREAN THEOREM,

$$\sin^2\theta + \cos^2\theta = 1. \tag{5}$$

Therefore, it is also true that

$$\tan^2\theta + 1 = \sec^2\theta \tag{6}$$

$$1 + \cot^2\theta = \csc^2\theta. \tag{7}$$

The trigonometric functions can be defined algebraically in terms of COMPLEX EXPONENTIALS (i.e., using the EULER FORMULA) as

$$\sin z \equiv \frac{e^{iz}-e^{-iz}}{2i} \tag{8}$$

$$\csc z \equiv \frac{1}{\sin z} = \frac{2i}{e^{iz}-e^{-iz}} \tag{9}$$

$$\cos z \equiv \frac{e^{iz}+e^{-iz}}{2} \tag{10}$$

$$\sec z \equiv \frac{1}{\cos z} = \frac{2}{e^{iz}+e^{-iz}} \tag{11}$$

$$\tan z \equiv \frac{\sin z}{\cos z} = \frac{e^{iz}-e^{-iz}}{i(e^{iz}+e^{-iz})} \tag{12}$$

$$\cot z \equiv \frac{1}{\tan z} = \frac{i(e^{iz} + e^{-iz})}{e^{iz} - e^{-iz}} = \frac{i(1 + e^{-2iz})}{1 - e^{-2iz}}. \quad (13)$$

Hybrid trigonometric product/sum formulas are

$$\sin(\alpha+\beta)\sin(\alpha-\beta) = \sin^2\alpha - \sin^2\beta = \cos^2\beta - \cos^2\alpha \quad (14)$$

$$\cos(\alpha+\beta)\cos(\alpha-\beta) = \cos^2\alpha - \sin^2\beta = \cos^2\beta - \sin^2\alpha. \quad (15)$$

OSBORNE'S RULE gives a prescription for converting trigonometric identities to analogous identities for HYPERBOLIC FUNCTIONS.

For IMAGINARY arguments,

$$\sin(iz) = i\sinh z \quad (16)$$

$$\cos(iz) = \cosh z. \quad (17)$$

For COMPLEX arguments,

$$\sin(x+iy) = \sin x\cosh y + i\cos x\sinh y \quad (18)$$

$$\cos(x+iy) = \cos x\cosh y - i\sin x\sinh y. \quad (19)$$

For the ABSOLUTE SQUARE of COMPLEX arguments $z = x + iy$,

$$|\sin(x+iy)|^2 = \sin^2 x + \sinh^2 y \quad (20)$$

$$|\cos(x+iy)|^2 = \cos^2 x + \sinh^2 y. \quad (21)$$

The MODULUS also satisfies the curious identity

$$|\sin(x+iy)| = |\sin x + \sin(iy)|. \quad (22)$$

The only functions satisfying identities of this form,

$$|f(x+iy)| = |f(x) + f(iy)| \quad (23)$$

are $f(z) = Az$, $f(z) = A\sin(bz)$, and $f(z) = A\sinh(bz)$ (Robinson 1957).

Trigonometry Values Pi

By the definition of the trigonometric functions,

$$\cos\pi = -1 \quad (1)$$

$$\cos\pi = \infty \quad (2)$$

$$\csc\pi = \infty \quad (3)$$

$$\sec\pi = -1 \quad (4)$$

$$\sin\pi = 0 \quad (5)$$

$$\tan\pi = 0. \quad (6)$$

Trigonometry Values Pi/2

By the definition of the trigonometric functions,

$$\cos\left(\frac{\pi}{2}\right) = 0 \quad (1)$$

$$\cot\left(\frac{\pi}{2}\right) = 0 \quad (2)$$

$$\csc\left(\frac{\pi}{2}\right) = 1 \quad (3)$$

$$\sec\left(\frac{\pi}{2}\right) = \infty \quad (4)$$

$$\sin\left(\frac{\pi}{2}\right)=1 \tag{5}$$

$$\tan\left(\frac{\pi}{2}\right)=\infty. \tag{6}$$

See also DIGON

Trigonometry Values Pi/3

$$\cos\left(\frac{\pi}{3}\right)=\tfrac{1}{2} \tag{1}$$

$$\cot\left(\frac{\pi}{3}\right)=\tfrac{1}{3}\sqrt{3} \tag{2}$$

$$\csc\left(\frac{\pi}{3}\right)=\tfrac{2}{3}\sqrt{3} \tag{3}$$

$$\sec\left(\frac{\pi}{3}\right)=2 \tag{4}$$

$$\sin\left(\frac{\pi}{3}\right)=\tfrac{1}{2}\sqrt{3} \tag{5}$$

$$\tan\left(\frac{\pi}{3}\right)=\sqrt{3}. \tag{6}$$

These formulas can be derived from knowledge of the TRIGONOMETRY VALUES FOR PI/6

$$\sin\left(\frac{\pi}{6}\right)=\tfrac{1}{2} \tag{7}$$

$$\cos\left(\frac{\pi}{6}\right)=\tfrac{1}{2}\sqrt{3} \tag{8}$$

together with the trigonometric identity

$$\sin(2\alpha)=2\sin\alpha\cos\alpha, \tag{9}$$

giving

$$\sin\left(\frac{\pi}{3}\right)=2\sin\left(\frac{\pi}{6}\right)\cos\left(\frac{\pi}{6}\right)=2\left(\tfrac{1}{2}\right)\left(\tfrac{1}{2}\sqrt{3}\right)=\tfrac{1}{2}\sqrt{3} \tag{10}$$

is obtained. Using the identity

$$\cos(2\alpha)=1-2\sin^2\alpha, \tag{11}$$

then gives

$$\cos\left(\frac{\pi}{3}\right)=1-2\sin^2\left(\frac{\pi}{6}\right)=1-2\left(\tfrac{1}{2}\right)^2=\tfrac{1}{2}. \tag{12}$$

See also EQUILATERAL TRIANGLE

Trigonometry Values Pi/4

$$\cos\left(\frac{\pi}{4}\right)=\tfrac{1}{2}\sqrt{2} \tag{1}$$

$$\cot\left(\frac{\pi}{4}\right)=1 \tag{2}$$

$$\csc\left(\frac{\pi}{4}\right)=\sqrt{2} \tag{3}$$

$$\sec\left(\frac{\pi}{4}\right)=\sqrt{2} \tag{4}$$

$$\sin\left(\frac{\pi}{4}\right)=\tfrac{1}{2}\sqrt{2} \tag{5}$$

$$\tan\left(\frac{\pi}{4}\right)=1. \tag{6}$$

For a RIGHT ISOSCELES TRIANGLE, symmetry requires that the angle at each VERTEX be given by

$$\tfrac{1}{2}\pi+2\alpha=\pi, \tag{7}$$

so $\alpha=\pi/4$. The sides are equal, so

$$\sin^2\alpha+\cos^2\alpha=2\sin^2\alpha=1. \tag{8}$$

Solving gives the above equations.

See also SQUARE

Trigonometry Values Pi/5

$$\cos\left(\frac{\pi}{5}\right)=\tfrac{1}{4}\left(1+\sqrt{5}\right) \tag{1}$$

$$\cos\left(\frac{2\pi}{5}\right)=\tfrac{1}{4}\left(-1+\sqrt{5}\right) \tag{2}$$

$$\cot\left(\frac{\pi}{5}\right)=\tfrac{1}{5}\sqrt{25+10\sqrt{5}} \tag{3}$$

$$\cot\left(\frac{2\pi}{5}\right)=\tfrac{1}{5}\sqrt{25-10\sqrt{5}} \tag{4}$$

$$\csc\left(\frac{\pi}{5}\right)=\tfrac{1}{5}\sqrt{50+10\sqrt{5}} \tag{5}$$

$$\csc\left(\frac{2\pi}{5}\right)=\tfrac{1}{5}\sqrt{50-10\sqrt{5}} \tag{6}$$

$$\sec\left(\frac{\pi}{5}\right)=\sqrt{5}-1 \tag{7}$$

$$\sec\left(\frac{2\pi}{5}\right) = 1 + \sqrt{5} \quad (8)$$

$$\sin\left(\frac{\pi}{5}\right) = \tfrac{1}{4}\sqrt{10 - 2\sqrt{5}} \quad (9)$$

$$\sin\left(\frac{2\pi}{5}\right) = \tfrac{1}{4}\sqrt{10 + 2\sqrt{5}} \quad (10)$$

$$\tan\left(\frac{\pi}{5}\right) = \sqrt{5 - 2\sqrt{5}} \quad (11)$$

$$\tan\left(\frac{2\pi}{5}\right) = \sqrt{5 + 2\sqrt{5}}. \quad (12)$$

These formulas can be derived using the identity

$$\sin(5\alpha) = 5 \sin \alpha - 20 \sin^3 \alpha + 16 \sin^5 \alpha. \quad (13)$$

Now, let $\alpha \equiv \pi/5$ and $x \equiv \sin \alpha$. Then

$$\sin \pi = 0 = 5x - 20x^3 + 16x^5 \quad (14)$$

$$16x^4 - 20x^2 + 5 = 0. \quad (15)$$

Solving the QUADRATIC EQUATION for x^2 gives

$$\sin^2\left(\frac{\pi}{5}\right) = x^2 = \frac{20 \pm \sqrt{(-20)^2 - 4 \cdot 16 \cdot 5}}{2 \cdot 16}$$

$$= \frac{20 \pm \sqrt{80}}{32} = \tfrac{1}{8}\left(5 \pm \sqrt{5}\right). \quad (16)$$

Now, $\sin(\pi/5)$ must be less than

$$\sin\left(\frac{\pi}{4}\right) = \tfrac{1}{2}\sqrt{2}, \quad (17)$$

so taking the MINUS SIGN and simplifying gives

$$\sin\left(\frac{\pi}{5}\right) = \sqrt{\frac{5 - \sqrt{5}}{8}} = \tfrac{1}{4}\sqrt{10 - 2\sqrt{5}}. \quad (18)$$

$\cos(\pi/5)$ can be computed from

$$\cos\left(\frac{\pi}{5}\right) = \sqrt{1 - \sin^2\left(\frac{\pi}{5}\right)} = \tfrac{1}{4}\left(1 + \sqrt{5}\right). \quad (19)$$

See also DODECAHEDRON, GOLDEN RATIO, ICOSAHEDRON, PENTAGON, PENTAGRAM

Trigonometry Values Pi/6

$$\cos\left(\frac{\pi}{6}\right) = \tfrac{1}{2}\sqrt{3} \quad (1)$$

$$\cot\left(\frac{\pi}{6}\right) = \sqrt{3} \quad (2)$$

$$\csc\left(\frac{\pi}{6}\right) = 2 \quad (3)$$

$$\sec\left(\frac{\pi}{6}\right) = \tfrac{2}{3}\sqrt{3} \quad (4)$$

$$\sin\left(\frac{\pi}{6}\right) = \tfrac{1}{2} \quad (5)$$

$$\tan\left(\frac{\pi}{6}\right) = \tfrac{1}{3}\sqrt{3}. \quad (6)$$

Given a RIGHT TRIANGLE with angles defined to be α and 2α, it must be true that

$$\alpha + 2\alpha + \tfrac{1}{2}\pi = \pi, \quad (7)$$

so $\alpha = \pi/6$. Define the hypotenuse to have length 1 and the side opposite α to have length x, then the side opposite 2α has length $\sqrt{1 - x^2}$. This gives $\sin \alpha \equiv x$ and

$$\sin(2\alpha) = \sqrt{1 - x^2}. \quad (8)$$

But

$$\sin(2\alpha) = 2 \sin \alpha \cos \alpha = 2x\sqrt{1 - x^2}, \quad (9)$$

so we have

$$\sqrt{1 - x^2} = 2x\sqrt{1 - x^2}. \quad (10)$$

This gives $2x = 1$, or

$$\sin\left(\frac{\pi}{6}\right) = \tfrac{1}{2}. \quad (11)$$

$\cos(\pi/6)$ is then computed from

$$\cos\left(\frac{\pi}{6}\right) = \sqrt{1 - \sin^2\left(\frac{\pi}{6}\right)} = \sqrt{1 - \left(\tfrac{1}{2}\right)^2} = \tfrac{1}{2}\sqrt{3}. \quad (12)$$

See also HEXAGON, HEXAGRAM

Trigonometry Values Pi/7

Trigonometric functions of $n\pi/7$ for n an integer cannot be expressed in terms of sums, products, and finite ROOT EXTRACTIONS on *real* rational numbers because 7 is not a FERMAT PRIME. This also means that the HEPTAGON is not a CONSTRUCTIBLE POLYGON.

However, exact expressions involving roots of *complex* numbers can still be derived using the trigonometric identity

$$\sin(n\alpha) = 2\sin[(n-1)\alpha]\cos\alpha - \sin[(n-2)\alpha]. \tag{1}$$

The case $n = 7$ gives

$$\begin{aligned}\sin(7\alpha) &= 2\sin(6\alpha)\cos\alpha - \sin(5\alpha)\\ &= 2(32\cos^5\alpha\sin\alpha - 32\cos^3\alpha\sin\alpha\\ &\quad +6\cos\alpha\sin\alpha)\cos\alpha\\ &\quad -(5\sin\alpha - 20\sin^3\alpha + 16\sin^5\alpha)\\ &= 64\cos^6\alpha\sin\alpha - 64\cos^4\alpha\sin\alpha + 12\cos^2\alpha\sin\alpha\\ &\quad -5\sin\alpha + 20(1-\cos^2\alpha)\sin\alpha\\ &\quad -16(1-2\cos^2\alpha+\cos^4\alpha)\sin\alpha\\ &= \sin\alpha(64\cos^6\alpha - 80\cos^4\alpha + 24\cos^2\alpha - 1).\end{aligned} \tag{2}$$

Rewrite this using the identity $\cos^2\alpha = 1 - \sin^2\alpha$,

$$\begin{aligned}\sin\left(\frac{\pi}{7}\right) &= \sin\alpha(7 - 56\sin^2\alpha + 112\sin^4\alpha - 64\sin^6\alpha)\\ &= -64\sin\alpha\left(\sin^6\alpha - \tfrac{112}{64}\sin^4\alpha + \tfrac{56}{64}\sin^2\alpha - \tfrac{7}{64}\right).\end{aligned} \tag{3}$$

Now, let $\alpha \equiv \pi/7$ and $x \equiv \sin^2\alpha$, then

$$\sin(\pi) = 0 = x^3 - \tfrac{7}{4}x^2 + \tfrac{7}{8}x - \tfrac{7}{64}, \tag{4}$$

which is a CUBIC EQUATION in x. The ROOTS are numerically found to be $x \approx 0.188255$, 0.611260, 0.950484. But $\sin\alpha = \sqrt{x}$, so these ROOTS correspond to $\sin\alpha \approx 0.4338$, $\sin(2\alpha) \approx 0.7817$, $\sin(3\alpha) \approx 0.9749$. By NEWTON'S RELATION

$$\prod_i r_i = -a_0 \tag{5}$$

we have

$$x_1x_2x_3 = \tfrac{7}{64}, \tag{6}$$

or

$$\sin\left(\frac{\pi}{7}\right)\sin\left(\frac{2\pi}{7}\right)\sin\left(\frac{3\pi}{7}\right) = \sqrt{\frac{7}{64}} = \tfrac{1}{8}\sqrt{7}. \tag{7}$$

Similarly,

$$\cos\left(\frac{\pi}{7}\right)\cos\left(\frac{2\pi}{7}\right)\cos\left(\frac{3\pi}{7}\right) = \frac{1}{8} \tag{8}$$

and

$$\cos^2\left(\frac{\pi}{7}\right) - \cos\left(\frac{\pi}{7}\right)\cos\left(\frac{2\pi}{7}\right) = \frac{1}{4} \tag{9}$$

(Bankoff and Garfunkel 1973).

The constants of the CUBIC EQUATION are given by

$$Q \equiv \tfrac{1}{9}(3a_1 - a_2^2) = \tfrac{1}{9}\left[3\cdot\tfrac{7}{8} - \left(-\tfrac{7}{4}\right)^2\right] = -\tfrac{7}{144} \tag{10}$$

$$\begin{aligned}R &\equiv \tfrac{1}{54}(9a_2a_1 - 2a_2^3 - 27a_0)\\ &= \tfrac{1}{54}\left[9\left(-\tfrac{7}{4}\right)\left(\tfrac{1}{7}8\right) - 2\left(-\tfrac{7}{4}\right)^3 - 27\left(-\tfrac{7}{64}\right)\right]\\ &= -f73456.\end{aligned} \tag{11}$$

The DISCRIMINANT is then

$$\begin{aligned}D &\equiv Q^3 + R^3 = -\tfrac{343}{2{,}985{,}984} + \tfrac{49}{11{,}943{,}936}\\ &= -\tfrac{49}{442{,}368} < 0,\end{aligned} \tag{12}$$

so there are three distinct REAL ROOTS. Finding the first one,

$$x = \sqrt{R + \sqrt{D}} + \sqrt{R - \sqrt{D}} - \tfrac{1}{3}a_2. \tag{13}$$

Writing

$$\sqrt{D} = 3^{-3/2}\,\tfrac{7}{128}\,i, \tag{14}$$

plugging in from above, and anticipating that the solution we have picked corresponds to $\sin(3\pi/7)$,

$$\begin{aligned}\sin\left(\frac{3\pi}{7}\right) &= \sqrt{x}\\ &= \sqrt{\sqrt{-\tfrac{7}{3456} + 3^{-3/2}\tfrac{7}{128}i} + \sqrt{-\tfrac{7}{3456} - 3^{-3/2}\tfrac{7}{128}i} - \tfrac{1}{3}(-\tfrac{7}{4})}\\ &= \sqrt{\sqrt{-\tfrac{7}{3456} + 3^{-3/2}\tfrac{7}{128}i} + \sqrt{-\tfrac{7}{3456} - 3^{-3/2}\tfrac{7}{128}i} + \tfrac{7}{12}}\\ &= \sqrt{\sqrt{\tfrac{7}{3456}(-1 + 3^{3/2}i)} - \sqrt{\tfrac{7}{3456}(1 + 3^{3/2}i)} + \tfrac{7}{12}}\end{aligned}$$

$$\tan\left(\frac{\pi}{8}\right)=\sqrt{2}-1 \quad (11)$$

$$\tan\left(\frac{3\pi}{8}\right)=1+\sqrt{2}. \quad (12)$$

$$\sin\left(\frac{\pi}{8}\right)=\sin\left(\frac{1}{2}\cdot\frac{\pi}{4}\right)=\sqrt{\frac{1}{2}\left(1-\cos\frac{\pi}{4}\right)}$$

$$=\sqrt{\tfrac{1}{2}\left(1-\tfrac{1}{2}\sqrt{2}\right)}=\tfrac{1}{2}\sqrt{2-\sqrt{2}}. \quad (13)$$

Now, checking to see if the SQUARE ROOT can be simplified gives

$$a^2-b^2c=2^2-1^2\cdot 2=4-2=2, \quad (14)$$

which is not a PERFECT SQUARE, so the above expression cannot be simplified. Similarly,

$$\cos\left(\frac{\pi}{8}\right)=\cos\left(\frac{1}{2}\,\frac{\pi}{4}\right)=\sqrt{\frac{1}{2}\left(1+\cos\frac{\pi}{4}\right)}$$

$$=\sqrt{\frac{1}{2}\left(1+\frac{\sqrt{2}}{3}\right)}=\tfrac{1}{2}\sqrt{2+\sqrt{2}} \quad (15)$$

$$\tan\left(\frac{\pi}{8}\right)=\sqrt{\frac{2-\sqrt{2}}{2+\sqrt{2}}}=\sqrt{\frac{\left(2-\sqrt{2}\right)^2}{4-2}}=\sqrt{\frac{4+2-4\sqrt{2}}{2}}$$

$$=\sqrt{\frac{6-4\sqrt{2}}{2}}=\sqrt{3-2\sqrt{2}}. \quad (16)$$

But

$$a^2-b^2c=3^2-2^2 2=9-8=1 \quad (17)$$

is a PERFECT SQUARE, so we can find

$$d=\tfrac{1}{2}(3\pm 1)=1,\ 2. \quad (18)$$

Rewrite the above as

$$\tan\left(\frac{\pi}{8}\right)=\sqrt{2}-1 \quad (19)$$

$$\cot\left(\frac{\pi}{8}\right)=\frac{1}{\sqrt{2}-1}=\frac{\sqrt{2}+1}{2-1}=\sqrt{2}+1. \quad (20)$$

See also OCTAGON

Trigonometry Values Pi/9

Trigonometric functions of $n\pi/9$ radians for n an integer not divisible by 3 (e.g., 40° and 80°) cannot be expressed in terms of sums, products, and finite ROOT EXTRACTIONS on RATIONAL NUMBERS because 9 is not a product of distinct FERMAT PRIMES. This also means that the regular NONAGON is not a CONSTRUCTIBLE POLYGON.

However, exact expressions involving roots of *complex* numbers can still be derived using the trigonometric identity

$$\sin(3\alpha)=3\sin\alpha-4\sin^3\alpha. \quad (1)$$

Let $\alpha\equiv\pi/9$ and $x\equiv\sin\alpha$. Then the above identity gives the CUBIC EQUATION

$$4x^3-3x+\tfrac{1}{2}\sqrt{3}=0 \quad (2)$$

$$x^3-\tfrac{3}{4}x=-\tfrac{1}{8}\sqrt{3}. \quad (3)$$

This cubic is OF THE FORM

$$x^3+px=q, \quad (4)$$

where

$$p=-\tfrac{3}{4} \quad (5)$$

$$q=-\tfrac{1}{8}\sqrt{3}. \quad (6)$$

The DISCRIMINANT is then

$$D \equiv \left(\frac{p}{3}\right)^3 + \left(\frac{q}{2}\right)^2$$

$$= \left(-\frac{1}{4}\right)^3 + \left(\frac{\sqrt{3}}{16}\right)^2 = -\frac{1}{16 \cdot 4} + \frac{3}{16 \cdot 16} = \frac{-4+3}{256}$$

$$= -\frac{1}{256} < 0. \quad (7)$$

There are therefore three REAL distinct roots, which are approximately −0.9848, 0.3240, and 0.6428. We want the one in the first QUADRANT, which is 0.3240.

$$\sin\left(\frac{\pi}{9}\right) = \sqrt{-\frac{\sqrt{3}}{16} + \sqrt{-\frac{1}{256}}} + \sqrt{-\frac{\sqrt{3}}{16} - \sqrt{-\frac{1}{256}}}$$

$$= \sqrt{-\frac{\sqrt{3}}{16} + \frac{1}{16}\,i} - \sqrt{\frac{\sqrt{3}}{16} + \frac{1}{16}\,i}$$

$$= 2^{-4/3}\left(\sqrt{i - \sqrt{3}} - \sqrt{i + \sqrt{3}}\right)$$

$$\approx 0.34202 \quad (8)$$

Similarly,

$$\cos\left(\frac{\pi}{9}\right) = 2^{-4/3}\left(\sqrt{1 + i\sqrt{3}} + \sqrt{1 - i\sqrt{3}}\right)$$

$$\approx 0.93969. \quad (9)$$

Because of the NEWTON'S RELATIONS, we have the identities

$$\sin\left(\frac{\pi}{9}\right)\sin\left(\frac{2\pi}{9}\right)\sin\left(\frac{4\pi}{9}\right) = \tfrac{1}{8}\sqrt{3} \quad (10)$$

$$\cos\left(\frac{\pi}{9}\right)\cos\left(\frac{2\pi}{9}\right)\cos\left(\frac{4\pi}{9}\right) = \tfrac{1}{8} \quad (11)$$

$$\tan\left(\frac{\pi}{9}\right)\tan\left(\frac{2\pi}{9}\right)\tan\left(\frac{4\pi}{9}\right) = \sqrt{3}. \quad (12)$$

(11) is known as MORRIE'S LAW.

See also MORRIE'S LAW, NONAGON, STAR OF GOLIATH

Trigonometry Values Pi/10

$$\cos\left(\frac{\pi}{10}\right) = \tfrac{1}{4}\sqrt{10 + 2\sqrt{5}} \quad (1)$$

$$\cos\left(\frac{3\pi}{10}\right) = \tfrac{1}{4}\sqrt{10 - 2\sqrt{5}} \quad (2)$$

$$\cos\left(\frac{\pi}{10}\right) = \sqrt{5 + 2\sqrt{5}} \quad (3)$$

$$\cot\left(\frac{3\pi}{10}\right) = \sqrt{5 - 2\sqrt{5}} \quad (4)$$

$$\csc\left(\frac{\pi}{10}\right) = 1 + \sqrt{5} \quad (5)$$

$$\csc\left(\frac{3\pi}{10}\right) = \sqrt{5} - 1 \quad (6)$$

$$\sec\left(\frac{\pi}{10}\right) = \tfrac{1}{5}\sqrt{50 - 10\sqrt{5}} \quad (7)$$

$$\sec\left(\frac{3\pi}{10}\right) = \tfrac{1}{5}\sqrt{50 - 10\sqrt{5}} \quad (8)$$

$$\sin\left(\frac{\pi}{10}\right) = \tfrac{1}{4}\left(\sqrt{5} - 1\right) \quad (9)$$

$$\sin\left(\frac{3\pi}{10}\right) = \tfrac{1}{4}\left(1 + \sqrt{5}\right) \quad (10)$$

$$\tan\left(\frac{\pi}{10}\right) = \tfrac{1}{5}\sqrt{25 - 10\sqrt{5}} \quad (11)$$

$$\tan\left(\frac{3\pi}{10}\right) = \tfrac{1}{5}\sqrt{25 + 10\sqrt{5}} \quad (12)$$

To derive these formulas, start with

$$\sin\left(\frac{\pi}{10}\right) = \sin\left(\frac{1}{2}\cdot\frac{\pi}{5}\right) = \sqrt{\tfrac{1}{2}\left[1 - \cos\left(\frac{\pi}{5}\right)\right]}$$

$$= \sqrt{\tfrac{1}{2}\left[1 - \tfrac{1}{4}(1 + \sqrt{5})\right]} = \tfrac{1}{4}\left(\sqrt{5} - 1\right). \quad (13)$$

So we have

$$\cos\left(\frac{\pi}{10}\right) = \cos\left(\frac{1}{2}\cdot\frac{\pi}{5}\right) = \sqrt{\frac{1}{2}\left[1 + \cos\left(\frac{\pi}{5}\right)\right]}$$

$$= \sqrt{\tfrac{1}{2}\left[1 + \tfrac{1}{4}(1 + \sqrt{5})\right]}$$

$$= \tfrac{1}{4}\sqrt{10 + 2\sqrt{5}} \quad (14)$$

and

$$\tan\left(\frac{\pi}{10}\right) = \sqrt{\frac{3 - \sqrt{5}}{5 + \sqrt{5}}} = \tfrac{1}{5}\sqrt{25 - 10\sqrt{5}}. \quad (15)$$

An interesting near-identity is given by

$$\frac{1}{4}\left[\cos\left(\tfrac{1}{10}\right)+\cosh\left(\tfrac{1}{10}\right)+2\cos\left(\tfrac{1}{20}\sqrt{2}\right)\cosh\left(\tfrac{1}{20}\sqrt{2}\right)\right]\approx 1. \quad (16)$$

In fact, the left-hand side is approximately equal to $1+2.480\times 10^{-13}$.

See also Decagon, Decagram

Trigonometry Values Pi/11

Trigonometric functions of $n\pi/11$ for n an integer cannot be expressed in terms of sums, products, and finite root extractions on *real* rational numbers because 11 is not a Fermat prime. This also means that the undecagon is not a constructible polygon.

However, exact expressions involving roots of *complex* numbers can still be derived using the multiple-angle formula

$$\sin(n\alpha)=(-1)^{(n-1)/2}T_n(\sin\alpha), \quad (1)$$

where T_n is a Chebyshev polynomial of the first kind. Plugging in $n=11$ gives

$$\sin(11\alpha)=\sin\alpha(11-220\sin^2\alpha+1232\sin^4\alpha$$
$$-2816\sin^6\alpha+2816\sin^8-1024\sin^{10}\alpha). \quad (2)$$

Letting $\alpha\equiv\pi/11$ and $x\equiv\sin^2\alpha$ then gives

$$\sin\pi=0=11-220x+1232x^2-2816x^3$$
$$+2816x^4-1024x^5. \quad (3)$$

This equation is an irreducible quintic equation, so an analytic solution involving finite root extractions does not exist. The numerical roots are $x=$ 0.07937, 0.29229, 0.57115, 0.82743, 0.97974. So $\sin\alpha=0.2817$, $\sin(2\alpha)=0.5406$, $\sin(3\alpha)=0.7557$, $\sin(4\alpha)=0.9096$, $\sin(5\alpha)=0.9898$. From one of Newton's identities,

$$\sin\left(\frac{\pi}{11}\right)\sin\left(\frac{2\pi}{11}\right)\sin\left(\frac{3\pi}{11}\right)\sin\left(\frac{4\pi}{11}\right)\sin\left(\frac{5\pi}{11}\right)=\sqrt{\frac{11}{1024}}$$
$$=\frac{\sqrt{11}}{32} \quad (4)$$

$$\cos\left(\frac{\pi}{11}\right)\cos\left(\frac{2\pi}{11}\right)\cos\left(\frac{3\pi}{11}\right)\cos\left(\frac{4\pi}{11}\right)\cos\left(\frac{5\pi}{11}\right)=\frac{1}{32} \quad (5)$$

$$\tan\left(\frac{\pi}{11}\right)\tan\left(\frac{2\pi}{11}\right)\tan\left(\frac{3\pi}{11}\right)\tan\left(\frac{4\pi}{11}\right)\tan\left(\frac{5\pi}{11}\right)$$
$$=\sqrt{11}. \quad (6)$$

The trigonometric functions of $\pi/11$ also obey the identity

$$\tan\left(\frac{3\pi}{11}\right)+4\sin\left(\frac{2\pi}{11}\right)=\sqrt{11}. \quad (7)$$

Trigonometry Values Pi/12

$$\cos\left(\frac{\pi}{12}\right)=\tfrac{1}{4}\left(\sqrt{6}+\sqrt{2}\right) \quad (1)$$

$$\cos\left(\frac{5\pi}{12}\right)=\tfrac{1}{4}\left(\sqrt{6}-\sqrt{2}\right) \quad (2)$$

$$\cot\left(\frac{\pi}{12}\right)=2+\sqrt{3} \quad (3)$$

$$\cot\left(\frac{5\pi}{12}\right)=2-\sqrt{3} \quad (4)$$

$$\cot\left(\frac{\pi}{12}\right)=\sqrt{6}+\sqrt{2} \quad (5)$$

$$\csc\left(\frac{5\pi}{12}\right)=\sqrt{6}-\sqrt{2} \quad (6)$$

$$\sec\left(\frac{\pi}{12}\right)=\sqrt{6}-\sqrt{2} \quad (7)$$

$$\sec\left(\frac{5\pi}{12}\right)=\sqrt{6}+\sqrt{2} \quad (8)$$

$$\sin\left(\frac{\pi}{12}\right)=\tfrac{1}{4}\left(\sqrt{6}-\sqrt{2}\right) \quad (9)$$

$$\sin\left(\frac{5\pi}{12}\right)=\tfrac{1}{4}\left(\sqrt{6}+\sqrt{2}\right) \quad (10)$$

$$\tan\left(\frac{\pi}{12}\right)=2-\sqrt{3} \quad (11)$$

$$\tan\left(\frac{5\pi}{12}\right)=2+\sqrt{3}. \quad (12)$$

These can be derived using

$$\sin\left(\frac{\pi}{12}\right) = \sin\left(\frac{\pi}{3} - \frac{\pi}{4}\right)$$
$$= -\sin\left(\frac{\pi}{4}\right)\cos\left(\frac{\pi}{3}\right) + \sin\left(\frac{\pi}{3}\right)\cos\left(\frac{\pi}{4}\right)$$
$$= -\tfrac{1}{2}\sqrt{2}\left(\tfrac{1}{2}\right) + \tfrac{1}{2}\sqrt{3}\left(\tfrac{1}{2}\sqrt{2}\right)$$
$$= \tfrac{1}{4}\left(\sqrt{6} - \sqrt{2}\right). \qquad (13)$$

Similarly,

$$\cos\left(\frac{\pi}{12}\right) = \cos\left(\frac{\pi}{3} - \frac{\pi}{4}\right)$$
$$= \cos\left(\frac{\pi}{4}\right)\cos\left(\frac{\pi}{3}\right) - \sin\left(\frac{\pi}{3}\right)\sin\left(\frac{\pi}{4}\right)$$
$$= \tfrac{1}{2}\left(\tfrac{1}{2}\sqrt{2}\right) + \tfrac{1}{2}\sqrt{3}\left(-\tfrac{1}{2}\sqrt{2}\right)$$
$$= \tfrac{1}{4}\left(\sqrt{6} - \sqrt{2}\right). \qquad (14)$$

Trigonometry Values Pi/15

$$\cos\left(\frac{\pi}{15}\right) = \tfrac{1}{8}\left(\sqrt{30+6\sqrt{5}} + \sqrt{5} - 1\right) \qquad (1)$$
$$\cos\left(\frac{2\pi}{15}\right) = \tfrac{1}{8}\left(\sqrt{30-6\sqrt{5}} + \sqrt{5} + 1\right) \qquad (2)$$
$$\cos\left(\frac{4\pi}{15}\right) = \tfrac{1}{8}\left(\sqrt{30+6\sqrt{5}} - \sqrt{5} + 1\right) \qquad (3)$$
$$\cos\left(\frac{7\pi}{15}\right) = \tfrac{1}{8}\left(\sqrt{30-6\sqrt{5}} - \sqrt{5} - 1\right) \qquad (4)$$
$$\cot\left(\frac{\pi}{15}\right) = \sqrt{7+2\sqrt{5}+2\sqrt{15+6\sqrt{5}}} \qquad (5)$$
$$\cot\left(\frac{2\pi}{15}\right) = \sqrt{7-2\sqrt{5}+2\sqrt{15-6\sqrt{5}}} \qquad (6)$$
$$\cot\left(\frac{4\pi}{15}\right) = \sqrt{7+2\sqrt{5}-2\sqrt{15+6\sqrt{5}}} \qquad (7)$$
$$\cot\left(\frac{7\pi}{15}\right) = \sqrt{7-2\sqrt{5}-2\sqrt{15-6\sqrt{5}}} \qquad (8)$$
$$\csc\left(\frac{\pi}{15}\right) = \sqrt{8+2\sqrt{5}+2\sqrt{15+6\sqrt{5}}} \qquad (9)$$
$$\csc\left(\frac{2\pi}{15}\right) = \sqrt{8-2\sqrt{5}+2\sqrt{15-6\sqrt{5}}} \qquad (10)$$
$$\csc\left(\frac{4\pi}{15}\right) = \sqrt{8+2\sqrt{5}-2\sqrt{15+6\sqrt{5}}} \qquad (11)$$
$$\csc\left(\frac{7\pi}{15}\right) = \sqrt{8-2\sqrt{5}-2\sqrt{15-6\sqrt{5}}} \qquad (12)$$
$$\sec\left(\frac{\pi}{15}\right) = +2-\sqrt{5}+\sqrt{15-6\sqrt{5}} \qquad (13)$$
$$\sec\left(\frac{2\pi}{15}\right) = -2-\sqrt{5}+\sqrt{15+6\sqrt{5}} \qquad (14)$$
$$\sec\left(\frac{4\pi}{15}\right) = -2+\sqrt{5}+\sqrt{15-6\sqrt{5}} \qquad (15)$$
$$\sec\left(\frac{7\pi}{15}\right) = +2+\sqrt{5}+\sqrt{15+6\sqrt{5}} \qquad (16)$$
$$\sin\left(\frac{\pi}{15}\right) = \tfrac{1}{4}\sqrt{7-\sqrt{5}-\sqrt{30-6\sqrt{5}}} \qquad (17)$$
$$\sin\left(\frac{2\pi}{15}\right) = \tfrac{1}{4}\sqrt{7+\sqrt{5}-\sqrt{30+6\sqrt{5}}} \qquad (18)$$
$$\sin\left(\frac{4\pi}{15}\right) = \tfrac{1}{4}\sqrt{7-\sqrt{5}+\sqrt{30-6\sqrt{5}}} \qquad (19)$$
$$\sin\left(\frac{7\pi}{15}\right) = \tfrac{1}{4}\sqrt{7+\sqrt{5}+\sqrt{30+6\sqrt{5}}} \qquad (20)$$
$$\tan\left(\frac{\pi}{15}\right) = \sqrt{23-10\sqrt{5}-2\sqrt{255+114\sqrt{5}}} \qquad (21)$$
$$\tan\left(\frac{2\pi}{15}\right) = \sqrt{23+10\sqrt{5}-2\sqrt{255+114\sqrt{5}}} \qquad (22)$$
$$\tan\left(\frac{4\pi}{15}\right) = \sqrt{23-10\sqrt{5}+2\sqrt{255+114\sqrt{5}}} \qquad (23)$$
$$\tan\left(\frac{7\pi}{15}\right) = \sqrt{23+10\sqrt{5}+2\sqrt{255+114\sqrt{5}}}. \qquad (24)$$

These can be derived using the TRIGONOMETRIC ADDITION FORMULAS

$$\sin\left(\frac{\pi}{15}\right) = \sin\left(\frac{\pi}{6} - \frac{\pi}{10}\right)$$

$$= \sin\left(\frac{\pi}{6}\right)\cos\left(\frac{\pi}{10}\right) - \sin\left(\frac{\pi}{10}\right)\cos\left(\frac{\pi}{6}\right)$$

$$= \frac{1}{2}\sqrt{\frac{1}{8}\left(5+\sqrt{5}\right)} - \frac{\sqrt{3}}{2}\frac{1}{4}\left(\sqrt{5}-1\right)$$

$$= \tfrac{1}{16}\left(2\sqrt{3} - 2\sqrt{15} + \sqrt{40+8\sqrt{5}}\right) \qquad (25)$$

and

$$\cos\left(\frac{\pi}{15}\right) = \cos\left(\frac{\pi}{6} - \frac{\pi}{10}\right)$$

$$= \cos\left(\frac{\pi}{6}\right)\cos\left(\frac{\pi}{10}\right) + \sin\left(\frac{\pi}{6}\right)\sin\left(\frac{\pi}{10}\right)$$

$$= \frac{\sqrt{3}}{2}\sqrt{\frac{1}{8}\left(5+\sqrt{5}\right)} + \frac{1}{2}\frac{1}{4}\left(\sqrt{5}-1\right)$$

$$= \tfrac{1}{8}\left(\sqrt{30+6\sqrt{5}} + \sqrt{5} - 1\right). \qquad (26)$$

$$\cot\left(\frac{3\pi}{16}\right) = -1+\sqrt{2}+\sqrt{4-2\sqrt{2}} \qquad (6)$$

$$\cot\left(\frac{5\pi}{16}\right) = +1-\sqrt{2}+\sqrt{4-2\sqrt{2}} \qquad (7)$$

$$\cot\left(\frac{7\pi}{16}\right) = -1-\sqrt{2}+\sqrt{4+2\sqrt{2}} \qquad (8)$$

$$\csc\left(\frac{\pi}{16}\right) = \sqrt{8+4\sqrt{2}+2\sqrt{20+14\sqrt{2}}} \qquad (9)$$

$$\csc\left(\frac{3\pi}{16}\right) = \sqrt{8-4\sqrt{2}+2\sqrt{20-14\sqrt{2}}} \qquad (10)$$

$$\csc\left(\frac{5\pi}{16}\right) = \sqrt{8-4\sqrt{2}-2\sqrt{20-14\sqrt{2}}} \qquad (11)$$

$$\csc\left(\frac{7\pi}{16}\right) = \sqrt{8+4\sqrt{2}-2\sqrt{20+14\sqrt{2}}} \qquad (12)$$

$$\sec\left(\frac{\pi}{16}\right) = \sqrt{8+4\sqrt{2}-2\sqrt{20+14\sqrt{2}}} \qquad (13)$$

$$\sec\left(\frac{3\pi}{16}\right) = \sqrt{8-4\sqrt{2}-2\sqrt{20-14\sqrt{2}}} \qquad (14)$$

$$\sec\left(\frac{5\pi}{16}\right) = \sqrt{8-4\sqrt{2}+2\sqrt{20-14\sqrt{2}}} \qquad (15)$$

$$\sec\left(\frac{7\pi}{16}\right) = \sqrt{8+4\sqrt{2}+2\sqrt{20+14\sqrt{2}}} \qquad (16)$$

$$\sin\left(\frac{\pi}{16}\right) = \tfrac{1}{2}\sqrt{2-\sqrt{2+\sqrt{2}}} \qquad (17)$$

$$\sin\left(\frac{3\pi}{16}\right) = \tfrac{1}{2}\sqrt{2-\sqrt{2-\sqrt{2}}} \qquad (18)$$

$$\sin\left(\frac{5\pi}{16}\right) = \tfrac{1}{2}\sqrt{2+\sqrt{2-\sqrt{2}}} \qquad (19)$$

$$\sin\left(\frac{7\pi}{16}\right) = \tfrac{1}{2}\sqrt{2+\sqrt{2+\sqrt{2}}} \qquad (20)$$

$$\tan\left(\frac{\pi}{16}\right) = \sqrt{4+2\sqrt{2}}-\sqrt{2}-1 \qquad (21)$$

$$\tan\left(\frac{3\pi}{16}\right) = \sqrt{4-2\sqrt{2}}-\sqrt{2}+1 \qquad (22)$$

$$\tan\left(\frac{5\pi}{16}\right) = \sqrt{4-2\sqrt{2}}+\sqrt{2}-1 \qquad (23)$$

$$\tan\left(\frac{7\pi}{16}\right) = \sqrt{4+2\sqrt{2}}+\sqrt{2}+1. \qquad (24)$$

These can be derived from the HALF-ANGLE FORMULAS

$$\sin\left(\frac{\pi}{16}\right) = \sin\left(\frac{1}{2}\cdot\frac{\pi}{8}\right)$$

$$= \sqrt{\tfrac{1}{2}\left(1-\cos\frac{\pi}{8}\right)} = \sqrt{\tfrac{1}{2}\left(1-\tfrac{1}{2}\sqrt{2+\sqrt{2}}\right)}$$

$$= \sqrt{\tfrac{1}{2} - \tfrac{1}{4}\sqrt{2+\sqrt{2}}} = \tfrac{1}{2}\sqrt{2-\sqrt{2+\sqrt{2}}} \quad (25)$$

$$\cos\left(\frac{\pi}{16}\right) = \cos\left(\frac{1}{2}\cdot\frac{\pi}{8}\right)$$

$$= \sqrt{\frac{1}{2}\left(1+\cos\frac{\pi}{8}\right)} = \sqrt{\tfrac{1}{2}\left(1+\tfrac{1}{2}\sqrt{2+\sqrt{2}}\right)}$$

$$= \sqrt{\tfrac{1}{2} + \tfrac{1}{4}\sqrt{2+\sqrt{2}}} = \tfrac{1}{2}\sqrt{2+\sqrt{2+\sqrt{2}}} \quad (26)$$

$$\tan\left(\frac{\pi}{16}\right) = \sqrt{\frac{2-\sqrt{2+\sqrt{2}}}{2+\sqrt{2+\sqrt{2}}}}$$

$$= \sqrt{4+2\sqrt{2}} - \sqrt{2} - 1. \quad (27)$$

See also HEXADECAGON

Trigonometry Values Pi/17

Rather surprisingly, trigonometric functions of $n\pi/17$ for n an integer can be expressed in terms of sums, products, and finite ROOT EXTRACTIONS because 17 is a FERMAT PRIME. This makes the HEPTADECAGON a CONSTRUCTIBLE, as first proved by Gauss. Although Gauss did not actually explicitly provide a construction, he did derive the trigonometric formulas below using a series of intermediate variables from which the final expressions were then built up.

Let

$$\epsilon \equiv \sqrt{17+\sqrt{17}} \quad (1)$$

$$\epsilon^* \equiv \sqrt{17-\sqrt{17}} \quad (2)$$

$$\delta \equiv \sqrt{17} - 1 \quad (3)$$

$$\alpha \equiv \sqrt{34+6\sqrt{17}+\sqrt{2}\left(\sqrt{17}-1\right)\epsilon^* - 8\sqrt{2}\epsilon} \quad (4)$$

$$\beta \equiv 2\sqrt{17+3\sqrt{17}-2\sqrt{2}\epsilon - \sqrt{2}\epsilon^*}, \quad (5)$$

then

$$\sin\left(\frac{\pi}{17}\right) = \tfrac{1}{8}\sqrt{2}\sqrt{\epsilon^{*2} - \sqrt{2(\alpha+\epsilon^*)}}$$

$$\approx 0.18375 \quad (6)$$

$$\cos\left(\frac{\pi}{17}\right) = \tfrac{1}{8}\sqrt{2}\sqrt{15+\sqrt{17}+\sqrt{2(\alpha+\epsilon^*)}}$$

$$\approx 0.98297 \quad (7)$$

$$\sin\left(\frac{2\pi}{17}\right) = \tfrac{1}{16}\sqrt{2}\sqrt{4\epsilon^{*2} - 2\sqrt{2}\delta\epsilon^* + 8\sqrt{2}\epsilon - \left(\sqrt{2}\delta + 2\epsilon^*\right)\alpha}$$

$$\approx 0.36124 \quad (8)$$

$$\cos\left(\frac{2\pi}{17}\right) = \tfrac{1}{16}\left[\delta + \sqrt{2(\alpha+\epsilon^*)}\right]$$

$$\approx 0.93247 \quad (9)$$

$$\sin\left(\frac{4\pi}{17}\right) = \tfrac{1}{128}\left[\sqrt{2}\delta + 2(\alpha+\epsilon^*)\right]$$

$$\times\left[4\epsilon^{*2} - 2\sqrt{2}\delta\epsilon^* + 8\sqrt{2}\epsilon - \left(\sqrt{2}\delta + 2\epsilon^*\right)\alpha\right]^{1/2}$$

$$\approx 0.67370 \quad (10)$$

$$\sin\left(\frac{8\pi}{17}\right) = \tfrac{1}{16}[136 - 8\sqrt{17} + 8\sqrt{2}\epsilon - 2(\sqrt{34} - 3\sqrt{2})\epsilon^*$$

$$+2\beta(\delta + \sqrt{2}\epsilon^*)]^{1/2} \approx 0.99573 \quad (11)$$

$$\cos\left(\frac{8\pi}{17}\right) = \frac{1}{16}\left(\delta + \sqrt{2}\epsilon^* - 2\sqrt{17+3\sqrt{17} - \sqrt{2}\epsilon^* - 2\sqrt{2}\epsilon}\right)$$

$$\approx 0.09227. \quad (12)$$

There are some interesting analytic formulas involving the trigonometric functions of $n\pi/17$. Define

$$P(x) \equiv (x-1)(x-2)\left(x^2+1\right) \quad (13)$$

$$g_1(x) \equiv \frac{2+\sqrt{P(x)}}{1-x} \quad (14)$$

$$g_4(x) \equiv \frac{2-\sqrt{P(x)}}{1-x} \quad (15)$$

$$f_i(x) \equiv \tfrac{1}{4}[g_i(x) - 1] \quad (16)$$

$$a \equiv \tfrac{1}{4}\tan^{-1} 4, \quad (17)$$

where $i = 1$ or 4. Then

$$f_1(\tan a) = \cos\left(\frac{2\pi}{17}\right) \quad (18)$$

$$f_4(\tan a) = \cos\left(\frac{8\pi}{17}\right). \quad (19)$$

Another interesting identity is given by

$$\tan\left(\tfrac{1}{4}\tan^{-1} 4\right) = 2\left[\cos\left(\frac{6\pi}{17}\right) + \cos\left(\frac{10\pi}{17}\right)\right], \quad (20)$$

where both sides are equal to

$$C = \frac{\sqrt{2(17+\sqrt{17})} - \sqrt{17} - 1}{4} \quad (21)$$

(Wickner 1999).

Trigonometry Values Pi/18

The exact values of $\cos(\pi/18)$ and $\sin(\pi/18)$ can be given by infinite NESTED RADICALS

$$\sin\left(\frac{\pi}{18}\right) = \tfrac{1}{2}\sqrt{2-\sqrt{2+\sqrt{2+\sqrt{2-\ldots}}}},$$

where the sequence of signs $+$, $+$, $-$ repeats with period 3, and

$$\cos\left(\frac{\pi}{18}\right) = \tfrac{1}{16}\sqrt{3}\left(\sqrt{8-\sqrt{8-\sqrt{8+\sqrt{8-\ldots}}}}+1\right),$$

where the sequence of signs $-$, $-$, $+$ repeats with period 3.

Trigonometry Values Pi/20

$$\cos\left(\frac{\pi}{20}\right) = \tfrac{1}{4}\sqrt{8+2\sqrt{10+2\sqrt{5}}} \tag{1}$$

$$\cos\left(\frac{3\pi}{20}\right) = \tfrac{1}{4}\sqrt{8+2\sqrt{10+2\sqrt{5}}} \tag{2}$$

$$\cos\left(\frac{7\pi}{20}\right) = \tfrac{1}{4}\sqrt{8-2\sqrt{10-2\sqrt{5}}} \tag{3}$$

$$\cos\left(\frac{9\pi}{20}\right) = \tfrac{1}{4}\sqrt{8-2\sqrt{10-2\sqrt{5}}} \tag{4}$$

$$\cot\left(\frac{\pi}{20}\right) = +1+\sqrt{5}+\sqrt{5+2\sqrt{5}} \tag{5}$$

$$\cot\left(\frac{3\pi}{20}\right) = -1+\sqrt{5}+\sqrt{5-2\sqrt{5}} \tag{6}$$

$$\cot\left(\frac{7\pi}{20}\right) = -1+\sqrt{5}-\sqrt{5-2\sqrt{5}} \tag{7}$$

$$\cot\left(\frac{9\pi}{20}\right) = +1+\sqrt{5}-\sqrt{5+2\sqrt{5}} \tag{8}$$

$$\csc\left(\frac{\pi}{20}\right) = \sqrt{12+4\sqrt{5}+2\sqrt{50+22\sqrt{5}}} \tag{9}$$

$$\csc\left(\frac{3\pi}{20}\right) = \sqrt{12-4\sqrt{5}+2\sqrt{50-22\sqrt{5}}} \tag{10}$$

$$\csc\left(\frac{5\pi}{20}\right) = \sqrt{12-4\sqrt{5}-2\sqrt{50-22\sqrt{5}}} \tag{11}$$

$$\csc\left(\frac{7\pi}{20}\right) = \sqrt{12+4\sqrt{5}-2\sqrt{50+22\sqrt{5}}} \tag{12}$$

$$\sec\left(\frac{\pi}{20}\right) = \sqrt{12+4\sqrt{5}-2\sqrt{50+22\sqrt{5}}} \tag{13}$$

$$\sec\left(\frac{3\pi}{20}\right) = \sqrt{12-4\sqrt{5}-2\sqrt{50-22\sqrt{5}}} \tag{14}$$

$$\sec\left(\frac{5\pi}{20}\right) = \sqrt{12-4\sqrt{5}+2\sqrt{50-22\sqrt{5}}} \tag{15}$$

$$\sec\left(\frac{7\pi}{20}\right) = \sqrt{12+4\sqrt{5}+2\sqrt{50+22\sqrt{5}}} \tag{16}$$

$$\sin\left(\frac{\pi}{20}\right) = \tfrac{1}{4}\sqrt{8-20\sqrt{10+2\sqrt{5}}} \tag{17}$$

$$\sin\left(\frac{3\pi}{20}\right) = \tfrac{1}{4}\sqrt{8-20\sqrt{10-2\sqrt{5}}} \tag{18}$$

$$\sin\left(\frac{7\pi}{20}\right) = \tfrac{1}{4}\sqrt{8+20\sqrt{10-2\sqrt{5}}} \tag{19}$$

$$\sin\left(\frac{9\pi}{20}\right) = \tfrac{1}{4}\sqrt{8+20\sqrt{10+2\sqrt{5}}} \tag{20}$$

$$\tan\left(\frac{\pi}{20}\right) = +1+\sqrt{5}-\sqrt{5+2\sqrt{5}} \tag{21}$$

$$\tan\left(\frac{3\pi}{20}\right) = -1+\sqrt{5}-\sqrt{5-2\sqrt{5}} \tag{22}$$

$$\tan\left(\frac{7\pi}{20}\right) = -1+\sqrt{5}+\sqrt{5-2\sqrt{5}} \tag{23}$$

$$\tan\left(\frac{9\pi}{20}\right) = +1+\sqrt{5}+\sqrt{5+2\sqrt{5}}. \tag{24}$$

These can be derived from the HALF-ANGLE FORMULAS

$$\sin\left(\frac{\pi}{20}\right)=\sin\left(\frac{1}{2}\frac{\pi}{10}\right)=\sqrt{\frac{1}{2}\left(1-\cos\frac{\pi}{10}\right)}$$

$$=\tfrac{1}{4}\sqrt{8-2\sqrt{10+2\sqrt{5}}}$$

$$\cos\left(\frac{\pi}{20}\right)=\cos\left(\frac{1}{2}\frac{\pi}{10}\right)=\sqrt{\frac{1}{2}\left(1+\cos\frac{\pi}{10}\right)}$$

$$=\tfrac{1}{4}\sqrt{8+2\sqrt{10+2\sqrt{5}}}$$

$$\tan\left(\frac{\pi}{20}\right)=1+\sqrt{5}-\sqrt{5+2\sqrt{5}}.$$

An interesting near-identity is given by

$$\frac{1}{4}\left[\cos\left(\tfrac{1}{10}\right)+\cosh\left(\tfrac{1}{10}\right)+2\cos\left(\tfrac{1}{20}\sqrt{2}\right)\cosh\left(\tfrac{1}{20}\sqrt{2}\right)\right]\approx 1. \quad (25)$$

In fact, the left-hand side is approximately equal to $1+2.480\times 10^{-13}$.

Trigonometry Values Pi/24

Trihedral Angle

TRIHEDRON

Trihedron

A TRIPLE of three arbitrary vectors with common vertex (Altshiller-Court 1979), often called a trihedral angle since it determines three planes.

The vectors are often taken to be unit vectors, and the term trihedron is frequently encountered in the consideration of the unit ORTHOGONAL VECTORS given by **T**, **N**, and **B** (TANGENT VECTOR, NORMAL VECTOR, and BINORMAL VECTOR).

See also BINORMAL VECTOR, CENTROIDAL LINE, DIHEDRAL ANGLE, ISOCLINAL LINE, ISOCLINAL PLANE, NORMAL VECTOR, ORTHOCENTRIC LINE, TANGENT VECTOR

Trilinear Coordinates

Given a TRIANGLE ΔABC, the trilinear coordinates of a point P with respect to ΔABC are an ordered TRIPLE of numbers, each of which is PROPORTIONAL to the directed distance from P to one of the side lines. Trilinear coordinates are denoted $\alpha : \beta : \gamma$ or $(\alpha,\ \beta,\ \gamma)$ and also are known as homogeneous coordinates or "trilinears." Trilinear coordinates were introduced by Plücker in 1835. Since it is only the ratio of distances that is significant, the triplet of trilinear coordinates obtained by multiplying a given triplet by any nonzero constant describes the same point, so

$$\alpha : \beta : \gamma = \mu\alpha : \mu\beta : \mu\gamma. \tag{1}$$

For simplicity, the three VERTICES A, B, and C of a triangle are commonly written as $1:0:0$, $0:1:0$, and $0:0:1$, respectively.

Trilinear coordinates can be normalized so that they give the *actual* directed distances from P to each of the sides. To perform the normalization, let the point P in the above diagram have trilinear coordinates $\alpha : \beta : \gamma$ and lie at distances a', b', and c' from the sides BC, AC, and AB, respectively. Then the distances $a' = k\alpha$, $b' = k\beta$, and $c' = k\gamma$ can be found by writing Δ_a for the AREA of ΔBPC, and similarly for Δ_b and Δ_c. We then have

$$\Delta = \Delta_a + \Delta_b + \Delta_c = \tfrac{1}{2}aa' + \tfrac{1}{2}bb' + \tfrac{1}{2}cc'$$

$$= \tfrac{1}{2}(ak\alpha + bk\beta + ck\gamma) = \tfrac{1}{2}k(a\alpha + b\beta + c\gamma). \tag{2}$$

so

$$k \equiv \frac{2\Delta}{a\alpha + b\beta + c\gamma}, \tag{3}$$

where Δ is the AREA of ΔABC and a, b, and c are the lengths of its sides (Kimberling 1998, pp. 26–27). To obtain trilinear coordinates giving the actual distances, take $k = 1$, so we have the coordinates

$$a' : b' : c'. \tag{4}$$

These normalized trilinear coordinates are known as EXACT TRILINEAR COORDINATES.

The trilinear coordinates of the line

$$ux + vy + wz = 0 \tag{5}$$

are

$$u : v : w = ab_A : bd_B : cd_C, \tag{6}$$

where d_i is the POINT-LINE DISTANCE from VERTEX i to the LINE.

The homogeneous BARYCENTRIC COORDINATES corresponding to trilinear coordinates $\alpha : \beta : \gamma$ are $(a\alpha,\ b\beta,\ c\gamma)$, and the trilinear coordinates corresponding to homogeneous BARYCENTRIC COORDINATES $(t_1,\ t_2,\ t_3)$ are $t_1/a : t_2/b : t_3/c$.

Important points $\alpha : \beta : \gamma$ of a triangle are called TRIANGLE CENTERS, and the vector functions describing the location of the points in terms of side length, angles, or both, are called TRIANGLE CENTER FUNCTIONS $\mathbf{f}(a,\ b,\ c)$. Since by symmetry, triangle center functions are of the form

$$\mathbf{f}(a,\ b,\ c) = f(a,\ b,\ c) : f(b,\ c,\ a) : f(c,\ a,\ b), \tag{7}$$

it is common to call the scalar function $f(a,\ b,\ c)$ "the" triangle center function. Note also that side lengths and angles are interconvertible through the LAW OF COSINES, so a triangle center function may be given in terms of side lengths, angles, or both. Trilinear coordinates for some common triangle centers are summarized in the following table, where A, B, and C are the angles at the corresponding vertices and a, b, and c are the opposite side lengths. Here, the normalizations have been chosen to give the simplest possible form.

Point	Trilinear Center Function
CENTROID M	$\csc A$, $1/a$
CIRCUMCENTER O	$\cos A$
DE LONGCHAMPS POINT	$\cos A - \cos B \cos C$
EQUAL DETOUR POINT	$\sec\left(\frac{1}{2}A\right)\cos\left(\frac{1}{2}B\right)\cos\left(\frac{1}{2}C\right) + 1$
FEUERBACH POINT F	$1 - \cos(B - C)$
INCENTER I	1
ISOPERIMETRIC POINT	$\sec\left(\frac{1}{2}A\right)\cos\left(\frac{1}{2}B\right)\cos\left(\frac{1}{2}C\right) - 1$
SYMMEDIAN POINT	a
NINE-POINT CENTER N	$\cos(B - C)$
ORTHOCENTER H	$\cos B \cos C$
vertex A	$1:0:0$
vertex B	$0:1:0$
vertex C	$0:0:1$

To convert trilinear coordinates to a vector position for a given triangle specified by the x- and y-coordinates of its axes, pick two UNIT VECTORS along the sides. For instance, pick

$$\hat{\mathbf{a}} = \begin{bmatrix} a_1 \\ a_2 \end{bmatrix} \quad (8)$$

$$\hat{\mathbf{c}} = \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \quad (9)$$

where these are the UNIT VECTORS BC and AB. Assume the TRIANGLE has been labeled such that $A = \mathbf{x}_1$ is the lower rightmost VERTEX and $C = \mathbf{x}_2$. Then the VECTORS obtained by traveling l_a and l_c along the sides and then inward PERPENDICULAR to them must meet

$$\begin{bmatrix} x_1 \\ y_1 \end{bmatrix} + l_c \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} - k\gamma \begin{bmatrix} c_2 \\ -c_1 \end{bmatrix} = \begin{bmatrix} x_2 \\ y_2 \end{bmatrix} + l_a \begin{bmatrix} a_1 \\ a_2 \end{bmatrix} - k\alpha \begin{bmatrix} a_2 \\ -a_1 \end{bmatrix}. \quad (10)$$

Solving the two equations

$$x_1 + l_c c_1 - k\gamma c_2 = x_2 + l_a a_1 - k\alpha a_2 \quad (11)$$

$$y_1 + l_c c_2 + k\gamma c_1 = y_2 + l_a a_2 + k\alpha a_1, \quad (12)$$

gives

$$l_a = \frac{k\alpha(a_1c_1 + a_2c_2) - \gamma k(c_1^2 + c_2^2) + c_2(x_1 - x_2) + c_1(y_2 - y_1)}{a_1c_2 - a_2c_1} \quad (13)$$

$$l_c = \frac{k\alpha(a_1^2c_1 + a_2^2) - \gamma k(a_1c_1 + a_2c_2) + a_2(x_1 - x_2) + a_1(y_2 - y_1)}{a_1c_2 - a_2c_1}. \quad (14)$$

But $\hat{\mathbf{a}}$ and $\hat{\mathbf{c}}$ are UNIT VECTORS, so

$$l_a = \frac{k\alpha(a_1c_1 + a_2c_2) - \gamma k + c_2(x_1 - x_2) + c_1(y_2 - y_1)}{a_1c_2 - a_2c_1} \quad (15)$$

$$l_c = \frac{k\alpha - \gamma k(a_1c_1 + a_2c_2) + a_2(x_1 - x_2) + a_1(y_2 - y_1)}{a_1c_2 - a_2c_1}. \quad (16)$$

And the VECTOR coordinates of the point $\alpha : \beta : \gamma$ are then

$$\mathbf{x} = \mathbf{x}_1 + l_c \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} - k\gamma \begin{bmatrix} c_2 \\ -c_1 \end{bmatrix}. \quad (17)$$

Trilinear Line

A LINE is given in TRILINEAR COORDINATES by

$$l\alpha + m\beta + n\gamma = 0.$$

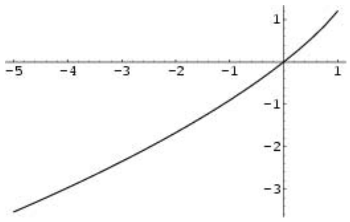
See also LINE, TRILINEAR COORDINATES

Trilinear Polar

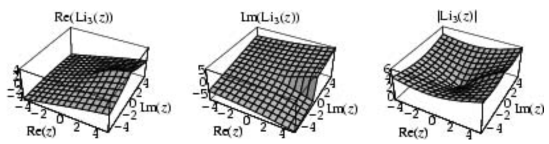
Given a TRIANGLE CENTER $X = l : m : n$, the line

$$l\alpha + m\beta + n\gamma = 0$$

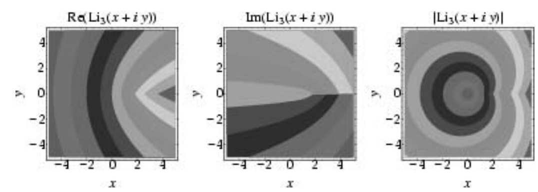
is called the trilinear polar of X^{-1} and is denoted L.



See also CHASLES'S POLARS THEOREM



Trillion



The word trillion denotes different numbers in American and British usage. In the American system, one trillion equals 10^{12}. In the British, French, and German systems, one trillion equals 10^{18}.

See also BILLION, LARGE NUMBER, MILLION

Trilogarithm

A special case of the POLYLOGARITHM $\mathrm{Li}_n(z)$ for $n = 3$. It is denoted $\mathrm{Li}_3(z)$, or sometimes $L_3(z)$. The notation $\mathrm{Li}_3(x)$ for the trilogarithm is unfortunately similar to that for the LOGARITHMIC INTEGRAL $\mathrm{Li}(x)$. Functional equations for the trilogarithm include

$$\mathrm{Li}_3(z) + \mathrm{Li}_3(-z) = \tfrac{1}{4}\,\mathrm{Li}_3\left(z^2\right) \tag{1}$$

$$\mathrm{Li}_3(-z) - \mathrm{Li}_3\left(-z^{-1}\right) = -\tfrac{1}{6}(\ln z)^3 - \tfrac{1}{6}\,\pi^2 \ln z \tag{2}$$

$$\mathrm{Li}_3(z) + \mathrm{Li}_3(1-z) + \mathrm{Li}_3\left(1 - z^{-1}\right)$$
$$= \zeta(3) + \tfrac{1}{6}(\ln z)^3 + \tfrac{1}{6}\pi^2 \ln z - \tfrac{1}{2}(\ln z)^2 \ln(1-z) \tag{3}$$

Analytic values for $\mathrm{Li}_3(x)$ include

$$\mathrm{Li}_3(-1) = -\tfrac{3}{4}\,\zeta(3) \tag{4}$$

$$\mathrm{Li}_3(0) = 0 \tag{5}$$

$$\mathrm{Li}_3\left(\tfrac{1}{2}\right) = \tfrac{1}{24}\left[-2\pi^2 \ln 2 + 4(\ln 2)^3 + 21\zeta(3)\right] \tag{6}$$

$$\mathrm{Li}_3(1) = \zeta(3) \tag{7}$$

$$\mathrm{Li}_3\left(\tfrac{1}{2}\left(3 - \sqrt{5}\right)\right) = \tfrac{4}{5}\,\zeta(3) + \tfrac{2}{3}(\ln \phi)^3 - \tfrac{2}{15}\,\pi^2 \ln \phi \tag{8}$$

where $\zeta(3)$ is APÉRY'S CONSTANT and ϕ is the GOLDEN RATIO.
Bailey *et al.* showed that

$$\tfrac{35}{2}\,\zeta(3) - \pi^2 \ln 2$$
$$= 36\,\mathrm{Li}_3\left(\tfrac{1}{2}\right) - 18\,\mathrm{Li}_3\left(\tfrac{1}{4}\right) - 4\,\mathrm{Li}_3\left(\tfrac{1}{8}\right) + \mathrm{Li}_3\left(\tfrac{1}{64}\right) \tag{9}$$

$$2(\ln 2)^3 - 7\zeta(3)$$
$$= -24\,\mathrm{Li}_3\left(\tfrac{1}{2}\right) + 18\,\mathrm{Li}_3\left(\tfrac{1}{4}\right) + 4\,\mathrm{Li}_3\left(\tfrac{1}{8}\right) - \mathrm{Li}_3\left(\tfrac{1}{64}\right) \tag{10}$$

$$10(\ln 2)^3 - 2\pi^2 \ln 2$$
$$= -48\,\mathrm{Li}_3\left(\tfrac{1}{2}\right) + 54\,\mathrm{Li}_3\left(\tfrac{1}{4}\right) + 12\,\mathrm{Li}_3\left(\tfrac{1}{8}\right) - 3\mathrm{Li}_3\left(\tfrac{1}{64}\right), \tag{11}$$

Trimagic Square

If replacing each number by its square or cube in a MAGIC SQUARE produces another MAGIC SQUARE, the square is said to be a trimagic square. Trimagic squares of order 32, 64, 81, and 128 are known. Tarry gave a method for constructing a trimagic square of order 128, Cazalas a method for trimagic squares of orders 64 and 81, and R. V. Heath a method for constructing an order 64 trimagic square which is different from Cazalas's (Kraitchik 1942).

Trimagic squares are also called TREBLY MAGIC SQUARES, and are 3-MULTIMAGIC SQUARES.

Trinoid

A MINIMAL SURFACE discovered by L. P. M. Jorge and W. Meeks III in 1983 with ENNEPER-WEIERSTRASS PARAMETERIZATION

$$f = \frac{1}{(\zeta^3 - 1)^2} \quad (1)$$

$$g = \zeta^2 \quad (2)$$

(Dickson 1990). Explicitly, it is given by

$$x = \Re\left[\frac{re^{i\theta}}{3(1 + re^{i\theta} + r^2e^{2i\theta})} - \frac{4\ln(re^{i\theta} - 1)}{9} + \frac{2\ln(1 + re^{i\theta} + r^2e^{2i\theta})}{9}\right] \quad (3)$$

$$y = -\tfrac{1}{9}\Im\left[\frac{-3re^{i\theta}(1 + re^{i\theta})}{r^3e^{3i\theta} - 1} + \frac{4\sqrt{3}(r^3e^{3i\theta} - 1)\tan^{-1}\left(\frac{1 + 2re^{i\theta}}{\sqrt{3}}\right)}{r^3e^{3i\theta} - 1}\right] \quad (4)$$

$$z = \Re\left[-\frac{2}{3} - \frac{2}{3(r^3e^{3i\theta} - 1)}\right], \quad (5)$$

for $0 \in [0,\ 2\pi)$ and $r \in [0,\ 4]$.

Trinomial

A POLYNOMIAL with three terms.

See also BINOMIAL, MONOMIAL, POLYNOMIAL

Trinomial Coefficient

A coefficient of the TRINOMIAL TRIANGLE. The trinomial coefficient $\binom{n}{k}_2$, with $n \geq 0$ and $-n \leq k \leq n$, is given by the coefficient of x^{n+k} in the expansion of $(1 + x + x^2)^n$. Therefore,

$$\binom{n}{-k}_2 = \binom{n}{k}_2.$$

Equivalently, the trinomial coefficients are defined by

$$(1 + x + x^{-1})^n = \sum_{j=-n}^{n} \binom{n}{j}_2 x^j. \quad (1)$$

The trinomial coefficients satisfy

$$\binom{m}{j}_2 = \binom{m-1}{j-1}_2 + \binom{m-1}{j}_2 + \binom{m-1}{j+1}_2. \quad (2)$$

An alternatives definition of the trinomial coefficients is as the coefficients in $(x + y + z)^n$ (Andrews 1990).

The (usual) trinomial coefficient is also given by the number of permutations of n symbols, each -1, 0, or 1, which sum to k. For example, there seven permutations of three symbols which sum to 0, {–1, 0, 1}, {–1, 1, 0}, {0, –1, 1}, {0, 0, 0}, and {0, 1, –1}, {1, –1, 0}, {1, 0, –1}, so $\binom{3}{0}_2 = 7$. Explicit formulas for $\binom{n}{k}_2$ are given by

$$\binom{n}{k}_2 = \sum_{j=0}^{n} \frac{n!}{j!(j+m)!(n-2j-m)!} \quad (3)$$

$$\binom{n}{k}_2 = \sum_{j=0}^{n} (-1)^j \binom{n}{j} \binom{2n-2j}{n-m-j} \quad (4)$$

(Andrews 1990).

The following table gives the first $\binom{n}{k}_2$ trinomial coefficients for $k = 0, 1, \ldots$ and $n = k, k+1, \ldots$.

k	Sloane	(n, k)-trinomial coefficients
0	Sloane's A002426	1, 1, 3, 7, 19, 51, 141, 393, 1107, 3139, 8953, ...
1	Sloane's A005717	1, 2, 6, 16, 45, 126, 357, 1016, 2907, 8350, ...
2	Sloane's A014531	1, 3, 10, 30, 90, 266, 784, 2304, ...
4		1, 5, 21, 77, 266, 882, 2850, 9042, ...
5		1, 6, 28, 112, 414, 1452, 4917, ...

Trinomial Identity

$$\left(x^2+axy+by^2\right)\left(t^2+atu+bu^2\right)=r^2+ars+bs^2, \quad (1)$$

where

$$r = xt - byu \quad (2)$$

$$s = yt + xu + ayu. \quad (3)$$

Trinomial Triangle

The Number Triangle obtained by starting with a row containing a single "1" and the next row containing three 1s and then letting subsequent row elements be computed by summing the elements above to the left, directly above, and above to the right:

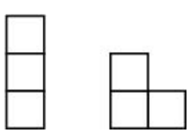
```
            1
         1  1  1
      1  2  3  2  1
   1  3  6  7  6  3  1
1  4  10 16 19 16 10 4  1
```

(Sloane's A027907). The nth row can also be obtained by expanding $(1+x+x^2)^n$ and taking coefficients:

$$(1+x+x^2)^0 = 1$$

$$(1+x+x^2)^1 = 1+x+x^2$$

$$(1+x+x^2)^2 = 1+2x+3x^2+2x^3+x^4$$



and so on.

Triomino

The two 3-Polyominoes are called triominoes, and are also known as the Trominoes. The left triomino above is "Straight," while the right triomino is called "right" or L-.

There is also a game called triomino consisting of 55 equilateral triangles, each containing three numbers from 0 to 5 at each vertex. Every combination of tiles is in the game, although those tiles with three different values are allowed to be arranged only in clockwise-increasing order.

Triple-Free Set

A SET of POSITIVE integers is called weakly triple-free if, for any integer x, the SET $\{x, 2x, 3x\} \not\subseteq S$. It is called strongly triple-free if $x \in S$ IMPLIES $2x \notin S$ and $3x \notin S$ (i.e., the set is both DOUBLE-FREE and triple-free). For example, the subsets of $\{1, 2, 3\}$ which are weakly triple-free are $\emptyset$, $\{1\}$, $\{1, 2\}$, $\{2\}$, $\{2, 3\}$, and $\{3\}$, while $\{1, 2, 3\}$ and $\{1, 3\}$ are not. Of these weakly triple-free sets, $\emptyset$, $\{1\}$, $\{2\}$, $\{2, 3\}$, and $\{3\}$ are also strongly triple-free.

The number of weakly triple-free subsets of $\{1, 2, \ldots, n\}$ for $n=1$, 2, ... are 2, 4, 6, 12, 24, 36, 72, 144, 240, 480, ... (Sloane's A050293). The number of strongly triple-free subsets for $n=1$, 2, ... are 2, 3, 5, 8, 16, 24, 48, 76, 132, ... (Sloane's A050295).

Define

$$\begin{aligned} p(n) &= \max\{|S| : S \subset (1, 2, \ldots, n\} \\ &\quad \text{is weakly triple-free}\} \\ q(n) &= \max\{|S| : S \subset (1, 2, \ldots, n\} \\ &\quad \text{is strongly triple-free}\}, \end{aligned}$$

where $|S|$ denotes the CARDINAL NUMBER of (number of members in) S. Then for $n=1$, 2, ..., $p(n)$ is given by 1, 2, 2, 3, 4, 4, 5, 6, 7, 8, 9, 9, 10, 11, 11, ... (Sloane's A050294), and $q(n)$ by 1, 1, 2, 2, 3, 4, 5, 5, 6, 6, 7, 7, 8, 8, 9, ... (Sloane's A050296). Asymptotic formulas are given by

$$\lim_{n\to\infty} \frac{p(n)}{n} \geq \frac{4}{5}$$

and

$$\lim_{n\to\infty} \frac{q(n)}{n} = 0.6134752692\ldots$$

(Finch).

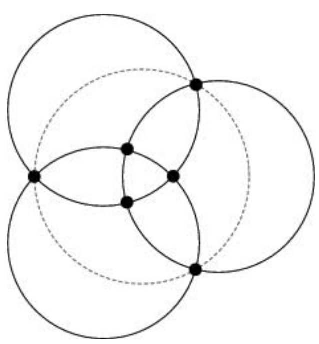
Triplicate-Ratio Circle

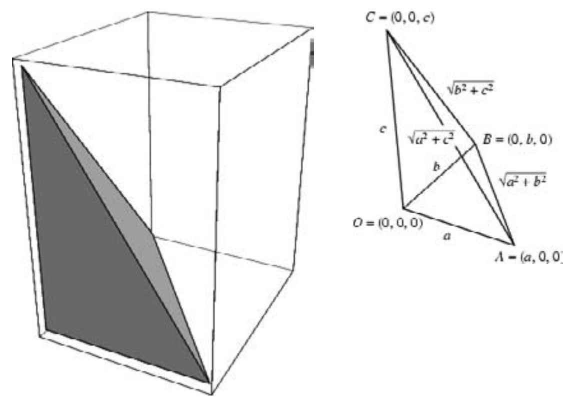


LEMOINE CIRCLE

Triquetra

This entry contributed by DANA MACKENZIE

A "triquetra" is a figure consisting of three circular arcs of equal radius, and has seen extensive use in heraldry (i.e., coats of arms), specifically in the case of the so-called BORROMEAN RINGS. The term "Triquetra theorem" was coined by Mackenzie (1992) to describe the geometric theorem that if three circles are concurrent at a single point, then the other three intersection points lie on a circle of the same radius as the first three. This version was first proved in 1916.



Mackenzie (1992) generalized this theorem to the case where the three circles do not coincide. In this case, they form six intersection points, and if you partition the points into any two groups of three and look at the CIRCUMRADII of the points in those groups, there is a nice formula relating them to the radii of the triquetra circles. This formula has some pretty geometric consequences (or "porisms"). Ultimately, the triquetra theorem turns out to be closely related to PONCELET'S PORISM.

See also BORROMEAN RINGS, CIRCLE-CIRCLE INTERSECTION, CIRCULAR TRIANGLE, HARUKI'S THEOREM, PONCELET'S PORISM, REULEAUX TRIANGLE, VENN DIAGRAM

Trirectangular Tetrahedron

A TETRAHEDRON having a TRIHEDRON all of the face angles of which are right angles. The face opposite the vertex of the right angles is called the base. If the edge lengths bounding the trihedral angle are a, b, and c, then the side lengths of the base are given by $\sqrt{a^2+b^2}$, $\sqrt{a^2+c^2}$, and $\sqrt{b^2+c^2}$, and so has SEMIPERIMETER

$$s=\tfrac{1}{2}\Big(\sqrt{a^2+b^2}+\sqrt{a^2+c^2}+\sqrt{b^2+c^2}. \qquad (1)$$

The VOLUME of the trirectangular tetrahedron is

$$V=\tfrac{1}{6}\,abc. \qquad (2)$$

Using HERON'S FORMULA, the SURFACE AREA is therefore

$$S=\tfrac{1}{2}\Big(ab+ac+bc+\sqrt{a^2b^2+a^2c^2+b^2c^2}\Big). \qquad (3)$$

Let Δ_{XYZ} be the AREA of the triangle with vertices X, Y, and Z. The remarkable DE GUA'S THEOREM

$$\Delta_{ABC}^2=\Delta_{OAB}^2+\Delta_{OAC}^2+\Delta_{OAC}^2. \qquad (4)$$

then follows from the identity

$$s\Big(s-\sqrt{a^2+b^2}\Big)\Big(s-\sqrt{a^2+c^2}\Big)\Big(s-\sqrt{b^2+c^2}\Big)$$
$$=\tfrac{1}{4}\big(a^2b^2+a^2c^2+b^2c^2\big), \qquad (5)$$

with s defined by (1).

Trisection

Angle trisection is the division of an *arbitrary* ANGLE into three equal ANGLES. It was one of the three GEOMETRIC PROBLEMS OF ANTIQUITY for which solutions using only COMPASS and STRAIGHTEDGE were sought. The problem was algebraically proved impossible by Wantzel (1836).

Although trisection is not possible for a general ANGLE using a Greek construction, there are some specific angles, such as $\pi/2$ and π radians (90° and 180°, respectively), which *can* be trisected. Furthermore, some ANGLES are geometrically trisectable, but cannot be constructed in the first place, such as $3\pi/7$ (Honsberger 1991). In addition, trisection of an arbitrary angle *can* be accomplished using a *marked* RULER *(a* NEUSIS CONSTRUCTION*) as illustrated above (Courant and Robbins 1996).*

An approximate trisection is described by Steinhaus (Wazewski 1945, Steinhaus 1983, p. 7). Given an angle $\theta = \angle AOB$, draw the bisector $\theta/2 = \angle AOC$, with $OC = OA = OB = 1$, then divide BC such that $BD = 2CD$. From the SAS THEOREM ΔCOB, the length s is given by the formula

$$b^2 = a^2 + c^2 - 2ac\cos B \tag{1}$$

with $s = b$, $a = c = 1$, $B = \theta/2$,

$$s = \sqrt{2 - 2\cos\left(\tfrac{1}{2}\theta\right)} = 2\sqrt{\frac{1 - \cos\left(\tfrac{1}{2}\theta\right)}{2}}$$
$$= 2\sin\left(\tfrac{1}{4}\theta\right), \tag{2}$$

and L is then

$$L = \tfrac{2}{3}s = \tfrac{4}{3}\sin\left(\tfrac{1}{4}\theta\right). \tag{3}$$

The angle φ can then be computed from the formula

$$\varphi = \sin^{-1}\left(\frac{a\sin B}{\sqrt{a^2 + c^2 - 2ac\cos B}}\right) \tag{4}$$

to obtain

$$\varphi = \sin^{-1}\left[\frac{\sin\left(\tfrac{1}{2}\theta\right)}{\sqrt{2 - 2\cos\left(\tfrac{1}{2}\theta\right)}}\right]$$
$$= \sin^{-1}\left[\frac{2\sin\left(\tfrac{1}{4}\theta\right)\cos\left(\tfrac{1}{4}\theta\right)}{2\sin\left(\tfrac{1}{4}\theta\right)}\right]$$
$$= \sin^{-1}\left[\cos\left(\tfrac{1}{4}\theta\right)\right]. \tag{5}$$

ϕ is then given by the formula for an SAS triangle

ΔBOD

$$\phi = \sin^{-1}\left(\frac{L \sin \varphi}{\sqrt{1 + L^2 - 2L \cos \varphi}}\right)$$
$$= \sin^{-1}\left[\frac{\frac{2}{3}\sin\left(\frac{1}{2}\theta\right)}{1 - \frac{8}{9}\sin^2\left(\frac{1}{4}\theta\right)}\right]$$
$$= \sin^{-1}\left[\frac{6\sin\left(\frac{1}{2}\theta\right)}{5 + 4\cos\left(\frac{1}{2}\theta\right)}\right]. \quad (6)$$

The Maclaurin series is then

$$\phi = \tfrac{1}{3}\theta + \tfrac{7}{648}\theta^3 + \tfrac{19}{31104}\theta^5 + \cdots \approx \tfrac{1}{3}\theta \quad (7)$$

to a very good approximation.

An ANGLE can also be divided into three (or any WHOLE NUMBER) of equal parts using the QUADRATRIX OF HIPPIAS or TRISECTRIX.

See also ANGLE BISECTOR, MACLAURIN TRISECTRIX, QUADRATRIX OF HIPPIAS, TRISECTRIX

Trisectrix

A curve which can be used to trisect an angle. Although an arbitrary angle cannot be trisected using only COMPASS and STRAIGHTEDGE (i.e., according to the strict rules of Greek GEOMETRIC CONSTRUCTION), it can be trisected using certain curves (which are assumed to have been constructed using some other means).

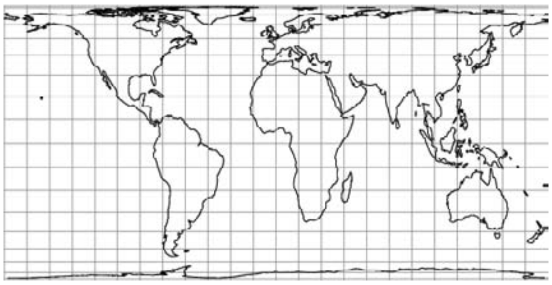
Triskaidecagon



TRIDECAGON

Triskaidekaphobia

The number 13 is traditionally associated with bad luck. This superstition leads some people to fear or avoid anything involving this number, a condition known as triskaidekaphobia. Triskaidekaphobia leads to interesting practices such as the numbering of floors as 1, 2, ..., 11, 12, 14, 15, ..., *omitting the number 13,* in many high-rise hotels.

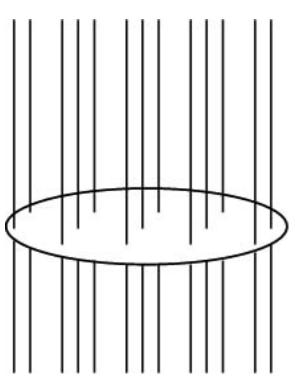
BINARY TREE

Trivial

Related to or being the mathematically most simple case. More generally, the word "trivial" is used to describe any result which requires little or no effort to derive or prove. The word originates from the Latin TRIVIUM, which was the lower division of the seven liberal arts in medieval universities (cf. QUADRIVIUM).

According to the Nobel Prize-winning physicist Richard Feynman (Feynman 1997), mathematicians designate any THEOREM as "trivial" once a proof has been obtained–no matter how difficult the theorem was to prove in the first place. There are therefore exactly two types of true mathematical propositions: trivial ones, and those which have not yet been proven.



The opposite of a trivial theorem is a "DEEP THEOREM."

See also DEEP THEOREM, DEGENERACY, FRIVOLOUS THEOREM OF ARITHMETIC, PROOF, THEOREM, TRIVIUM

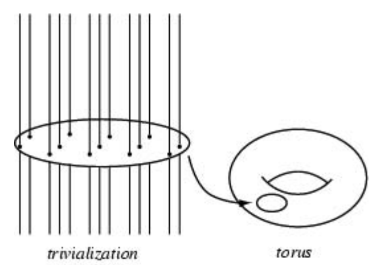
Trivial Basis



Trivial Group

The trivial group is the unique GROUP containing exactly one element. That is, it is $G=\{e\}$, where e is the IDENTITY ELEMENT (so that $ee=e$).

See also CYCLIC GROUP, FINITE GROUP, GROUP, IDENTITY ELEMENT

Trivialization

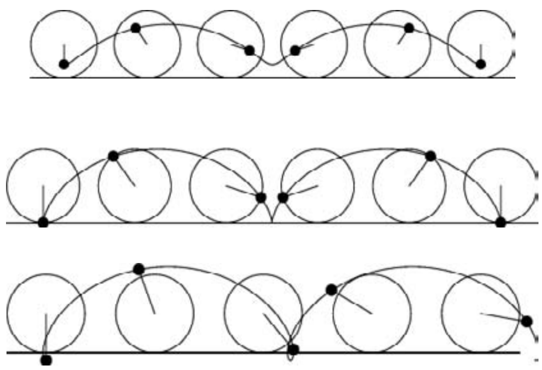
Over a small NEIGHBORHOOD U of a MANIFOLD, a VECTOR BUNDLE is spanned by the local sections defined on U. For example, in a COORDINATE CHART U with coordinates $(x_1, \ldots, x_n)$, every smooth VECTOR FIELD can be written as a sum $\Sigma_i f_i\, \partial/\partial x_i$ where f_i are smooth functions. The n vector fields $\partial/\partial x_i$ span the space of vector fields, considered as a MODULE over the RING of smooth real-valued functions. On this COORDINATE CHART U, the tangent bundle can be written $U \times \mathbb{R}^n$. This is a trivialization of the tangent bundle.

trivialization of a line bundle on a torus

In general, a vector bundle of RANK r is spanned LOCALLY by r independent SECTIONS. Every point has a NEIGHBORHOOD U and r sections defined on U, such that over every point in U the fibers are spanned by those r sections.

Similarly, for a FIBER BUNDLE, near every point $p \in M$, there is a neighborhood U such that the bundle over U is $U \times F$, where F is the fiber.

A bundle is a set of trivializations that cover the base manifold. The trivializations are put together to form a bundle with its TRANSITION FUNCTIONS.



See also BUNDLE, FIBER BUNDLE, MANIFOLD, TRANSITION FUNCTION, VECTOR BUNDLE

Trivium

A word derived from the Latin roots *tri-* (three) and *via* (ways, roads), therefore a crossing of three roads. In medieval universities, the trivium consisted of the three subjects in the lower division of the seven liberal arts: grammar, rhetoric, and logic. The word TRIVIAL derives from the fact that the trivium contained the least complicated studies.

See also QUADRIVIUM, TRIVIAL

Trochoid

The curve described by a point at a distance b from the center of a rolling CIRCLE of RADIUS a.

$$x = a\phi - b \sin \phi$$

$$y = a - b \cos \phi.$$

If $b < a$, the curve is a CURTATE CYCLOID. If $b = a$, the curve is a CYCLOID. If $b > a$, the curve is a PROLATE CYCLOID.

See also CURTATE CYCLOID, CYCLOID, EPITROCHOID, HYPOTROCHOID, PROLATE CYCLOID

Tromino

TRIOMINO

Trott's Constant

The constant $x = 0.0108410151223111361511 29\ldots$ whose decimal digits are equal to the constant's own CONTINUED FRACTION [0, 1, 0, 8, 4, 1, 0, 1, 5, ...]. This constant was discovered by M. Trott of Wolfram Research in 1999. It appears to be unique, and all attempts to find other such numbers have failed.

See also CONTINUED FRACTION

True

A statement which is rigorously known to be correct. A statement which is not true is called FALSE, although certain statements can be proved to be rigorously UNDECIDABLE within the confines of a given set of assumptions and definitions. Regular two-valued LOGIC allows statements to be only true or FALSE, but FUZZY LOGIC treats "truth" as a continuum which can have any value between 0 and 1. The symbol Υ is sometimes used to denote "true," although "T" is more commonly used in TRUTH TABLES.

See also ALETHIC, BOOLEANS, FALSE, FUZZY LOGIC, LOGIC, TRUTH TABLE, UNDECIDABLE

Truncatable Prime

Call a number n containing no zeros right truncatable if n and all numbers obtained by successively removing the rightmost DIGIT are PRIME. There are 83 right truncatable primes in base 10. The first few are 2, 3, 5, 7, 23, 29, 31, 37, 53, 59, 71, 73, 79, 233, 239, 293, 311, 313, 317, 373, 379, 593, 599, ... (Sloane's A024770), the largest being 73,939,133 (Angell and Godwin 1977). The numbers of left prime strings less than 10, 10^2, 10^3, ... are 4, 9, 14, 16, 15, 12, 8, and 5 (Sloane's A050986; Rivera puzzle 70).

If zeros are permitted, the sequence of right truncatable primes are 2, 3, 5, 7, 13, 17, 23, 37, 43, 47, 53, 67, 73, 83, 97, 103, 107, 113, 137, 167, 173, 197, 223, 283, 307, ... (Sloane's A033664).

Similarly, call a number n left truncatable if n and all numbers obtained by successively removing the leftmost DIGIT are PRIME. There are 4260 right prime strings in base 10 when the digit zero is not allowed (otherwise, if zeros are permitted, the sequence is infinite). The first few are 2, 3, 5, 7, 13, 17, 23, 37, 43, 47, 53, 67, 73, 83, 97, 113, 137, 167, 173, ... (Sloane's A024785), with the largest being 357,686,312,646,216,567,629,137 (Angell and Godwin 1977, Baillie 1995). The numbers of right prime strings less than 10, 10^2, 10^3, ... are 4, 11, 39, 99, 192, 326, 429, ... (Sloane's A050987; Rivera puzzle 70).

J. Shallit has shown that in base 10, there is a finite, minimal list of primes that do not have any other primes as substrings (where digits do *not* need to be consecutive). This result is a special case of a much more general theorem, whose proof is unfortunately nonconstructive.

Call an n-digit prime p_n (with $n \geq 2$) is a restricted left truncatable prime if

1. If the leftmost digit of p_i is deleted, a prime number p_{i-1} is obtained for $2 \leq i \leq n$, and
2. No prime with $n+1$ digits can have its leftmost digit removed to produce p_n.

Kahan and Weintraub (1998) dub such primes "Henry VIII primes." Restricted left truncatable primes p_n are therefore a subset of left truncatable primes for which there are no left truncatable primes of length $n+1$ having the same n last digits as p_n. There are a total of 1440 such primes, and the first few are 773, 3373, 3947, 4643, 5113, 6397, 6967, 7937, ... (Sloane's A055522), the largest being 357686312646216567629137 (Kahan and Weintraub 1998).

Truncated Cone

CONICAL FRUSTUM

Truncated Cube

The 14-faced ARCHIMEDEAN SOLID A_9 with faces $8\{3\}+6\{8\}$. It is also UNIFORM POLYHEDRON U_9 and Wenninger model W_8. It has SCHLÄFLI SYMBOL t{4, 3} +2668511278169369879040000S^{12} and WYTHOFF SYMBOL 23|4.

The DUAL POLYHEDRON of the truncated cube is the TRIAKIS OCTAHEDRON. The INRADIUS r of the dual, MIDRADIUS ρ of the solid and dual, and CIRCUMRADIUS R of the solid for $a=1$ are

$$r = \tfrac{1}{17}\left(5+2\sqrt{2}\right)\sqrt{7+4\sqrt{2}} \approx 1.63828$$

$$\rho = \tfrac{1}{2}\left(2+\sqrt{2}\right) \approx 1.70711$$

$$R = \tfrac{1}{2}\sqrt{7+4\sqrt{2}} \approx 1.77882.$$

The distances from the center of the solid to the centroids of the triangular and octagonal faces are

$$r_3 = \tfrac{1}{2}\sqrt{\tfrac{1}{3}\left(17+12\sqrt{2}\right)} \tag{1}$$

$$r_8 = \tfrac{1}{2}\left(1+\sqrt{2}\right). \tag{2}$$

The SURFACE AREA and VOLUME are

$$S = 2\left(6+6\sqrt{2}+2\sqrt{3}\right) \tag{3}$$

$$V = \tfrac{1}{3}\left(21+14\sqrt{2}\right). \tag{4}$$

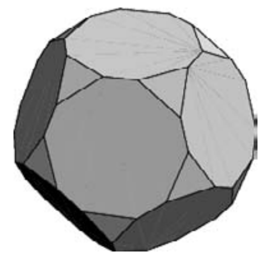
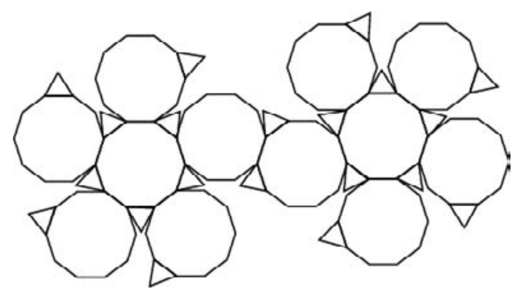
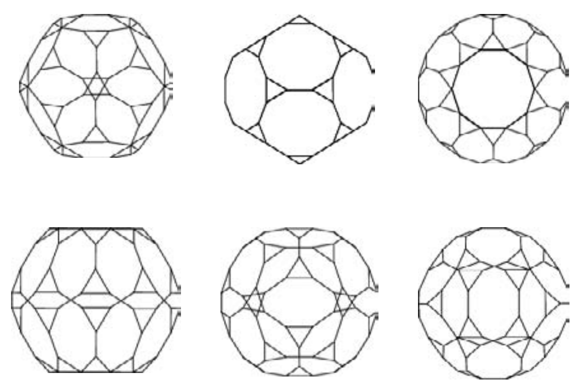
Truncated Dodecadodecahedron



The UNIFORM POLYHEDRON U_{59}, also called the QUASI-TRUNCATED DODECAHEDRON, whose DUAL POLYHEDRON is the MEDIAL DISDYAKIS TRIACONTAHEDRON. It has SCHLÄFLI SYMBOL t' $\left\{\begin{matrix}\frac{5}{2}\\ 5\end{matrix}\right\}$ and WYTHOFF SYMBOL $2\ \frac{5}{3}\ |\ 5$. Its faces are $12\{10\} + 30\{4\} + 12\{\frac{10}{3}\}$. Its CIRCUMRADIUS for $a = 1$ is



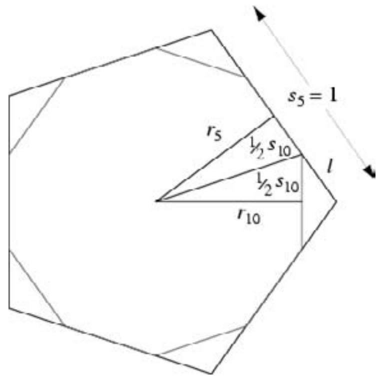
$$R = \tfrac{1}{2}\sqrt{11}.$$



References

Wenninger, M. J. *Polyhedron Models.* Cambridge, England: Cambridge University Press, pp. 152–153, 1989.

Truncated Dodecahedron



The 32-faced ARCHIMEDEAN SOLID A_{10} with faces $20\{3\} + 12\{10\}$. It is also UNIFORM POLYHEDRON U_{26} and Wenninger model W_{10}. It has SCHLÄFLI SYMBOL t{5, 3} and WYTHOFF SYMBOL $2\ 3\ |\ 5$.

The DUAL POLYHEDRON is the TRIAKIS ICOSAHEDRON.

To construct the truncated dodecahedron by TRUNCATION, note that we want the INRADIUS r_{10} of the truncated pentagon to correspond with that of the original pentagon, r_5, of unit side length $s_5 = 1$. This means that the side lengths s_{10} of the decagonal faces in the truncated dodecahedron satisfy

$$\tfrac{1}{2} s_5 \cot\left(\frac{\pi}{5}\right) = \tfrac{1}{2} s_{10} \cot\left(\frac{\pi}{10}\right), \tag{1}$$

giving

$$s_{10} = \tfrac{1}{5}\sqrt{5}s_5 = \tfrac{1}{5}\sqrt{5}. \tag{2}$$

The length of the corner which is chopped off is therefore given by

$$l = \tfrac{1}{2} - \tfrac{1}{2} s_{10} = \tfrac{1}{10}\left(5 - \sqrt{5}\right). \tag{3}$$

The INRADIUS r of the dual, MIDRADIUS p_i of the solid and dual, and CIRCUMRADIUS R of the solid for $a = 1$ are

$$r = \tfrac{5}{2}\sqrt{\tfrac{1}{61}\left(41 + 18\sqrt{5}\right)} \approx 2.88526 \tag{4}$$

$$\rho = \tfrac{1}{4}\left(5 + 3\sqrt{5}\right) \approx 2.92705 \tag{5}$$

$$R = \tfrac{1}{4}\sqrt{74 + 30\sqrt{5}} \approx 2.96945. \tag{6}$$

The distances from the center of the solid to the centroids of the triangular and decagonal faces are given by

$$r_3 = \tfrac{1}{12}\sqrt{3}\left(9 + 5\sqrt{5}\right) \tag{7}$$

$$r_{10} = \tfrac{1}{2}\sqrt{\tfrac{1}{2}\left(25 + 11\sqrt{5}\right)}. \tag{8}$$

The SURFACE AREA and VOLUME are

$$S = 5\left(\sqrt{3} + 6\sqrt{5 + 2\sqrt{5}}\right) \tag{9}$$

$$V = \tfrac{5}{12}\left(99 + 47\sqrt{5}\right). \tag{10}$$

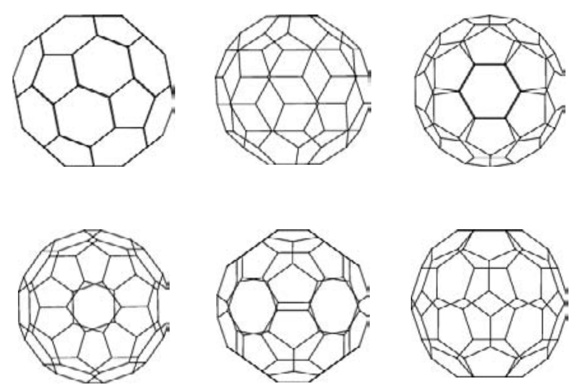
Great Truncated Icosahedron



Truncated Hexahedron

Truncated Cube

Truncated Icosahedron

The 32-faced Archimedean solid A_{11} corresponding to the facial arrangement $20\{6\} + 12\{5\}$. It is the shape used in the construction of soccer balls, and it was also the configuration of the lenses used for focusing the explosive shock waves of the detonators in the Fat Man atomic bomb (Rhodes 1996, p. 195). The truncated icosahedron has 60 vertices, and is also the C_{60} structure of pure carbon known as buckyballs (a.k.a. fullerenes). The truncated icosahedron is uniform polyhedron U_{25} and Wenninger model W_9. It has Schläfli symbol t{3, 5} and Wythoff symbol 2 5 | 3.

The dual polyhedron of the truncated icosahedron is the pentakis dodecahedron. The inradius r of the dual, midradius ρ of the solid and dual, and circumradius R of the solid for $a = 1$ are

$$r = \tfrac{9}{2}\sqrt{\tfrac{1}{109}\left(17+6\sqrt{5}\right)} \approx 2.37713$$

$$\rho = \tfrac{3}{4}\left(1+\sqrt{5}\right) \approx 2.42705$$

$$R = \tfrac{1}{4}\sqrt{58+18\sqrt{5}} \approx 2.47802.$$

The distances from the center of the solid to the centroids of the pentagonal and hexagonal faces are given by

$$r_5 = \tfrac{1}{2}\sqrt{\tfrac{1}{10}\left(125+41\sqrt{5}\right)} \qquad (1)$$

$$r_6 = \tfrac{1}{2}\sqrt{\tfrac{3}{2}\left(7+3\sqrt{5}\right)}. \qquad (2)$$

The SURFACE AREA and VOLUME are

$$S = 3\left(10\sqrt{3}+\sqrt{5}\sqrt{5+2\sqrt{5}}\right) \qquad (3)$$

$$V = \tfrac{1}{4}\left(125+43\sqrt{5}\right). \qquad (4)$$

Truncated Icosahedron-Pentakis Dodecahedron Compound

The POLYHEDRON COMPOUND of the TRUNCATED ICOSAHEDRON and its dual, the PENTAKIS DODECAHEDRON. The compound can be constructed from a TRUNCATED ICOSAHEDRON of unit edge length by midpoint CUMULATION with heights

$$h_5 = \tfrac{1}{38}\sqrt{\tfrac{1}{10}\left(305+131\sqrt{5}\right)} \qquad (1)$$

$$h_6 = \tfrac{1}{4}\sqrt{3}\left(\sqrt{5}-3\right). \qquad (2)$$

The resulting solid has edge lengths

$$s_1 = \tfrac{1}{2} \qquad (3)$$

$$s_2 = \tfrac{3}{76}\left(7+5\sqrt{5}\right) \qquad (4)$$

$$s_3 = \tfrac{1}{4}\left(1+\sqrt{5}\right) \qquad (5)$$

$$s_4 = \tfrac{1}{2}\sqrt{3} \qquad (6)$$

$$s_5 = \tfrac{3}{4}\left(\sqrt{5}-1\right), \qquad (7)$$

CIRCUMRADIUS

$$R = \tfrac{3}{2}\sqrt{3}, \qquad (8)$$

SURFACE AREA S given by the fourth largest positive root of

$$\begin{aligned}&514101603076499666761095163949371719360351562 5\\ &-929177438500451011816177966728149414062500 0S^2\\ &+634192611426319914761893302533203125400 00S^4\\ &-21626183555239961438398026562500000000S^6\\ &+4069907058882620169449676000000000S^8\\ &-437859794226826493167680000000S^{10}\\ &+26685112781693698790400000S^{12}\\ &-854208336788692992 00S^{14}\\ &+1113034787454976S^{16}\end{aligned} \qquad (9)$$

and VOLUME

$$V = \tfrac{5}{152}\left(1477+162\sqrt{5}\right). \qquad (10)$$

Truncated Icosidodecahedron

GREAT RHOMBICOSIDODECAHEDRON (ARCHIMEDEAN)

Truncated Octahedral Number

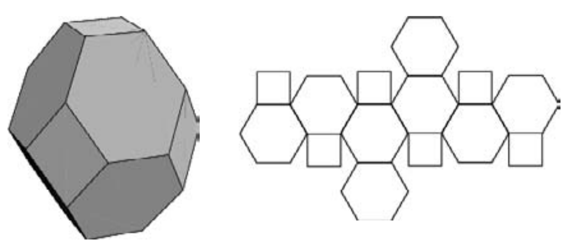
A FIGURATE NUMBER which is constructed as an OCTAHEDRAL NUMBER with a SQUARE PYRAMID re-

moved from each of the six VERTICES,

$$TO_n = O_{3n-2} - 6P_{n-1} = 16n^3 - 33n^2 + 24n - 6,$$

where O_n is an OCTAHEDRAL NUMBER and P_n is a SQUARE PYRAMIDAL NUMBER. The first few are 1, 38, 201, 586, ... (Sloane's A005910). The GENERATING FUNCTION for the truncated octahedral numbers is

$$\frac{x(6x^3 + 55x^2 + 34x + 1}{(x-1)^4} = x + 38x^2 + 201x^3 + \ldots$$



See also OCTAHEDRAL NUMBER, SQUARE PYRAMIDAL NUMBER

Truncated Octahedron

The 14-faced ARCHIMEDEAN SOLID A_{12}, also known as the MECON, with faces $8\{6\} + 6\{4\}$. It is also UNIFORM POLYHEDRON U_8 and Wenninger model W_7. It has SCHLÄFLI SYMBOL t{3, 4} and WYTHOFF SYMBOL 2 4 | 3.

The DUAL POLYHEDRON of the truncated octahedron is the TETRAKIS HEXAHEDRON. The truncated octahedron has the O_h OCTAHEDRAL GROUP of symmetries. The form of the fluorite (CaF_2) resembles the truncated octahedron (Steinhaus 1983, pp. 207–208).

The solid of unit edge length can be formed from an OCTAHEDRON of edge length 3 via TRUNCATION by removing six SQUARE PYRAMIDS, each with edge slant height $s = 1$, base $a = 1$ on a side, and height h. The height and base area of the SQUARE PYRAMID are then

$$h = \sqrt{s^2 - \tfrac{1}{4}a^2 \csc^2\left(\frac{\pi}{n}\right)} = \tfrac{1}{2}\sqrt{2}a \tag{1}$$

$$A_b = a^2. \tag{2}$$

The SURFACE AREA of the truncated octahedron is

$$S = 6 + 12\sqrt{3}. \tag{3}$$

The VOLUME of the truncated octahedron is then given by the VOLUME of the OCTAHEDRON

$$V_{\text{octahedron}} = \tfrac{1}{3}\sqrt{2}s^3 = 9\sqrt{2}a^3 \tag{4}$$

minus six times the volume of the SQUARE PYRAMID,

$$V = V_{\text{octahedron}} - 6\left(\tfrac{1}{3}A_b h\right) = \left(9\sqrt{2} - \sqrt{2}\right)a^3$$
$$= 8\sqrt{2}a^3. \tag{5}$$

The truncated octahedron is a SPACE-FILLING POLYHEDRON (Steinhaus 1983, pp. 187–190 and 207).

The INRADIUS r of the dual, MIDRADIUS ρ of the solid and dual, and CIRCUMRADIUS R of the solid for $a = 1$ are

$$r = \tfrac{9}{20}\sqrt{10} \approx 1.42302 \tag{6}$$

$$\rho = \tfrac{3}{2} = 1.5 \tag{7}$$

$$R = \tfrac{1}{2}\sqrt{10} \approx 1.58114. \tag{8}$$

The distances from the center of the solid to the centroids of the square and hexagonal faces are given by

$$r_4 = \sqrt{2} \tag{9}$$

$$r_6 = \tfrac{1}{2}\sqrt{6}. \tag{10}$$

Truncated Pyramid

PYRAMIDAL FRUSTUM

Truncated Square Pyramid

The truncated square pyramid is a special case of a PYRAMIDAL FRUSTUM for a SQUARE PYRAMID. Let the base and top side lengths of the truncated pyramid be a and b, and let the height be h. Then the VOLUME of the solid is

$$V = \tfrac{1}{3}(a^2 + ab + b^2)h.$$

This FORMULA was known to the Egyptians ca. 1850 BC. The Egyptians cannot have proved it without calculus, however, since Dehn showed in 1900 that no proof of this equation exists which does not rely on the concept of continuity (and therefore some form of INTEGRATION).

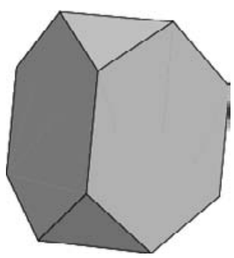
See also FRUSTUM, PYRAMID, PYRAMIDAL FRUSTUM, SQUARE PYRAMID

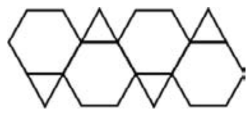
Truncated Tetrahedral Number

A FIGURATE NUMBER constructed by taking the $(3n-2)$th TETRAHEDRAL NUMBER and removing the $(n-1)$th TETRAHEDRAL NUMBER from each of the four corners,

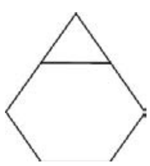
$$\mathrm{Ttet}_n \equiv \mathrm{Te}_{3n-3} - 4\mathrm{Te}_{n-1} = \tfrac{1}{6}n(23n^2 - 27n + 10).$$

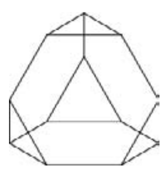
The first few are 1, 16, 68, 180, 375, ... (Sloane's A005906). The GENERATING FUNCTION for the truncated tetrahedral numbers is

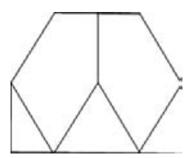


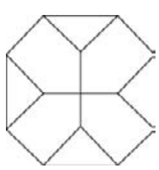


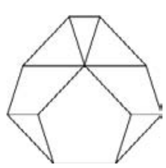
$$\frac{x(10x^2+12x+1)}{(x-1)^4} = x + 16x^2 + 68x^3 + 180x^4 + \ldots.$$











References

Truncated Tetrahedron

The ARCHIMEDEAN SOLID A_{13} with faces $4\{3\}+4\{6\}$. It is also UNIFORM POLYHEDRON U_2 and Wenninger model W_6. It has SCHLÄFLI SYMBOL t{3, 3} and WYTHOFF SYMBOL 2 3 | 3.

The dual of the truncated tetrahedron is the TRIAKIS TETRAHEDRON. The INRADIUS r of the dual, MIDRADIUS ρ of the solid and dual, and CIRCUMRADIUS R of the solid for $a = 1$ are

$$r = \tfrac{9}{44}\sqrt{22} \approx 0.95940$$

$$\rho = \tfrac{3}{4}\sqrt{2} \approx 1.06066$$

$$R = \tfrac{1}{4}\sqrt{22} \approx 1.17260$$

The distances from the center of the solid to the centroids of the triangular and hexagonal faces are given by

$$r_3 = \tfrac{1}{12}\sqrt{6} \qquad (1)$$

$$r_6 = \tfrac{1}{4}\sqrt{6}. \qquad (2)$$

The SURFACE AREA and VOLUME are

$$S = 7\sqrt{3} \qquad (3)$$

$$V = \tfrac{23}{12}\sqrt{2}. \qquad (4)$$

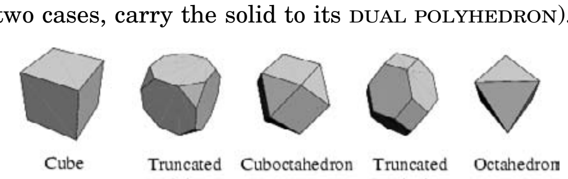
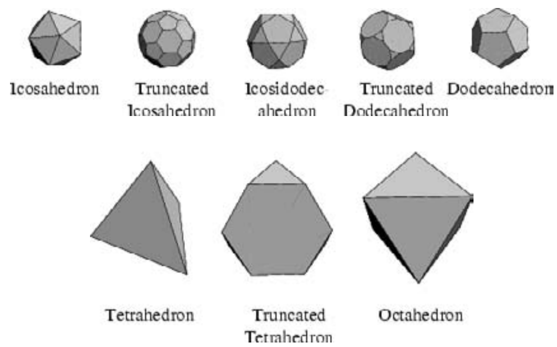
Truncated Tetrahedron-Triakis Tetrahedron Compound

The compound of a TRUNCATED TETRAHEDRON and its dual, the TRIAKIS TETRAHEDRON. The compound can be constructed from a TRUNCATED OCTAHEDRON of unit edge length by midpoint CUMULATION with heights

$$h_3 = \tfrac{1}{30}\sqrt{6} \qquad (1)$$



$$h_6 = \tfrac{1}{2}\sqrt{6}. \qquad (2)$$



See also CUMULATION, POLYHEDRON COMPOUND, TRIAKIS TETRAHEDRON, TRUNCATED TETRAHEDRON

Truncation

The removal of portions of SOLIDS falling outside a set of symmetrically placed planes. The dual operation consists of replacing facial polygons with pyramids, and is sometimes known as CUMULATION.

The five PLATONIC SOLIDS belong to one of the following three truncation series (which, in the first two cases, carry the solid to its DUAL POLYHEDRON).

See also CUMULATION, DÜRER'S SOLID, PYRAMID, STELLATION, TRUNCATED CUBE, TRUNCATED DODECAHEDRON, TRUNCATED ICOSAHEDRON, TRUNCATED OCTAHEDRON, TRUNCATED TETRAHEDRON, VERTEX FIGURE

Truth Table

A truth table is a 2-D array with $n+1$ columns. The first n columns correspond to the possible values of n inputs, and the last column to the operation being performed. The rows list all possible combinations of inputs together with the corresponding outputs. For example, the following truth table shows the result of the binary AND operator acting on two inputs A and B, each of which may be true or false.

A	B	$A \wedge B$
F	F	F
F	T	F
T	F	F
T	T	T

The following *Mathematica* code can be used to generate a truth table for n levels of operator op.

```
TruthTable[op_, n_] := Module[
   {
      l  =  Flatten[Outer[List,  Sequence  @@
Table[{True, False}, {n}]], n - 1],
    a  =  Array[A, n]
   },
   DisplayForm[
    GridBox[Prepend[Append[#, op @@ #] & /@ l,
Append[a, op @@ a]],       RowLines -> True,
ColumnLines -> True]
   ]
  ]
```

Tschebyshev System

HAAR CONDITION

Tschirnhausen Cubic Caustic

The CAUSTIC of the TSCHIRNHAUSEN CUBIC taking the RADIANT POINT as the pole is NEILE'S PARABOLA.

Tschirnhausen Cubic

The Tschirnhausen cubic is a plane curve given by the polar equation

$$r = a\sec^3\left(\tfrac{1}{3}\theta\right) \tag{1}$$

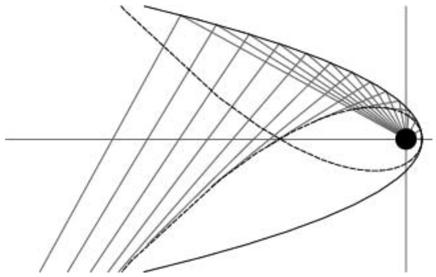
or parametric equation

$$x = a(1-3t^2) \tag{2}$$

$$y = at(3-t^2) \tag{3}$$

or

$$x = 3a(t^2-3) \tag{4}$$



$$y = at(t^2-3). \tag{5}$$

The curve is also known as CATALAN'S TRISECTRIX and L'HOSPITAL'S CUBIC. The name Tschirnhaus's cubic is given in R. C. Archibald's 1900 paper attempting to classify curves (MacTutor Archive). Tschirnhaus's cubic is the NEGATIVE PEDAL CURVE of a PARABOLA with respect to the FOCUS.

Tschirnhausen Cubic Pedal Curve

The PEDAL CURVE to the TSCHIRNHAUSEN CUBIC for PEDAL POINT at the origin is the PARABOLA

$$x = 1 - t^2$$

$$y = 2t.$$

See also PARABOLA, PEDAL CURVE, PEDAL POINT, TSCHIRNHAUSEN CUBIC

Tschirnhausen Transformation

A transformation of a POLYNOMIAL equation $f(x) = 0$ which is OF THE FORM $y = g(x)/h(x)$ where g and h are POLYNOMIALS and $h(x)$ does not vanish at a root of $f(x) = 0$. The CUBIC EQUATION is a special case of such a transformation. Tschirnhaus (1683) showed that a POLYNOMIAL of degree $n > 2$ can be reduced to a form in which the x^{n-1} and x^{n-2} terms have 0 COEFFICIENTS. In 1786, E. S. Bring showed that a general QUINTIC EQUATION can be reduced to the form

$$x^5 + px + q = 0.$$

In 1834, G. B. Jerrard showed that a Tschirnhaus transformation can be used to eliminate the x^{n-1}, x^{n-2}, *and* x^{n-3} terms for a general POLYNOMIAL equation of degree $n > 3$.

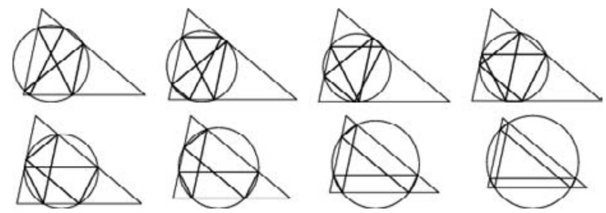
Tubular Neighborhood



This entry contributed by RYAN BUDNEY

A tubular neighborhood of a SUBMANIFOLD $N \in M$ is an embedding of the NORMAL BUNDLE (ν_N) of N into M, i.e., $f : \nu_N \to M$, where the image of the ZERO SECTION of the NORMAL BUNDLE is equal to $N \in M$.

See also BALL, EMBEDDING, KNOT EXTERIOR, PRODUCT NEIGHBORHOOD

Tucker Circles

The Tucker circles are a generalization of the COSINE CIRCLE and LEMOINE CIRCLE which can be viewed as a family of circles obtained by parallel displacing sides of the corresponding COSINE or LEMOINE HEXAGON. No matter how the segments are displaced, the TUCKER HEXAGON will close, and the 12 vertices will be CONCYCLIC. The COSINE CIRCLE and LEMOINE CIRCLE correspond to the special case where three sides of the TUCKER HEXAGON concur.

Let three equal lines P_1Q_1, P_2Q_2, and P_3Q_3 be drawn ANTIPARALLEL to the sides of a triangle so that two (say P_2Q_2 and P_3Q_3) are on the same side of the third line as $A_2P_2Q_3A_3$. Then $P_2Q_3P_3Q_2$ is an isosceles TRAPEZOID, i.e., P_3Q_2, P_1Q_3, and P_2Q_1 are parallel to the respective sides. The MIDPOINTS C_1, C_2, and C_3 of the antiparallels are on the respective symmedians and divide them proportionally. If T divides KO in the same ratio, TC_1, TC_2, TC_3 are parallel to the radii OA_1, OA_2, and OA_3 and equal. Since the antiparallels are perpendicular to the symmedians, they form equal chords of a circle, called a Tucker circle, which passes through the six given points and has center T on the line KO (Honsberger 1995, pp. 92–94).

If

$$c \equiv \frac{\overline{KC_1}}{\overline{KA_1}} = \frac{\overline{KC_2}}{\overline{KA_2}} = \frac{\overline{KC_3}}{\overline{KA_3}} = \frac{\overline{KT}}{\overline{KO}},$$

then the radius of the Tucker circle is

$$R\sqrt{c^2 + (1-c)^2 \tan \omega},$$

where ω is the BROCARD ANGLE.

The COSINE CIRCLE, LEMOINE CIRCLE, and TAYLOR CIRCLE are Tucker circles.

Turán Graph

The (n, k)-Turán graph is the EXTREMAL GRAPH on n VERTICES which contains no k-CLIQUE. In other words, the Turán graph has the maximum possible number of EDGES of any n-vertex graph not containing a COMPLETE GRAPH K_k. TURÁN'S THEOREM gives the maximum number of edges $t(n, k)$ for the (n, k)-Turán graph. For $k=3$,

$$t(n,\ 3) = \tfrac{1}{4}n^2,$$

so the Turán graph is given by the COMPLETE BIPARTITE GRAPHS

$$\begin{cases} K_{n/2,\ n/2} & n \text{ even} \\ K_{(n-1)/2,(n+1)/2} & n \text{ odd.} \end{cases}$$

Turán graphs cen be generated using `Turan[n, p]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

Turán's Theorem

Let $G(V, E)$ be a GRAPH with VERTICES V and EDGES E on n VERTICES without a k-CLIQUE. Then

$$t(n, k) \leq \frac{(k-2)n^2}{2(k-1)},$$

where $t(n, k) = |E|$ is the EDGE NUMBER. More precisely, the K-GRAPH $K_{n_1, \ldots, n_{k-1}}$ with $|n_i - n_j| \leq 1$ for $i \neq j$ is the unique GRAPH without a k-CLIQUE with the maximal number of EDGES $t(n, k)$.

Turbine

A VECTOR FIELD on a CIRCLE in which the directions of the VECTORS are all at the same ANGLE to the CIRCLE.

See also CIRCLE, VECTOR FIELD

Turing Machine

A theoretical computing machine which consists of an infinitely long magnetic tape on which instructions can be written and erased, a finite register of memory, and a processor capable of carrying out the following instructions: move the tape right, move the tape left, change the state of the register based on its current value and a value on the tape, and write or erase a value on the tape. The machine keeps processing instructions until it reaches a particular state, causing it to halt. Determining whether a Turing machine will halt for a given input and set of rules is called the HALTING PROBLEM.

Tutte's Theorem

Let G be a GRAPH and S a SUBGRAPH of G. Let the number of ODD components in $G-S$ be denoted S', and $|S|$ the number of VERTICES of S. The condition $|S| \geq S'$ for every SUBSET of VERTICES is NECESSARY and SUFFICIENT for G to have a 1-FACTOR.

Twin Peaks

For an INTEGER $n \geq 2$, let $\operatorname{lpf}(x)$ denote the LEAST PRIME FACTOR of n. A PAIR of INTEGERS (x, y) is called a twin peak if

1. $x < y$,
2. $\operatorname{lpf}(x) = \operatorname{lpf}(y)$,
3. For all z, $x < z < y$ IMPLIES $\operatorname{lpf}(z) < \operatorname{lpf}(x)$.

A broken-line graph of the least prime factor function resembles a jagged terrain of mountains. In terms of this terrain, a twin peak consists of two mountains of equal height with no mountain of equal or greater height between them. Denote the height of twin peak (x, y) by $p = \operatorname{lpf}(x) = \operatorname{lpf}(y)$. By definition of the LEAST PRIME FACTOR function, p must be PRIME.

Call the distance between two twin peaks (x, y)

$$s \equiv y - x.$$

Then s must be an EVEN multiple of p; that is, $s = kp$ where k is EVEN. A twin peak with $s = kp$ is called a kp-twin peak. Thus we can speak of $2p$-twin peaks, $4p$-twin peaks, etc. A kp-twin peak is fully specified by k, p, and x, from which we can easily compute $y \equiv x + kp$.

The set of kp-twin peaks is periodic with period $q = p\#$, where $p\#$ is the PRIMORIAL of p. That is, if (x, y) is a kp-twin peak, then so is $(x+q, y+q)$. A fundamental kp-twin peak is a twin peak having x in the fundamental period $[0, q)$. The set of fundamental kp-twin peaks is symmetric with respect to the fundamental period; that is, if (x, y) is a twin peak on $[0, q)$, then so is $(q-y, q-x)$.

The question of the EXISTENCE of twin peaks was first raised by David Wilson in the math-fun mailing list on Feb. 10, 1997. Wilson already had privately showed the EXISTENCE of twin peaks of height $p \leq 13$ to be unlikely, but was unable to rule them out altogether. Later that same day, John H. Conway, Johan de Jong, Derek Smith, and Manjul Bhargava collaborated to discover the first twin peak. Two hours at the blackboard revealed that $p = 113$ admits the $2p$-twin peak

$$x = 126972592296404970720882679404584182254788131$$

which settled the EXISTENCE question. Immediately thereafter, Fred Helenius found the smaller $2p$-twin

peak with $p = 89$ and

$$x = 95038449267493909904548548436 25839.$$

The effort now shifted to finding the least PRIME p admitting a $2p$-twin peak. On Feb. 12, 1997, Fred Helenius found $p = 71$, which admits 240 fundamental $2p$-twin peaks, the least being

$$x = 7310131732015251470110369.$$

Helenius's results were confirmed by Dan Hoey, who also computed the least $2p$-twin peak $L(2p)$ and number of fundamental $2p$-twin peaks $N(2p)$ for $p = 73$, 79, and 83. His results are summarized in the following table (Sloane's A009190).

p	$L(2p)$	$N(2p)$
71	7310131732015251470110369	240
73	2061519317176132799110061	40296
79	3756800873017263196139951	164440
83	6316254452384500173544921	6625240

The $2p$-twin peak of height $p = 73$ is the smallest known twin peak. Wilson found the smallest known $4p$-twin peak with $p = 1327$, as well as another very large $4p$-twin peak with $p = 3203$. Richard Schroeppel noted that the latter twin peak is at the high end of its fundamental period and that its reflection within the fundamental period $[0, p\#)$ is smaller.

Many open questions remain concerning twin peaks, e.g.,

1. What is the smallest twin peak (smallest n)?
2. What is the least PRIME p admitting a $4p$-twin peak?
3. Do $6p$-twin peaks exist?
4. Is there, as Conway has argued, an upper bound on the span of twin peaks?
5. Let $p < q < r$ be PRIME. If p and r each admit kp-twin peaks, does q then necessarily admit a kp-twin peak?

Twin Prime Conjecture

There are two related conjectures, each called the twin prime conjecture. The first version states that there are an infinite number of pairs of TWIN PRIMES (Guy 1994, p. 19). It is not known if there are an infinite number of such PRIMES (Wells 1986, p. 41; Shanks 1993, p. 30), but it seems almost certain to be true (Hardy and Wright 1979, p. 5). In the words of Shanks (1993, p. 219), "the evidence is overwhelming."

The conjecture that there are infinitely many integers n such that $n+1$ is prime and n is twice a prime is very closely related (Shanks 1993, p. 30).

A second twin prime conjecture states that adding a correction proportional to $1/\ln p$ to a computation of BRUN'S CONSTANT ending with $\ldots + 1/p + 1/(p+2)$ will give an estimate with error less than $c(\sqrt{p}\ln p)^{-1}$. An extended form of this conjecture, sometimes called the strong twin prime conjecture (Shanks 1993, p. 30) states that

$$P_x(p,\ p+2) \sim 2\,\Pi_2 \int_2^x \frac{dx}{(\ln x)^2},$$

where Π_2 is the TWIN PRIMES CONSTANT (Hardy and Littlewood 1922). This conjecture is a special case of the more general PRIME PATTERNS CONJECTURE corresponding to the set $S = \{0,\ 2\}$.

Twin Primes

Twin primes are pairs of PRIMES OF THE FORM $(p, p+2)$. The term "twin prime" was coined by Paul Stäckel (1892–1919; Tietze 1965, p. 19). The first few twin primes are $n \pm 1$ for $n = 4$, 6, 12, 18, 30, 42, 60, 72, 102, 108, 138, 150, 180, 192, 198, 228, 240, 270, 282, ... (Sloane's A014574). Explicitly, these are (3, 5), (5, 7), (11, 13), (17, 19), (29, 31), (41, 43), ... (Sloane's A001359 and A006512).

The following table gives the first few p for the twin primes $(p,\ p+2)$, COUSIN PRIMES $(p,\ p+4)$, SEXY PRIMES $(p, p+6)$, etc.

Triplet	Sloane	First Member
$(p, p+2)$	Sloane's A001359	3, 5, 11, 17, 29, 41, 59, 71, ...

$(p, p+4)$	Sloane's A023200	3, 7, 13, 19, 37, 43, 67, 79, ...
$(p, p+6)$	Sloane's A023201	5, 7, 11, 13, 17, 23, 31, 37, ...
$(p, p+8)$	Sloane's A023202	3, 5, 11, 23, 29, 53, 59, 71, ...
$(p, p+10)$	Sloane's A023203	3, 7, 13, 19, 31, 37, 43, 61, ...
$(p, p+12)$	Sloane's A046133	5, 7, 11, 17, 19, 29, 31, 41, ...

Let $\pi_2(n)$ be the number of twin primes p and $p+2$ such that $p \leq n$. It is not known if there are an infinite number of such PRIMES (Wells 1986, p. 41; Shanks 1993), but it seems almost certain to be true (Hardy and Wright 1979, p. 5). All twin primes except (3, 5) are OF THE FORM $6n \pm 1$. J. R. Chen has shown there exists an INFINITE number of PRIMES p such that $p+2$ has at most two factors (Le Lionnais 1983, p. 49). Bruns proved that there exists a computable INTEGER x_0 such that if $x \geq x_0$, then

$$\pi_2(x) < \frac{100x}{(\ln x)^2} \tag{1}$$

(Ribenboim 1996, p. 261). It has been shown that

$$\pi_2(x) \leq c \prod_{p>2} \left[1 - \frac{1}{(p-1)^2}\right] \frac{x}{(\ln x)^2} \times \left[1 + \mathcal{O}\left(\frac{\ln \ln x}{\ln x}\right)\right], \tag{2}$$

written more concisely as

$$\pi_2(x) \leq c\, \Pi_2 \frac{x}{(\ln x)^2} \left[1 + \mathcal{O}\left(\frac{\ln \ln x}{\ln x}\right)\right], \tag{3}$$

where Π_2 is known as the TWIN PRIMES CONSTANT and c is another constant. The constant c has been reduced to $68/9 \approx 7.5556$ (Fouvry and Iwaniec 1983), $128/17 \approx 7.5294$ (Fouvry 1984), 7 (Bombieri *et al.* 1986), 6.9075 (Fouvry and Grupp 1986), and 6.8354 (Wu 1990). The bound on c is further reduced to 6.8325 (Haugland 1999). This calculation involved evaluation of 7-fold integrals and fitting of three different parameters. Hardy and Littlewood conjectured that $c = 2$ (Ribenboim 1996, p. 262).

Wolf notes that the formula

$$\pi_2(x) \sim \Pi_2 \frac{[\pi(x)]^2}{x}, \tag{4}$$

which increases as $\Pi_2 x/(\ln x)^2$ for large x, agrees with numerical data much better than does $\Pi_2 x/(\ln x)^2$, although not as well as $\Pi_2 \operatorname{Li}_2(x)$.

Extending the search done by Brent in 1974 or 1975, Wolf has searched for the analog of the SKEWES NUMBER for twins, i.e., an x such that $\pi_2(x) - \Pi_2 \operatorname{Li}_2(x)$ changes sign. Wolf checked numbers up to 2^{42} and found more than 90,000 sign changes. From this data, Wolf conjectured that the number of sign changes $\nu(n)$ for $x < n$ of $\pi_2(x) - \Pi_2 \operatorname{Li}_2(x)$ is given by

$$\nu(n) \sim \frac{\sqrt{n}}{\ln n}. \tag{5}$$

Proof of this conjecture would also imply the existence an infinite number of twin primes.

Define

$$E \equiv \liminf_{n\to\infty} \frac{p_{n+1} - p_n}{\ln p_n}. \tag{6}$$

If there are an infinite number of twin primes, then $E = 0$. The best upper limit to date is $E \leq \frac{1}{4} + \pi/16 = 0.44634\ldots$ (Huxley 1973, 1977). The best previous values were 15/16 (Ricci), $(2+\sqrt{3})/8 = 0.46650\ldots$ (Bombieri and Davenport 1966), and $(2\sqrt{2}-1)/4 = 0.45706\ldots$ (Pil'Tai 1972), as quoted in Le Lionnais (1983, p. 26).

Some large twin primes are $10,006,428 \pm 1$, $1,706,595 \times 2^{11235} \pm 1$, and $571,305 \times 2^{7701} \pm 1$. An up-to-date table of known twin primes with 2000 or more digits follows. An extensive list is maintained by C. Caldwell at http://www.utm.edu/cgi-bin/caldwell/primes.cgi/twin.

$(p, p+1)$	Digits	Reference
$260,497,545 \times 2^{6625} \pm 1$	2003	Atkin and Rickert 1984
$43,690,485,351,513 \times 10^{1995} \pm 1$	2009	Dubner, Atkin 1985
$2,846!!!! \pm 1$	2151	Dubner 1992
$10,757,0463 \times 10^{2250} \pm 1$	2259	Dubner, Atkin 1985
$663,777 \times 2^{7650} \pm 1$	2309	Brown *et al.* 1989
$75,188,117,004 \times 10^{2298} \pm 1$	2309	Dubner 1989
$571305 \times 2^{7701} \pm 1$	2324	Brown *et al.* 1989
$1,171,452,282 \times 10^{2490} \pm 1$	2500	Dubner 1991
$459 \cdot 2^{8529} \pm 1$	2571	Dubner 1993
$1,706,595 \cdot 2^{11235} \pm 1$	3389	Noll *et al.* 1989
$4,655,478,828 \cdot 10^{3429} \pm 1$	3439	Dubner 1993
$1,692,923,232 \cdot 10^{4020} \pm 1$	4030	Dubner 1993
$6,797,727 \cdot 2^{15328} \pm 1$	4622	Forbes 1995

$697,053,813 \cdot 2^{16352} \pm 1$	4932	Indlekofer and Ja'rai 1994
$570,918,348 \cdot 10^{5120} \pm 1$	5129	Dubner 1995
$242,206,083 \cdot 2^{38880} \pm 1$	11713	Indlekofer and Ja'rai 1995

The last of these is the largest known twin prime pair. In 1995, Nicely discovered a flaw in the Intel ® Pentium™ microprocessor by computing the reciprocals of 824,633,702,441 and 824,633,702,443, which should have been accurate to 19 decimal places but were incorrect from the tenth decimal place on (Cipra 1995, 1996; Nicely 1996).

If $n \geq 2$, the INTEGERS n and $n+2$ form a pair of twin primes IFF

$$4[(n-1)!+1]+n \equiv 0 \pmod{n(n+2)}. \tag{7}$$

$n = pp'$ where $(p,\ p')$ is a pair of twin primes IFF

$$\phi(n)\sigma(n) = (n-3)(n+1) \tag{8}$$

(Ribenboim 1996, p. 259). S. M. Ruiz has found the unexpected result that $(n,\ n+2)$ are twin primes IFF

$$\sum_{i=1}^{n} i^a \left(\left\lfloor \frac{n+2}{i} \right\rfloor + \left\lfloor \frac{n}{i} \right\rfloor \right) = 2 + n^a + \sum_{i=1}^{n} i^a \left(\left\lfloor \frac{n+1}{i} \right\rfloor + \left\lfloor \frac{n-1}{i} \right\rfloor \right) \tag{9}$$

for $a \geq 0$, where $\lfloor x \rfloor$ is the FLOOR FUNCTION.

The values of $\pi_2(n)$ were found by Brent (1976) up to $n = 10^{11}$. T. Nicely calculated them up to 10^{14} in his calculation of BRUN'S CONSTANT. The following table gives the number less than increasing powers of 10 (Sloane's A007508; Nicely 1998, 1999). Using a distributed computation, Fry *et al.* obtained $\pi_2(10^{16})$ in 2000, although this value has not yet been made public. The following table gives $\pi(10^n)$ for various values of n, and extends a similar table with early references given by Ribenboim (1996, p. 263).

n	$\pi_2(n)$
10^3	35
10^4	205
10^5	1224
10^6	8,169
10^7	58,980
10^8	440,312
10^9	3,424,506
10^{10}	27,412,679
10^{11}	224,376,048
10^{12}	1,870,585,220
10^{13}	15,834,664,872
10^{14}	135,780,321,665
10^{15}	1,177,209,242,304

It is conjectured that every even number is a sum of a pair of twin primes except a finite number of exceptions whose first few terms are 2, 4, 94, 96, 98, 400, 402, 404, 514, 516, 518, ... (Sloane's A007534; Wells 1986, p. 132).

Twin Primes Constant

The twin primes constant Π_2 (sometimes also denoted C_2) is defined by

$$\Pi_2 \equiv \prod_{\substack{p>2 \\ p\ \text{prime}}} \left[1-\frac{1}{(p-1)^2}\right] \tag{1}$$

$$\ln\left(\tfrac{1}{2}\Pi_2\right) = \sum_{\substack{p\geq 3 \\ p\ \text{prime}}} \ln\left[\frac{p(p-2)}{(p-1)^2}\right]$$

$$= \sum_{\substack{p\geq 3 \\ p\ \text{prime}}} \left[\ln\left(1-\frac{2}{p}\right)-2\ln\left(1-\frac{1}{p}\right)\right]$$

$$= -\sum_{j=2}^{\infty} \frac{2^j-2}{j} \sum_{\substack{p\geq 3 \\ p\ \text{prime}}} p^{-j}, \tag{2}$$

where the ps in sums and products are taken over PRIMES only. Flajolet and Vardi (1996) give series with accelerated convergence

$$\Pi_2 = \prod_{n=2}^{\infty} [\zeta(n)(1-2^{-n})]^{-I_n} \tag{3}$$

$$= \tfrac{3}{4}\tfrac{15}{16}\tfrac{35}{36} \prod_{n=2}^{\infty} [\zeta(n)(1-2^{-n})(1-3^{-n}) \times (1-5^{-n})(1-7^{-n})]^{-I_n}, \tag{4}$$

with

$$I_n \equiv \frac{1}{n} \sum_{d|n} \mu(d) 2^{n/d}, \tag{5}$$

where $\mu(x)$ is the MÖBIUS FUNCTION. (4) has convergence like $\sim (11/2)^{-n}$.

Π_2 was computed to 45 digits by Wrench (1961) and Gourdon and Sebah list 60 digits.

$$\Pi_2 = 0.6601618158\ldots. \tag{6}$$

Le Lionnais (1983, p. 30) calls Π_2 the SHAH-WILSON CONSTANT, and $2\Pi_2$ the twin prime constant (Le Lionnais 1983, p. 37).

Twirl

A ROTATION combined with an EXPANSION or CONTRACTION.

See also SCREW, SHIFT

Twist

The twist of a ribbon measures how much it twists around its axis and is defined as the integral of the incremental twist around the ribbon. A formula for the twist is given by

$$\mathrm{Tw}(K) = \frac{1}{2\pi} \int_K ds\ \varepsilon_{\mu\nu\alpha} \frac{dx^\mu}{ds}\ n^\nu \frac{dn^\alpha}{ds}, \qquad (1)$$

where K is parameterized by $x^\mu(s)$ for $0 \le s \le L$ along the length of the knot by parameter s, and the FRAME K_f associated with K is

$$y^\mu = x^\mu(s) + \varepsilon n^\mu(s), \qquad (2)$$

where ε is a small parameter and $n^\mu(s)$ is a unit VECTOR FIELD normal to the curve at s (Kaul 1999).

Letting Lk be the linking number of the two components of a ribbon, Tw be the twist, and Wr be the WRITHE, then the CALUGAREANU THEOREM states that

$$\mathrm{Lk}(R) = \mathrm{Tw}(R) + \mathrm{Wr}(R) \qquad (3)$$

(Adams 1994, p. 187).

Twistor Correspondence

This entry contributed by EDGAR VAN TUYLL

Oriented spheres in complex Euclidean 3-space can be represented as lines in complex projective 3-space ("Lie correspondence"), and the spheres may be thought of as the $t = 0$ representation of the light cones of events in MINKOWSKI SPACE. In effect, the Lie correspondence represents the points of (complexified compactified) MINKOWSKI SPACE by lines in complex projective 3-space, where meeting lines describe null-separated Minkowski points. This is the twistor correspondence.

Tychonof Compactness Theorem

The topological product of any number of COMPACT SPACES is COMPACT.

Type

Whitehead and Russell (1927) devised a hierarchy of "types" in order to eliminate self-referential statements from *Principia Mathematica*, which purported to derive all of mathematics from logic. A set of the lowest type contained only objects (not sets), a set of the next higher type could contain only objects or sets of the lower type, and so on. Unfortunately, GÖDEL'S INCOMPLETENESS THEOREM showed that both *Principia Mathematica* and all consistent formal systems must be incomplete.

See also CLASS (SET), GÖDEL'S INCOMPLETENESS THEOREM

U

U(n) Basic Hypergeometric Series

Multiple series generalizations of basic hypergeometric series over the UNITARY GROUPS $U(n+1)$. The fundamental theorem of $U(n)$ series takes $c_1, \ldots, c_n$ and $x_1, \ldots, x_n$ as indeterminates and $n \geq 1$. Then

$$\frac{(c_1 \cdots c_n;\ q)N}{(q;\ q)N}$$

$$= \sum_{\substack{y_1, y_2, \ldots, y_n \geq 0 \\ |\mathbf{y}|=N}} \left\{ \prod_{1 \leq r < s \leq n} \left[\frac{1 - \frac{x_r}{x_s} q^{y_r - y_s}}{1 - \frac{x_r}{x_s}} \right] \right.$$

$$\left. \times \prod_{r,\ s=1}^{n} \left[\frac{\left(\frac{x_r}{x_s} c_s;\ q \right)_{yr}}{\left(q \frac{x_r}{x_s};\ q \right)_{yr}} \right] \left[q^{y_2 + 2y_3 + \ldots + (n-1)y_n} \right] \right\},$$

where it is assumed that none of the denominators vanish (Bhatnagar 1995, p. 22). The series in this theorem is called an $SU(n)$ series (Milne 1985; Bhatnagar 1995, p. 22).

Many other q-results, including the Q-BINOMIAL THEOREM and Q-SAALSCHÜTZ SUM, can be generalized to $U(n+1)$ series.

Ulam Number

ULAM SEQUENCE

Ulam Sequence

The Ulam sequence $\{a_i\} = (u,\ v)$ is defined by $a_1 = u$, $a_2 = v$, with the general term a_n for $n > 2$ given by the least INTEGER expressible uniquely as the SUM of two distinct earlier terms. The numbers so produced are sometimes called U-NUMBERS or ULAM NUMBERS.

The first few numbers in the (1, 2)-Ulam sequence are 1, 2, 3, 4, 6, 8, 11, 13, 16, ... (Sloane's A002858). Here, the first term after the initial (1, 2) is obviously 3 since $3 = 1 + 2$. The next term is $4 = 1 + 3$. (We don't have to worry about $4 = 2 + 2$ since it is a sum of a single term instead of *distinct* terms.) 5 is not a member of the sequence since it is representable in *two* ways, $5 = 1 + 4 = 2 + 3$, but $6 = 2 + 4$ is a member.

Proceeding in the manner, we can generate Ulam sequences for any $(u,\ v)$, examples of which are given in the table below.

(u, v)	Sloane	Sequence
(1, 2)	Sloane's A002858	1, 2, 3, 4, 6, 8, 11, 13, 16, 18, ...
(1, 3)	Sloane's A002859	1, 3, 4, 5, 6, 8, 10, 12, 17, 21, ...
(1, 4)	Sloane's A003666	1, 4, 5, 6, 7, 8, 10, 16, 18, 19, ...
(1, 5)	Sloane's A003667	1, 5, 6, 7, 8, 9, 10, 12, 20, 22, ...
(2, 3)	Sloane's A001857	2, 3, 5, 7, 8, 9, 13, 14, 18, 19, ...
(2, 4)	Sloane's A048951	2, 4, 6, 8, 12, 16, 22, 26, 32, 36, ...
(2, 5)	Sloane's A007300	2, 5, 7, 9, 11, 12, 13, 15, 19, 23, ...

Schmerl and Spiegel (1994) proved that Ulam sequences $(2, v)$ for ODD $v \geq 5$ have exactly two EVEN terms. Ulam sequences with only finitely many EVEN terms eventually must have periodic successive differences (Finch 1991, 1992abc). Cassaigne and Finch (1995) proved that the Ulam sequences $(4, v)$ for $5 \leq v \equiv 1 \pmod 4$ have exactly three EVEN terms.

The Ulam sequence can be generalized by the s-ADDITIVE SEQUENCE.

See also GREEDY ALGORITHM, s-ADDITIVE SEQUENCE, STÖHR SEQUENCE

Ultrafilter

This entry contributed by VIKTOR BENGTSSON

Let S be a nonempty set, then an ultrafilter on S is a nonempty collection F of subsets of S having the following properties:

1. $\emptyset \notin F$.
2. If $A, B \in F$ then $A \cap B \in F$.
3. If $A \in F$ and $A \subseteq B \subseteq S$ then $B \in F$.
4. For any subset A of S, either $A \in F$ or its complement $A' = S - A \in F$.

An ultrafilter F on S is said to be free if it contains the COFINITE FILTER F_S of S.

See also COFINITE FILTER, FILTER

Ultrametric

An ultrametric is a METRIC which satisfies the following strengthened version of the TRIANGLE INEQUALITY,

$$d(x, z) \leq \max(d(x, y), d(y, z))$$

for all x, y, z. At least two of $d(x, y)$, $d(y, z)$, and $d(x, z)$ are the same.

Let X be a SET, and let $X^{\mathbb{N}}$ (where N is the SET of NATURAL NUMBERS) denote the collection of sequences of elements of X (i.e., all the possible sequences x_1, x_2, x_3, ...). For sequences $a=(a_1, a_2, \ldots)$, $b=(b_1, b_2, \ldots)$, let n be the number of initial places where the sequences agree, i.e., $a_1=b_1$, $a_2=b_2$, ..., $a_n=b_n$, but $a_{n+1}\neq b_{n+1}$. Take $n=0$ if $a_1\neq b_1$. Then defining $d(a, b)=2^{-n}$ gives an ultrametric.

The p-ADIC NORM metric is another example of an ultrametric.

See also METRIC, p-ADIC NUMBER

Ultrapower

This entry contributed by MATT INSALL

A specific type of ULTRAPRODUCT that can be used to construct nonstandard universes and obtain the TRANSFER PRINCIPLE as a corollary of LOS' THEOREM for ultraproducts.

Umbilic Point

A point on a surface at which the CURVATURE is the same in any direction.

Umbral Algebra

The algebra structure of linear functionals on polynomials of a single variable (Roman 1984, pp. 2–).

See also UMBRAL CALCULUS

References

Roman, S. "The Umbral Algebra." §2.1 in *The Umbral Calculus.* New York: Academic Press, pp. 6–2, 1984.

Umbral Calculus

Roman (1984, p. 2) describes umbral calculus as the study of the class of SHEFFER SEQUENCES. Umbral calculus provides a formalism for the systematic derivation and classification of almost all classical combinatorial identities for polynomial sequences, along with associated GENERATING FUNCTIONS, expansions, duplication formulas, RECURRENCE RELATIONS, inversions, RODRIGUES FORMULA, etc., (e.g., the EULER-MACLAURIN INTEGRATION FORMULAS, Boole's summation formula, the CHU-VANDERMONDE IDENTITY, NEWTON'S DIVIDED DIFFERENCE INTERPOLATION FORMULA, GREGORY'S FORMULA, LAGRANGE INVERSION).

The term "umbral calculus" was coined by Sylvester from the word "umbra" (meaning "shadow" in Latin), and reflects the fact that for many types of identities involving sequences of polynomials with POWERS a^n, "shadow" identities are obtained when the polynomials are changed to discrete values and the exponent in a^n is changed to the FALLING FACTORIAL $(a)_n\equiv a(a-1)\cdots(a-n+1)$.

For example, NEWTON'S FORWARD DIFFERENCE FORMULA written in the form

$$f(x+a)=\sum_{n=0}^{\infty}\frac{(a)_n\Delta^n f(x)}{n!} \tag{1}$$

with $f(x+a)\equiv f_{x+a}$ looks suspiciously like a finite analog of the TAYLOR SERIES expansion

$$f(x+a)=\sum_{n=0}^{\infty}\frac{a^n\tilde{D}^n f(x)}{n!}, \tag{2}$$

where $\tilde{D}$ is the DIFFERENTIAL OPERATOR. Similarly, the CHU-VANDERMONDE IDENTITY

$$(x+a)_n=\sum_{k=0}^{\infty}\binom{n}{k}(a)_k(x)_{n-k} \tag{3}$$

with $\binom{n}{k}$ a BINOMIAL COEFFICIENT, looks suspiciously like an analog of the BINOMIAL THEOREM

$$(x+a)^n=\sum_{k=0}^{\infty}\binom{n}{k}a^k x^{n-k} \tag{4}$$

(Di Bucchianico and Loeb).

Uncia

$$1 \text{ uncia} \equiv \tfrac{1}{12}.$$

The word *uncia* was Latin for a unit equal to 1/12 of another unit called the *as*. The words "inch" (1/12 of a foot) and "ounce" (originally 1/12 of a pound and still 1/12 of a "Troy pound," now used primarily to weigh precious metals) are derived from the word *uncia*.

Uncorrelated

Variables x_i and x_j are said to be uncorrelated if their COVARIANCE is zero:

$$\operatorname{cov}(x_i,\ x_j) = 0.$$

INDEPENDENT STATISTICS are always uncorrelated, but the converse is not necessarily true.

See also COVARIANCE, INDEPENDENT STATISTICS, UNCORRELATED NUMBERS

Uncorrelated Numbers

A sequence of numbers α_n is said to be uncorrelated if it satisfies

$$\lim_{n\to\infty} \frac{1}{2n} \sum_{m=-n}^{n} \alpha_m^2 = 1$$

$$\lim_{n\to\infty} \frac{1}{2n} \sum_{m=-n}^{n} \alpha_m \alpha_{k+m} = 0$$

for $k \neq 0$.

Undecagon

HENDECAGON

Undecidable

Not DECIDABLE as a result of being neither formally provable nor unprovable.

See also GÖDEL'S INCOMPLETENESS THEOREM, RICHARDSON'S THEOREM

Undecillion

In the American system, 10^{36}.

See also LARGE NUMBER

Undefined

An expression in mathematics which does not have meaning and so which is not assigned an interpretation. For example, DIVISION BY ZERO is undefined in the FIELD of REAL NUMBERS.

See also AMBIGUOUS, DIVISION BY ZERO, ILL DEFINED, INDETERMINATE, WELL DEFINED

Underbar

UNDERSCORE

Underbrace

BRACE

Underdamping

DAMPED SIMPLE HARMONIC MOTION–UNDERDAMPING

Underdot

A dot placed under a symbol to indicate a DUMMY VARIABLE, e.g., $\underset{\cdot}{c}_1$ (Comtet 1974, p. 32). This notation, however, is not very common.

See also DUMMY VARIABLE

References

Comtet, L. *Advanced Combinatorics: The Art of Finite and Infinite Expansions, rev. enl. ed.* Dordrecht, Netherlands: Reidel, p. 32, 1974.

Underlying Space

The space $|K|$ which is the subset of $\mathbb{R}^n$ that is the union of the simplices in a SIMPLICIAL COMPLEX K. The term POLYTOPE is sometimes used as a synonym for underlying space (Munkres 1991, p. 8).

See also POLYHEDRON, POLYTOPE

References

Munkres, J. R. *Analysis on Manifolds.* Reading, MA: Addison-Wesley, 1991.

Underscore

A horizontal line placed under a symbol to indicate some special property. Underscores are sometimes used instead of over-arrows or bold typeface to indicate a VECTOR, for example $\mathbf{x} = \underline{x}$.

References

Bringhurst, R. *The Elements of Typographic Style, 2nd ed.* Point Roberts, WA: Hartley and Marks, p. 286, 1997.

Undetermined Coefficients Method

Given a nonhomogeneous ORDINARY DIFFERENTIAL EQUATION, select a differential operator which will annihilate the right side, and apply it to both sides. Find the solution to the homogeneous equation, plug it into the left side of the original equation, and solve for constants by setting it equal to the right side. The solution is then obtained by plugging the determined constants into the homogeneous equation.

See also ORDINARY DIFFERENTIAL EQUATION

Undirected Graph

A GRAPH for which the relations between pairs of vertices are symmetric, so that each edge has no directional character (as opposed to a DIRECTED GRAPH). Unless otherwise indicated by context, the term "graph" can usually be taken to mean "undirected graph."

See also DEGREE SEQUENCE, DIRECTED GRAPH, GRAPH

References

Skiena, S. "Undirected Graphs." §3.2.4 in *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, pp. 92–3, 1990.

Undulating Number

A number OF THE FORM $aba\cdots$, $abab\cdots$, etc. The first few nontrivial undulants (with the stipulation that $a \neq b$) are 101, 121, 131, 141, 151, 161, 171, 181, 191, 202, 212, ... (Sloane's A046075). Including the trivial 1- and 2-digit undulants and dropping the requirement that $a \neq b$ gives Sloane's A033619.

The first few undulating SQUARES are 121, 484, 676, 69696, ... (Sloane's A016073), with no larger such numbers of fewer than a million digits (Pickover 1995). Several tricks can be used to speed the search for square undulating numbers, especially by examining the possible patterns of ending digits. For example, the only possible sets of four trailing digits for undulating SQUARES are 0404, 1616, 2121, 2929, 3636, 6161, 6464, 6969, 8484, and 9696.

The only undulating POWER $n^p = aba\cdots$ for $3 \leq p \leq 31$ and up to 100 digits is $7^3 = 343$ (Pickover 1995). A large undulating prime is given by $7 + 720(100^{49} - 1)/99$ (Pickover 1995).

A binary undulant is a POWER of 2 whose base-10 representation contains one or both of the sequences $010\cdots$ and $101\cdots$. The first few are 2^n for $n = 103$, 107, 138, 159, 179, 187, 192, 199, 205, ... (Sloane's A046076). The smallest n for which an undulating sequence of *exactly* d-digit occurs for $d = 3$, 4, ... are $n = 103,138,875,949,6617,1802,14545,$ ... (Sloane's A046077). An undulating binary sequence of length 10 occurs for $n = 1,748,219$ (Pickover 1995).

Unduloid

A SURFACE OF REVOLUTION with constant NONZERO MEAN CURVATURE also called an ONDULOID. It is a ROULETTE obtained from the path described by the FOCI of a CONIC SECTION when rolled on a LINE. This curve then generates an unduloid when revolved about the LINE. These curves are special cases of the shapes assumed by soap film spanning the gap between prescribed boundaries. The unduloid of a PARABOLA gives a CATENOID.

Unexpected Hanging Paradox

A PARADOX also known as the SURPRISE EXAMINATION PARADOX or PREDICTION PARADOX.

A prisoner is told that he will be hanged on some day between Monday and Friday, but that he will not know on which day the hanging will occur before it happens. He cannot be hanged on Friday, because if he were still alive on Thursday, he would know that the hanging will occur on Friday, but he has been told he will not know the day of his hanging in advance. He cannot be hanged Thursday for the same reason, and the same argument shows that he cannot be hanged on any other day. Nevertheless, the executioner unexpectedly arrives on some day other than Friday, surprising the prisoner.

This PARADOX is similar to that in Robert Louis Stevenson's "BOTTLE IMP PARADOX," in which you are offered the opportunity to buy, for whatever price you wish, a bottle containing a genie who will fulfill your every desire. The only catch is that the bottle must thereafter be resold for a price smaller than what you paid for it, or you will be condemned to live out the rest of your days in excruciating torment. Obviously, no one would buy the bottle for 1¢ since he would have to give the bottle away, but no one would accept the bottle knowing he would be unable to get rid of it. Similarly, no one would buy it for 2¢, and so on. However, for some reasonably large amount, it will always be possible to find a next buyer, so the bottle will be bought (Paulos 1995).

Unfinished Game

SHARING PROBLEM

Unfolding

In 1987, K. Fukuda conjectured that no convex polyhedra admit a self-overlapping unfolding The above figure show a counterexample to conjecture 1 found by M. Namiki. A tetrahedron which is also ununfoldable was subsequently found.

Fukuda also conjectured that every CONVEX POLYHEDRON can be uniquely constructed from any of its unfolding. The counterexample shown above was found by T. Matsui.

The question of whether every CONVEX POLYHEDRON admits a self-unoverlapping unfolding is still unsettled.

Unidecagon

HENDECAGON

Uniform Apodization Function

An APODIZATION FUNCTION

$$f(x) = 1, \tag{1}$$

having INSTRUMENT FUNCTION

$$I(x) = \int_{-a}^{a} e^{-2\pi ikx}\, dx = -\frac{1}{2\pi ik}\left(e^{-2\pi ika} - e^{2\pi ikx}\right)$$

$$= \frac{\sin(2\pi ka)}{\pi k} = 2a \operatorname{sinc}(2\pi ka). \tag{2}$$

The peak (in units of a) is 2. The extrema are given by letting $\beta \equiv 2\pi ka$ and solving

$$\frac{d}{d\beta}(\beta \sin \beta) = \frac{\sin \beta - \beta \cos \beta}{\beta^2} = 0 \tag{3}$$

$$\sin \beta - \beta \cos \beta = 0 \tag{4}$$

$$\tan \beta = \beta. \tag{5}$$

Solving this numerically gives $\beta_0 = 0$, $\beta_1 = 4.49341$, $\beta_2 = 7.72525$, ...for the first few solutions. The second of these is the peak POSITIVE sidelobe, and the third is the peak NEGATIVE sidelobe. As a fraction of the peak, they are 0.128375 and –0.217234. The FULL WIDTH AT

HALF MAXIMUM is found by setting $I(x) = 1$

$$\operatorname{sinc}(x) = \tfrac{1}{2}, \tag{6}$$

and solving for $x_{1/2}$, yielding

$$x_{1/2} = 2\pi k_{1/2} a = 1.89549. \tag{7}$$

Therefore, with $L \equiv 2a$,

$$\text{FWHM} = 2k_{1/2} = \frac{0.603353}{a} = \frac{1.20671}{L}. \tag{8}$$

See also APODIZATION FUNCTION

Uniform Boundedness Principle

A "pointwise-bounded" family of continuous linear OPERATORS from a BANACH SPACE to a NORMED SPACE is "uniformly bounded." Symbolically, if $\sup\|T_i(x)\|$ is FINITE for each x in the unit BALL, then $\sup\|T_i\|$ is FINITE. The theorem is also called the BANACH-STEINHAUS THEOREM.

Zeidler, E. *Applied Functional Analysis: Applications to Mathematical Physics.* New York: Springer-Verlag, 1995.

Uniform Convergence

A SERIES $\Sigma_{n=1}^{\infty} u_n(x)$ is uniformly convergent to $S(x)$ for a set E of values of x if, for each $\epsilon > 0$, an INTEGER N can be found such that

$$|S_n(x) - S(x)| < \epsilon \tag{1}$$

for $n \geq N$ and all $x \in E$. To test for uniform convergence, use ABEL'S UNIFORM CONVERGENCE TEST or the WEIERSTRASS M-TEST. If individual terms $u_n(x)$ of a uniformly converging series are continuous, then

1. The series sum

$$f(x) = \sum_{n=1}^{\infty} u_n(x) \tag{2}$$

is continuous,

2. The series may be integrated term by term

$$\int_a^b f(x)\,dx = \sum_{n=1}^{\infty} \int_a^b u_n(x)\,dx, \tag{3}$$

and

3. The series may be differentiated term by term

$$\frac{d}{dx} f(x) = \sum_{n=1}^{\infty} \frac{d}{dx} u_n(x). \tag{4}$$

See also ABEL'S CONVERGENCE THEOREM, ABEL'S UNIFORM CONVERGENCE TEST, WEIERSTRASS M-TEST

Uniform Convexity

This entry contributed by RONALD M. AARTS

To each $\epsilon > 0$, there corresponds a δ such that $\|f - g\| < \epsilon$ whenever $\|f\| = \|g\| = 1$ and $\|(f+g)/2\| > 1 - \delta$. This is a geometric property of the UNIT SPHERE of space: if the MIDPOINT of a LINE SEGMENT with endpoints on the surface of the sphere approaches the surface, then the endpoints must come closer together (Cheney 1999).

References

Cheney, E. W. *Introduction to Approximation Theory, 2nd ed.* Providence, RI: Amer. Math. Soc., 1999.

Uniform Distribution

A distribution which has constant probability is called a uniform distribution, sometimes also called a RECTANGULAR DISTRIBUTION.

The probability density function and cumulative distribution function for a *continuous* uniform distribution are

$$P(x) = \begin{cases} \dfrac{1}{b-a} & \text{for } a < x < b \\ 0 & \text{for } x < a,\ x > b \end{cases} \tag{1}$$

$$D(x) = \begin{cases} 0 & \text{for } x < a \\ \dfrac{x-a}{b-a} & \text{for } a \leq x < b \\ 1 & \text{for } x \geq b. \end{cases} \tag{2}$$

With $a = 0$ and $b = 1$, these can be written

$$P(x) = \Pi\left(x + \tfrac{1}{2}\right) \tag{3}$$

$$= \tfrac{1}{2}[\operatorname{sgn}(x) - \operatorname{sgn}(x-1)] \tag{4}$$

$$= H(x) - H(x-1) \tag{5}$$

$$D(x) = xH(x) + (x-1)H(x-1), \tag{6}$$

where $\Pi(x)$ is the RECTANGLE FUNCTION and $H(x)$ is the HEAVISIDE STEP FUNCTION.

For a *continuous* uniform distribution, the CHARACTERISTIC FUNCTION is

$$\phi(t) = \frac{2}{(b-a)t} \sin\left[\tfrac{1}{2}(b-a)t\right] e^{i(a+b)t/2}, \tag{7}$$

and the MOMENT-GENERATING FUNCTION is

$$M(t) = \langle e^{xt} \rangle = \int_a^b \frac{e^{xt}}{b-a}\,dx = \left[\frac{e^{xt}}{t(b-a)}\right]_a^b, \tag{8}$$

so

$$M(t) = \begin{cases} \dfrac{e^{tb} - e^{ta}}{t(b-a)} & \text{for } t \neq 0 \\ 0 & \text{for } t = 0, \end{cases} \tag{9}$$

and

$$M'(t) = \frac{1}{b-a}\left[\frac{1}{t}\left(be^{bt} - ae^{at}\right) - \frac{1}{t^2}\left(e^{bt} - e^{at}\right)\right]$$

$$= \frac{e^{bt}(bt-1) - e^{at}(at-1)}{(b-a)t^2}. \tag{10}$$

If $a = 0$ and $b = 1$, the CHARACTERISTIC FUNCTION simplifies to

$$\phi(t) = \frac{2\sin\left(\frac{1}{2}t\right)e^{it/2}}{t} = \frac{i - i\cos t + \sin t}{t}. \tag{11}$$

The MOMENT-GENERATING FUNCTION is not differentiable at zero, but the MOMENTS can be calculated by differentiating and then taking $\lim_{t\to 0}$. The RAW MOMENTS are given by

$$\mu'_1 = \tfrac{1}{2}(a+b) \tag{12}$$

$$\mu'_2 = \tfrac{1}{3}\left(a^2 + ab + b^2\right) \tag{13}$$

$$\mu'_3 = \tfrac{1}{4}(a+b)\left(a^2+b^2\right) \tag{14}$$

$$\mu'_4 = \tfrac{1}{5}\left(a^4 + a^3b + a^2b^2 + ab^3 + b^4\right). \tag{15}$$

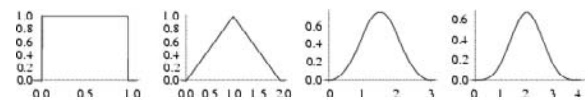
The CENTRAL MOMENTS are then

$$\mu_1 = 0 \tag{16}$$

$$\mu_2 = \tfrac{1}{12}(b-a)^2 \tag{17}$$

$$\mu_3 = 0 \tag{18}$$

$$\mu_4 = \tfrac{1}{80}(b-a)^4, \tag{19}$$



so the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \tfrac{1}{2}(a+b) \tag{20}$$

$$\sigma^2 = \mu_2 = \tfrac{1}{12}(b-a)^2 \tag{21}$$

$$\gamma_1 = \frac{\mu_3}{\sigma^{3/2}} = 0 \tag{22}$$

$$\gamma_2 = -\tfrac{6}{5}. \tag{23}$$

The distribution for the sum of n uniform variates on the interval [0, 1] get be found using the CHARACTERISTIC FUNCTION as

$$P_n(x) = \mathscr{F}^{-1}\left[\left(\frac{i - \cos t + \sin t}{t}\right)^n\right] \tag{24}$$

$$= \frac{1}{2(n-1)!}\sum_{k=0}^{n}(-1)^k\binom{n}{k}(x-k)^{n-1}\operatorname{sgn}(x-k), \tag{25}$$

where the Fourier parameters are taken as (1, 1). The first few values of $P_n(x)$ then give

$$P_1(x) = \tfrac{1}{2}[\operatorname{sgn}(1-x) + \operatorname{sgn} x] \tag{26}$$

$$P_2(x) = \tfrac{1}{2}[(-2+x)\operatorname{sgn}(-2+x)$$

$$-2(-1+x)\operatorname{sgn}(-1+x) + x\operatorname{sgn} x] \tag{27}$$

$$P_3(x) = \tfrac{1}{4}[-(-3+x)^2\operatorname{sgn}(-3+x)$$

$$+3(-2+x)^2\operatorname{sgn}(-2+x)$$

$$-3(-1+x)^2\operatorname{sgn}(-1+x) + x^2\operatorname{sgn} x] \tag{28}$$

$$P_4(x) = \tfrac{1}{12}[(-4+x)^3\operatorname{sgn}(-4+x)$$

$$-4(-3+x)^3\operatorname{sgn}(-3+x)$$

$$+6(-2+x)^3\operatorname{sgn}(-2+x)$$

$$-4(-1+x)^3\operatorname{sgn}(-1+x) + x^3\operatorname{sgn} x], \tag{29}$$

illustrated above.

The probability distribution function and cumulative distributions function for a *discrete* uniform distribution are

$$P(n) = \frac{1}{N} \tag{30}$$

$$D(n) = \frac{n}{N} \tag{31}$$

for $n = 1, \ldots, N$. The MOMENT-GENERATING FUNCTION is

$$M(t) = \langle e^{nt} \rangle = \sum_{n=1}^{N} \frac{1}{N} e^{nt} = \frac{1}{N} \frac{e^t - e^{t(N+1)}}{1 - e^t}$$

$$= \frac{e^t(1 - e^{Nt})}{N(1 - e^t)}. \quad (32)$$

The MOMENTS about 0 are

$$\mu'_m = \frac{1}{N} \sum_{n=1}^{N} n^m, \quad (33)$$

so

$$\mu'_1 = \tfrac{1}{2}(N+1) \quad (34)$$

$$\mu'_2 = \tfrac{1}{6}(N+1)(2N+1) \quad (35)$$

$$\mu'_3 = \tfrac{1}{4} N(N+1)^2 \quad (36)$$

$$\mu'_4 = \tfrac{1}{30}(N+1)(2N+1)\left(3N^2+3N-1\right), \quad (37)$$

and the MOMENTS about the MEAN are

$$\mu_2 = \tfrac{1}{12}(N-1)(N+1) \quad (38)$$

$$\mu_3 = 0 \quad (39)$$

$$\mu_4 = \tfrac{1}{240}(N-1)(N+1)\left(3N^2-7\right). \quad (40)$$

The MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \tfrac{1}{2}(N+1) \quad (41)$$

$$\sigma^2 = \mu_2 = \tfrac{1}{12}(N-1)(N+1) \quad (42)$$

$$\gamma_1 = \frac{\mu_3}{\sigma^{3/2}} = 0 \quad (43)$$

$$\gamma_2 = \frac{6(N^2+1)}{5(N-1)(N+1)}. \quad (44)$$

Uniform Polychoron

A 4-D analog of the UNIFORM POLYHEDRA. In fact, the UNIFORM POLYHEDRA are cells of the uniform polychora. There are more than 8000 known uniform polychora. The vertex figures of uniform polychora are always vertex-inscriptable in hyperspheres.

See also POLYCHORON

References

Olshevsky, G. "Uniform Polytopes in Four Dimensions." http://members.aol.com/Polycell/uniform.html.

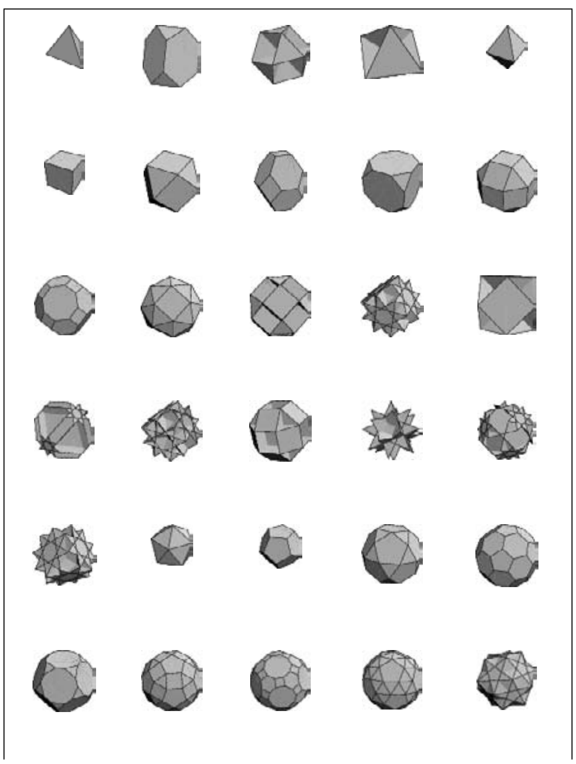
Uniform Polyhedron

The uniform polyhedra are POLYHEDRA with identical VERTICES. Badoureau discovered 37 nonconvex uniform polyhedra in the late nineteenth century, many previously unknown (Wenninger 1983, p. 55). Coxeter *et al.* (1954) conjectured that there are 75 such polyhedra in which only two faces are allowed to meet at an EDGE, and this was subsequently proven. (However, when any EVEN number of faces may meet, there are 76 polyhedra.) If the five pentagonal PRISMS are included, the number rises to 80.

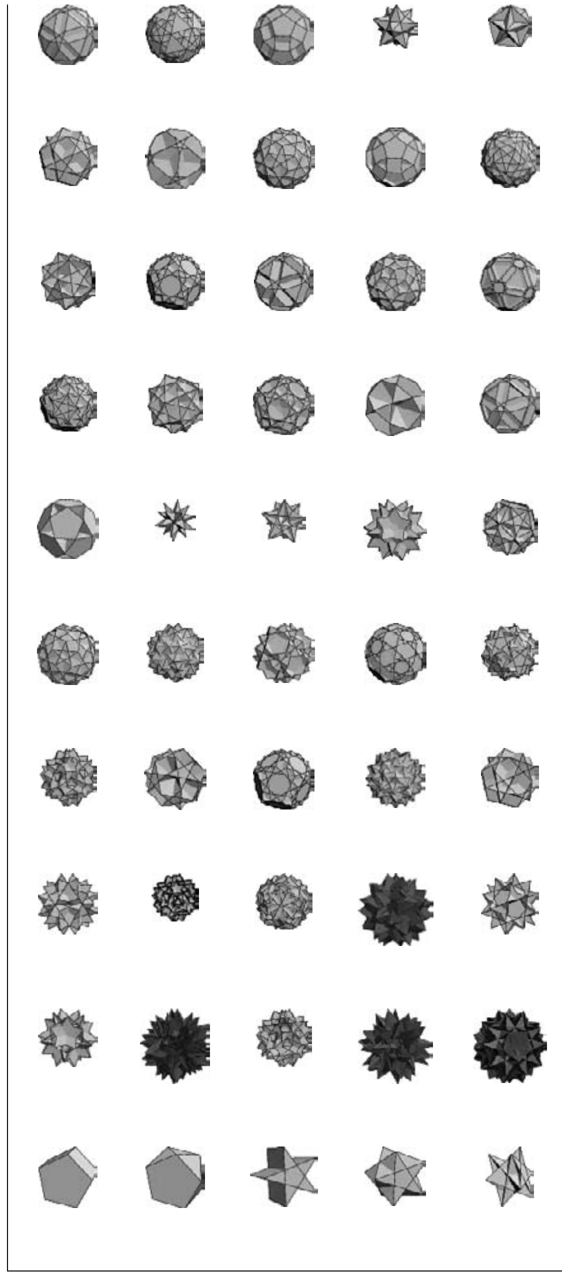
The VERTICES of a uniform polyhedron all lie on a SPHERE whose center is their CENTROID. The VERTICES joined to another VERTEX lie on a CIRCLE.

Except for a single non-Wythoffian case, uniform polyhedra can be generated by Wythoff's kaleidoscopic method of construction. In this construction, an initial vertex inside a special SPHERICAL TRIANGLE PQR is mapped to all the other vertices by repeated reflections across the three planar sides of this triangle. Similarly, PQR and its kaleidoscopic images must cover the sphere an integral number of times which is referred to as the density d of PQR. The density $d > 1$ is dependent on the choice of angles π/p, π/q, π/r at P, Q, R respectively, where p, q, r are reduced rational numbers greater than one. Such a spherical triangle is called a SCHWARZ TRIANGLE, conveniently denoted (pqr). Except for the infinite dihedral family of $(p22)$ for $p = 2, 3, 4, \ldots$, there are only 44 kinds of Schwarz triangles (Coxeter *et al.* 1954, Coxeter 1973). It has been shown that the numerators of p, q, r are limited to 2, 3, 4, 5 (4 and 5 cannot occur together) and so the nine choices for rational numbers are: 2, 3, 3/2, 4, 4/3, 5, 5/2, 5/3, 5/4 (Messer 1999).

The names of the uniform polyhedra were first formalized in Wenninger (1971), based on a list prepared by N. Johnson a few years earlier, as slightly modified by D. Luke. The names of the uniform duals appeared in Wenninger (1983), again based on nomenclature suggested by Johnson. Johnson also suggested a few modifications in the original nomenclature to incorporate some additional thoughts, as well as to undo some of Luke's less felicitous changes. The "List of polyhedra and dual models" in Wenninger (1983) gives revised names for several of the uniform polyhedra.



Source code and binary programs for generating and viewing the uniform polyhedra are also available at http://www.math.technion.ac.il/~rl/kaleido/. The following depictions of the polyhedra were produced by R. Maeder's `UniformPolyhedra.m` package for *Mathematica*. In this package, uniform polyhedra



are computed to the desired numerical precision by numerically solving the definition fundamental equation, and lengths are normalized to give a MIDRADIUS of $\rho = 1$. Due to a limitation in *Mathematica*'s renderer, uniform polyhedra 69, 72, 74, and 75 cannot be displayed using this package (Maeder 1993).

The following table gives the names of the uniform polyhedra and their duals as given in Wenninger (1971). Coxeter *et al.* (1954) give many properties of the uniform solids, and Coxeter *et al.* (1953), Johnson (2000) and Messer give the quartic equation for determining the central angle subtending half an edge. The single non-Wythoffian case is the GREAT DIRHOMBICOSIDODECAHEDRON U_{75} which has pseudo-WYTHOFF SYMBOL |3/2 5/3 3 5/2.

n	WYTHOFF SYMBOL	Name	DUAL POLYHEDRON
1	3 | 2 3	TETRAHEDRON	TETRAHEDRON
2	2 3 | 3	TRUNCATED TETRAHEDRON	TRIAKIS TETRAHEDRON

Johnson (2000) proposed a further revision of the "official" names of the uniform polyhedra and their duals and, at the same time, devised a literal symbol for each uniform polyhedron. For each uniform polyhedron, Johnson (2000) gives its number in Wenninger (1971), a modified SCHLÄFLI SYMBOL (following Coxeter), a literal symbol, and its new designated name. Not every uniform polyhedron has a dual that is free from anomalies like coincident vertices or faces extending to infinity. For those that do, Johnson gives the name of the dual polyhedron. In Johnson's new system, the uniform polyhedra are classified as follows:

1. Regular (regular polygonal vertex figures),
2. Quasi-regular (rectangular or ditrigonal vertex figures),
3. Versi-regular (orthodiagonal vertex figures),
4. Truncated regular (isosceles triangular vertex figures),
5. Quasi-quasi-regular (trapezoidal vertex figures),
6. Versi-quasi-regular (dipteroidal vertex figures),
7. Truncated quasi-regular (scalene triangular vertex figures),
8. Snub quasi-regular (pentagonal, hexagonal, or octagonal vertex figures),
9. Prisms (truncated hosohedra),
10. Antiprisms and crossed antiprisms (snub dihedra)

Here is a brief description of Johnson's symbols for the uniform polyhedra (Johnson). The star operator $*$ appended to "D" or "E" replaces pentagons {5} by pentagrams {5/2}. The bar operator | indicates the removal from a related figure of a set (or sets) of faces, leaving "holes" so that a different set of faces takes their place. Thus, C¦O is obtained from the cuboctahedron CO by replacing the eight triangles by four hexagons. In like manner, rR'¦CO has the twelve squares of the rhombicuboctahedron rCO and the six octagons of the small cubicuboctahedron R'CO but has holes in place of their six squares and eight triangles. The operator "r" stands for "rectified": a polyhedron is truncated to the midpoints of the edges. Operators "a", "b", and "c" in the SCHLÄFLI SYMBOLS for the ditrigonary (i.e., having ditrigonal vertex figures) polyhedra stand for "altered," "blended," and "converted." The operator "o" stands for "ossified" (after S. L. van Oss). Operators "s" and "t" stand for "simiated" (snub) and "truncated."

Primes and capital letters are used for certain operators analogous to those just mentioned. For instance, rXY is the "rhombi-XY," with the faces of the quasi-regular XY supplemented by a set of square "rhombical" faces. The isomorphic r'XY has a crossed vertex figure. The operators "R" and "R'" denote a supplementary set of faces of a different kind–hexagons, octagons or octagrams, decagons or decagrams. Likewise, the operators "T" and "S" indicate the presence of faces other than, or in addition to, those produced by the simpler operators "t" and "s". The vertex figure of s'XY, the "vertisnub XY", is a crossed polygon, and that of s*XY, the "retrosnub XY", has density 2 relative to its circumcenter.

Regular polyhedra: p^q

1	{3, 3}	T	Tetrahedron	Tetrahedron
2	{3, 4}	O	Octahedron	Cube
3	{4, 3}	C	Cube	Octahedron
4	{3, 5}	I	Icosahedron	Dodecahedron
5	{5, 3}	D	Dodecahedron	Icosahedron
20	{5/2, 5}	D*	Small stellated dodecahedron	Great dodecahedron
21	{5, 5/2}	E	Great dodecahedron	Small stellated dodecahedron
22	{5/2, 3}	E*	Great stellated dodecahedron	Great icosahedron
41	{3, 5/2}	J	Great icosahedron	Great stellated dodecahedron

Quasi-regular polyhedra: $(p.q)^r$

11	r{3, 4}	CO	Cuboctahedron	Rhombic dodecahedron
12	r{3, 5}	ID	Icosidodecahedron	Rhombic triacontahedron
73	r{5/2, 5}	ED*	Dodecadodecahedron	Middle rhombic triacontahedron
94	r{5/2, 3}	JE*	Great icosidodecahedron	Great rhombic triacontahedron
70	a{5, 3}	ID*	Small ditrigonary icosidodecahedron	Small triambic icosahedron
80	b{5, 5/2}	DE*	Ditrigonary dodecadodecahedron	Middle triambic icosahedron
87	c{3, 5/2}	JE	Great ditrigonary icosidodecahedron	Great triambic icosahedron

Versi-regular polyhedra: $q.h.q.h$

67	o{3, 3}	T¦T	Tetrahemihexahedron	no dual
78	o{3, 4}	C¦O	Cubohemioctahedron	no dual
68	o{4, 3}	O¦C	Octahemioctahedron	no dual
91	o{3, 5}	D¦I	Small dodecahemidodecahedron	no dual
89	o{5, 3}	I¦D	Small icosahemidodecahedron	no dual
102	o{5/2, 5}	E¦D*	Small dodecahemiicosahedron	no dual
100	o{5, 5/2}	D*¦E	Great dodecahemiicosahedron	no dual
106	o{5/2, 3}	J¦E*	Great icosahemidodecahedron	no dual
107	o{3, 5/2}	E*¦J	Great dodecahemidodecahedron	no dual

Truncated regular polyhedra: $q.2p.2p$

6	t{3, 3}	tT	Truncated tetrahedron	Triakis tetrahedron
7	t{3, 4}	tO	Truncated octahedron	Tetrakis hexahedron

8	t{4, 3}	tC	Truncated cube	Triakis octahedron
92	t'{4, 3}	t'C	stellatruncated cube	Great triakis octahedron
9	t{3, 5}	tI	Truncated icosahedron	Pentakis dodecahedron
10	t{5, 3}	tD	Truncated dodecahedron	Triakis icosahedron
97	t'{5/2, 5}	t'D*	Small stellatruncated dodecahedron	Great pentakis dodecahedron
75	t{5, 5/2}	tE	Great truncated dodecahedron	Small stellapentakis dodecahedron
104	t'{5/2, 3}	t'E*	Great stellatruncated dodecahedron	Great triakis icosahedron
95	t{3, 5/2}	tJ	Great truncated icosahedron	Great stellapentakis dodecahedron

Quasi-quasi-regular polyhedra: $p.2r.q.2r$ and $p.2s.q.2s$

13	rr{3, 4}	rCO	Rhombicuboctahedron	Strombic disdodecahedron
69	R'r{3, 4}	R'CO	Small cubicuboctahedron	Small sagittal disdodecahedron
77	Rr{3, 4}	RCO	Great cubicuboctahedron	Great strombic disdodecahedron
85	r'r{3, 4}	r'CO	Great rhombicuboctahedron	Great sagittal disdodecahedron
14	rr{3, 5}	rID	Rhombicosidodecahedron	Strombic hexecontahedron
72	R'r{3, 5}	R'ID	Small dodekicosidodecahedron	Small sagittal hexecontahedron
71	ra{5, 3}	rID*	Small icosified icosidodecahedron	Small strombic trisicosahedron
82	R'a{5, 3}	R'ID*	Small dodekified icosidodecahedron	Small sagittal trisicosahedron
76	rr{5/2, 5}	rED*	Rhombidodecadodecahedron	Middle strombic trisicosahedron
83	R'r{5/2, 5}	R'ED*	Icosified dodecadodecahedron	Middle sagittal trisicosahedron
81	Rc{3, 5/2}	RJE	Great dodekified icosidodecahedron	Great strombic trisicosahedron
88	r'c{3, 5/2}	r'JE	Great icosified icosidodecahedron	Great sagittal trisicosahedron
99	Rr{5/2, 3}	RJE*	Great dodekicosidodecahedron	Great strombic hexecontahedron
105	r'r{5/2, 3}	r'JE*	Great rhombicosidodecahedron	Great sagittal hexecontahedron

Versi-quasi-regular polyhedra: $2r.2s.2r.2s$

86	or{3, 4}	rR'|CO	Small rhombicube	Small dipteral disdodecahedron
103	Or{3, 4}	Rr'|CO	Great rhombicube	Great dipteral disdodecahedron
74	or{3, 5}	rR'|ID	Small rhombidodecahedron	Small dipteral hexecontahedron
90	oa{5, 3}	rR'|ID*	Small dodekicosahedron	Small dipteral trisicosahedron
96	or{5/2, 5}	rR'|ED*	Rhombicosahedron	Middle dipteral trisicosahedron
101	Oc{3, 5/2}	Rr'|JE	Great dodekicosahedron	Great dipteral trisicosahedron
109	Or{5/2, 3}	Rr'|JE*	Great rhombidodecahedron	Great dipteral hexecontahedron

Truncated quasi-regular polyhedra: $2p.2q.2r$

15	tr{3, 4}	tCO	Truncated cuboctahedron	Disdyakis dodecahedron
93	t'r{3, 4}	t'CO	Stellatruncated cuboctahedron	Great disdyakis dodecahedron
79	Tr{3, 4}	TCO	Cubitruncated cuboctahedron	Trisdyakis octahedron
16	tr{3, 5}	tID	Truncated icosidodecahedron	Disdyakis triacontahedron
98	t'r{5/2, 5}	t'ED*	Stellatruncated dodecadodecahedron	Middle disdyakis triacontahedron
84	T'r{5/2, 5}	T'ED*	Icositruncated dodecadodecahedron	Trisdyakis icosahedron
108	t'r{5/2, 3}	t'JE*	Stellatruncated icosidodecahedron	Great disdyakis triacontahedron

Snub quasi-regular polyhedra: $p.3.q.3.3$ or $p.3.q.3.r.3$

17	sr{3, 4}	sCO	Snub cuboctahedron	Petaloidal disdodecahedron
18	sr{3, 5}	sID	Snub icosidodecahedron	Petaloidal hexecontahedron
110	sa{5, 3}	sID*	Snub disicosidodecahedron	no dual
118	s*a{5, 3}	s*ID*	Retrosnub disicosidodecahedron	no dual
111	sr{5/2, 5}	sED*	Snub dodecadodecahedron	Petaloidal trisicosahedron
114	s'r{5/2, 5}	s'ED*	Vertisnub dodecadodecahedron	Vertipetaloidal trisicosahedron
112	S'r{5/2, 5}	S'ED*	Snub icosidodecadodecahedron	Hexaloidal trisicosahedron
113	sr{5/2, 3}	sJE*	Great snub icosidodecahedron	Great petaloidal hexecontahedron
116	s'r{5/2, 3}	s'JE*	Great vertisnub icosidodecahedron	Great vertipetaloidal hexecontahedron
117	s*r{5/2, 3}	s*JE*	Great retrosnub icosidodecahedron	Great retropetaloidal hexecontahedron

Snub quasi-regular polyhedron: $(p.4.q.4)^2$

119	SSr{5/2, 3}	SSJE*	Great disnub disicosidisdodecahedron	no dual

Prisms: p.4.4

$\{p\}x\{\}$	P(p)	p-gonal prism, $p = 3, 5, 6, \ldots$	p-gonal bipyramid
$\{p/d\}x\{\}$	P(p/d)	d-fold p-gonal prism, $p/d > 2$	d-fold p-gonal bipyramid

Antiprisms and crossed antiprisms: 3.3.3.p

s$\{p\}$h{}	Q(p)	p-gonal antiprism, $p = 4, 5, 6, \ldots$	p-gonal antibipyramid
s$\{p/d\}$h{}	Q(p/d)	d-fold p-gonal antiprism, $p/d > 2$	d-fold p-gonal antibipyramid
s'$\{p/d\}$h{}	Q'(p/d)	d-fold p-gonal crossed antiprism, $2 < p/d < 3$	d-fold p-gonal crossed antibipyramid

Uniform Variate

A random number which lies within a specified range (which can, without loss of generality, be taken as [0, 1]), with a uniform distribution.

Uniformization Theorem

See also Uniformization

Uniformly Cauchy

The series $\Sigma_{j=1}^{\infty} f_j(z)$ is said to be uniformly Cauchy on compact sets if, for each compact $K \subseteq U$ and each $\epsilon > 0$, there exists an $N > 0$ such that for all $M \geq L > N$,

$$\left| \sum_{j=L}^{M} f_j(z) \right| < \epsilon$$

holds (Krantz 1999, p. 104).

Uniformly Distributed Sequence

EQUIDISTRIBUTED SEQUENCE

Unimodal Distribution

A STATISTICAL DISTRIBUTION such as the GAUSSIAN DISTRIBUTION which has a single "peak."

See also BIMODAL DISTRIBUTION

Unimodal Sequence

A finite SEQUENCE which first increases and then decreases. A SEQUENCE $\{s_1, s_2, \ldots, s_n\}$ is unimodal if there exists a t such that

$$s_1 \leq s_2 \leq \ldots \leq s_t$$

and

$$s_t \geq s_{t+1} \geq \ldots \geq s_n.$$

Unimodular Group

A GROUP whose left HAAR MEASURE equals its right HAAR MEASURE.

See also HAAR MEASURE, MODULAR GROUP GAMMA, MODULAR GROUP GAMMA0, MODULAR GROUP LAMBDA

Knapp, A. W. "Group Representations and Harmonic Analysis, Part II." *Not. Amer. Math. Soc.* **43**, 537–49, 1996.

Unimodular Matrix

A MATRIX A with INTEGER elements and DETERMINANT $\det(\mathsf{A}) = \pm 1$, also called a UNIT MATRIX.

The inverse of a unimodular matrix is another unimodular matrix. A POSITIVE unimodular matrix has det $(\mathsf{A}) = +1$. The nth POWER of a POSITIVE UNIMODULAR MATRIX

$$\mathsf{M} = \begin{bmatrix} m_{11} & m_{12} \\ m_{21} & m_{22} \end{bmatrix} \quad (1)$$

is

$$\mathsf{M}^n = \begin{bmatrix} m_{11}U_{n-1}(a) - U_{n-2}(a) & m_{12}U_{n-1}(a) \\ m_{21}U_{n-1}(a) & m_{22}U_{n-1}(a) - U_{n-2}(a) \end{bmatrix}, \quad (2)$$

where

$$a \equiv \tfrac{1}{2}(m_{11} + m_{22}) \quad (3)$$

and the U_n are CHEBYSHEV POLYNOMIALS OF THE SECOND KIND,

$$U_m(x) = \frac{\sin[(m+1)\cos^{-1} x]}{\sqrt{1-x^2}}. \quad (4)$$

See also CHEBYSHEV POLYNOMIAL OF THE SECOND KIND

Unimodular Transformation

A transformation $\mathbf{x}' = \mathsf{A}\mathbf{x}$ is unimodular if the DETERMINANT of the MATRIX A satisfies

$$\det(\mathsf{A}) = \pm 1.$$

A NECESSARY and SUFFICIENT condition that a linear transformation transform a lattice to itself is that the transformation be unimodular.

If z is a COMPLEX NUMBER, then the transformation

$$z' = \frac{az+b}{cz+d}$$

is called a unimodular if a, b, c, and d are integers with $ad - bc = 1$. The set of all unimodular transformations forms a GROUP called the MODULAR GROUP.

See also MODULAR GROUP, MODULAR GROUP GAMMA

Union

The union of two sets A and B is the set obtained by combining the members of each. This is written $A \cup B$, and is pronounced "A union B" or "A cup B." The union of sets A_1 through A_n is written $\cup_{i=1}^{n} A_i$.

Let A, B, C, ... be sets, and let $P(S)$ denote the probability of S. Then

$$P(A \cup B) = P(A) + P(B) - P(A \cap B). \quad (1)$$

Similarly,

$$P(A \cup B \cup C) = P[A \cup (B \cup C)]$$

$$= P(A) + P(B \cup C) - P[A \cap (B \cup C)]$$

$$= P(A) + [P(B) + P(C) - P(B \cap C)]$$
$$- P[(A \cap B) \cup (A \cap C)]$$
$$= P(A) + P(B) + P(C) - P(B \cap C)$$
$$- \{P(A \cap B) + P(A \cap C) - P[(A \cap B) \cap (A \cap C)]\}$$
$$= P(A) + P(B) + P(C) - P(A \cap B)$$
$$- P(A \cap C) - P(B \cap C) + P(A \cap B \cap C). \quad (2)$$

If A and B are DISJOINT SETS, then by definition $P(A \cap B) = 0$, so

$$P(A \cup B) = P(A) + P(B). \quad (3)$$

Continuing, for a set of n disjoint elements $E_1, E_2, ..., E_n$

$$P\left(\bigcup_{i=1}^{n} E_i\right) = \sum_{i=1}^{n} P(E_i), \quad (4)$$

which is the COUNTABLE ADDITIVITY PROBABILITY AXIOM. Now let

$$E_i \equiv A \cap B_i, \quad (5)$$

then

$$P\left(\bigcup_{i=1}^{n} E \cap B_i\right) = \sum_{i=1}^{n} P(E \cap B_i). \quad (6)$$

See also DISJOINT UNION, INTERSECTION, OR, UNION-CLOSED SET

Union-Closed Set

A union-closed set is a nonempty finite collection of distinct nonempty finite sets which is CLOSED under UNION.

See also UNION-CLOSED SETS CONJECTURE

Union-Closed Sets Conjecture

Let $A = \{A_1, A_2, \ldots, A_n\}$ be a UNION-CLOSED SET, then the union-closed set conjecture states that an element exists which belongs to at least $n/2$ of the sets in A. Sarvate and Renaud (1989) showed that the conjecture is true if $|A_1| \leq 2$, where A_1 is the smallest set in A, or if $n < 11$. They also showed that if the conjecture fails, then $|A_1| < |A_n|/2$, where A_n is the largest set of A.

The proof for the case where A has a 2-set can be effected as follows. Write $A_1 = \{x, y\}$, then partition the sets of A into four disjoint families B_0, B_x, B_y, and B_{xy}, according to whether their intersection with A_1 is $\emptyset$, $\{x\}$, $\{y\}$, or $\{x, y\}$, respectively. It follows that $|B_{xy}| \geq |B_0|$ by taking unions with A_1, where $|B|$ is the CARDINALITY of B. Now compare $|B_x|$ with $|B_y|$. If $|B_x| \geq |B_y|$, then $|B_x| + |B_x y| \geq |B_0| + |B_y|$, so x is in at least half the sets of A. Similarly, if $|B_x| \leq |B_y|$, then y is in at least half the sets (Hoey).

Unfortunately, this method of proof does extend to $|A_1| = 3$, since Sarvate and Renaud show an example of a UNION-CLOSED SET with $A_1 = \{x, y, z\}$ where none of x, y, z is in half the sets. However, in these cases, there are other elements which *do* appear in half the sets, so this is not a counterexample to the conjecture, but only a limitation to the method of proof given above (Hoey).

Unit Element

IDENTITY ELEMENT

Unit Fraction

A unit fraction is a FRACTION with NUMERATOR 1. Examples of unit fractions include 1/2, 1/3, 1/12, and 1/123456. Unit fractions are also known as Egyptian fractions as a result of their extensive use by ancient Egyptians as a way of representing other fractions. The famous Rhind papyrus, dated to around 1650 BC, discusses unit fractions and contains a table of representations of $2/n$ as a sum of distinct unit fractions for ODD n between 5 and 101. The reason the Egyptians chose this method for representing fractions is not clear, although André Weil characterized the decision as "a wrong turn" (Hoffman 1998, pp. 153–54). The unique fraction that the Egyptians did not represent using unit fractions was 2/3 (Wells 1986, p. 29).

Unit fractions are almost always required to exclude repeated terms, since representations such as $1/5+1/5+1/5$ are trivial. Any RATIONAL NUMBER has representations as a sum of distinct unit fractions with arbitrarily many terms and with arbitrarily large DENOMINATORS, although for a given fixed number of terms, there are only finitely many. Fibonacci proved that *any* fraction can be REPRESENTED AS a sum of distinct unit fractions (Hoffman 1998, p. 154). An infinite chain of unit fractions can be constructed using the identity

$$\frac{1}{a}=\frac{1}{a+1}+\frac{1}{a(a+1)}. \tag{1}$$

Martin (1999) showed that for every positive RATIONAL NUMBER, there exist representations as unit fractions whose largest DENOMINATOR is at most N and whose DENOMINATORS form a positive proportion of the integers up to N for sufficiently large N. Each FRACTION x/y with y ODD has a unit fraction representation in which each DENOMINATOR is ODD (Breusch 1954; Guy 1994, p. 160). Every x/y has a t-term representation where $t=\mathcal{O}(\sqrt{\log y})$ (Vose 1985).

No algorithm is known for producing unit fraction representations having either a minimum number of terms or smallest possible denominator (Hoffman 1998, p. 155). However, there are a number of ALGORITHMS (including the BINARY REMAINDER METHOD, CONTINUED FRACTION UNIT FRACTION ALGORITHM, GENERALIZED REMAINDER METHOD, GREEDY ALGORITHM, REVERSE GREEDY ALGORITHM, SMALL MULTIPLE METHOD, and SPLITTING ALGORITHM) for decomposing an arbitrary FRACTION into unit fractions. In 1202, Fibonacci published an algorithm for constructing unit fraction representations, and this algorithm was subsequently rediscovered by Sylvester (Hoffman 1998, p. 154; Martin 1999).

Taking the fractions 1/2, 1/3, 2/3, 1/4, 2/4, 3/4, ... (the numerators of which are Sloane's A002260, and the denominators of which are $n-1$ copies of the integer

n), the unit fraction representations using the GREEDY ALGORITHM are

$$\frac{1}{2}=\frac{1}{2}$$
$$\frac{1}{3}=\frac{1}{3}$$
$$\frac{2}{3}=\frac{1}{2}+\frac{1}{6}$$
$$\frac{1}{4}=\frac{1}{4}$$
$$\frac{2}{4}=\frac{1}{2}$$
$$\frac{3}{4}=\frac{1}{2}+\frac{1}{4}$$
$$\frac{1}{5}=\frac{1}{5}$$
$$\frac{2}{5}=\frac{1}{3}+\frac{1}{15}$$
$$\frac{3}{5}=\frac{1}{2}+\frac{1}{10}$$
$$\frac{4}{5}=\frac{1}{2}+\frac{1}{4}+\frac{1}{20}.$$

The number of terms in these representations are 1, 1, 2, 1, 1, 2, 1, 2, 2, 3, 1, ... (Sloane's A050205). The minimum denominators for each representation are given by 2, 3, 2, 4, 2, 2, 5, 3, 2, 2, 6, 3, 2, ... (Sloane's A050206), and the maximum denominators are 2, 3, 6, 4, 2, 4, 5, 15, 10, 20, 6, 3, 2, ... (Sloane's A050210).

Wilf posed as a problem that any fraction with odd denominator can be REPRESENTED AS a sum of unit fractions, each having an odd denominator, and Graham proved that infinitely many fractions with a certain range can be represented as a sum of units fractions with square denominators (Hoffman 1998, p. 156).

Paul Erdos and E. G. Straus have conjectured that the DIOPHANTINE EQUATION

$$\frac{4}{n}=\frac{1}{a}+\frac{1}{b}+\frac{1}{c} \tag{2}$$

always can be solved (Obláth 1950, Rosati 1954, Bernstein 1962, Yamamoto 1965, Vaughan 1970, Guy 1994), and Sierpinski (1956) conjectured that

$$\frac{5}{n}=\frac{1}{a}+\frac{1}{b}+\frac{1}{c} \tag{3}$$

can be solved (Guy 1994).

The HARMONIC NUMBER H_n is never an INTEGER except for H_1. This result was proved im 1915 by Taeisinger, and the more general results that any number of consecutive terms not necessarily starting with 1 never sum to an integer was proved by Kürschák in 1918 (Hoffman 1998, p. 157). In 1932, Erdos proved that the sum of the reciprocals of any number of equally spaced integers is never a reciprocal.

Unit Lattice

A POINT LATTICE which can be constructed from an arbitrary PARALLELOGRAM of unit area. For any such planar lattice, the minimum distance c between any two points is a quantity characteristic of the lattice. This distance satisfies

$$c \leq \sqrt{\frac{2}{\sqrt{3}}}$$

(Hilbert and Cohn-Vossen 1999, p. 36). For a lattice in 3-D,

$$c \leq 2^{1/6}$$

(Hilbert and Cohn-Vossen 1999, p. 45).

Woods, F. S. *Higher Geometry: An Introduction to Advanced Methods in Analytic Geometry.* New York: Dover, p. 9, 1961.

Unit Ring

A unit ring is a set together with two BINARY OPERATORS $S(+, *)$ satisfying the following conditions:

1. Additive associativity: For all $a, b, c \in S$, $(a+b)+c = a+(b+c)$,
2. Additive commutativity: For all $a, b \in S$, $a+b = b+a$,
3. Additive identity: There exists an element $0 \in S$ such that for all $a \in S : 0 + a = a + 0 = a$,
4. Additive inverse: For every $a \in S$, there exists a $-a \in S$ such that $a + (-a) = (-a) + a = 0$,
5. Multiplicative associativity: For all $a, b, c \in S$, $(a * b) * c = a * (b * c)$,
6. Multiplicative identity: There exists an element $1 \in S$ such that for all $a \in S$, $1 * a = a * 1 = a$,
7. Left and right distributivity: For all $a, b, c \in S$, $a * (b + c) = (a * b) + (a * c)$ and $(b + c) * a = (b * a) + (c * a)$.

Thus, a unit ring is a RING with a multiplicative identity.

Unit Square

A SQUARE with side lengths 1. *The* unit square usually means the one with coordinates (0, 0), (1, 0), (1, 1), (0, 1) in the real plane, or 0, 1, $1+i$, and i in the COMPLEX PLANE.

See also HEILBRONN TRIANGLE PROBLEM, UNIT CIRCLE, UNIT CUBE, UNIT DISK

Unit Vector

A VECTOR of unit length, sometimes also called a DIRECTION VECTOR (Jeffreys and Jeffreys 1988). The unit vector $\hat{\mathbf{v}}$ having the same direction as a given (nonzero) vector $\mathbf{v}$ is defined by

$$\hat{\mathbf{v}} \equiv \frac{\mathbf{v}}{|\mathbf{v}|},$$

where $|\mathbf{v}|$ denotes the NORM of $\mathbf{v}$, is the unit vector in the same direction as the (finite) VECTOR $\mathbf{v}$. A unit vector in the $\mathbf{x}_n$ direction is given by

$$\hat{\mathbf{x}}_n \equiv \frac{\frac{\partial \mathbf{r}}{\partial x_n}}{\left|\frac{\partial \mathbf{r}}{\partial x_n}\right|},$$

where $\mathbf{r}$ is the RADIUS VECTOR.

References

Guy, R. K. "Unitary Aliquot Sequences." §B8 in *Unsolved Problems in Number Theory, 2nd ed.* New York: Springer-Verlag, pp. 63–5, 1994.

Unitary Amicable Pair

A PAIR of numbers m and n such that

$$\sigma^*(m) = \sigma^*(n) = m + n,$$

where $\sigma^*(n)$ is the sum of UNITARY DIVISORS. Hagis (1971) and García (1987) give 82 such pairs. The first few are (114, 126), (1140, 1260), (18018, 22302), (32130, 40446), ... (Sloane's A002952 and A002953). The largest known unitary amicable pair, each member of which has 192 digits,

$$\begin{aligned} 2^2 &\cdot 3^2 \cdot 5^9 \cdot 7^3 \cdot 11 \cdot 13 \cdot 17^2 \cdot 19 \cdot 29 \cdot 41 \cdot 43 \cdot 47 \\ &\cdot 79 \cdot 157 \cdot 163 \cdot 223 \cdot 433 \cdot 1303 \cdot 1399 \cdot 2053 \\ &\cdot 2719 \cdot 5167 \cdot 13187 \cdot 16787 \cdot 52747 \cdot 98543 \\ &\cdot 284337 \cdot 500739672615943 \\ &\cdot 7010355416623201 \\ &\cdot 1650696142317348672745 3 \\ &\cdot 1010902824516567500675949172 9 \\ &\cdot \begin{bmatrix} 53 \cdot 9163813886186194062277465733355041 \\ 4948459498540544793629831496011722 67 \end{bmatrix} \end{aligned}$$

(Y. Kohmoto).

Kohmoto calls a unitary amicable pair whose members are squareful a proper unitary amicable pair.

Unitary Divisor

A DIVISOR d of n for which

$$\mathrm{GCD}(d,\ n/d) = 1, \tag{1}$$

where $\mathrm{GCD}(m,\ n)$ is the GREATEST COMMON DIVISOR. For example, the divisors of 12 are $\{1,\ 2,\ 3,\ 4,\ 6,\ 12\}$, so the unitary divisors are $\{1,\ 3,\ 4,\ 12\}$.

Given the PRIME FACTORIZATION

$$n = \prod_{i=1}^{k} p_i^{a_i}, \tag{2}$$

then

$$d = productp_i^{c_i} \tag{3}$$

is a unitary divisor of n if each c_i is 0 or a_i. For a PRIME POWER p^y, the unitary divisors are 1 and p^y (Cohen 1990).

The numbers of unitary divisors of $n = 1, 2, \ldots$ are 1, 2, 2, 2, 2, 4, 2, 2, 2, 4, 2, 4, 2, 4, 4, 2, 2, 4, 2, 4, ... (Sloane's A034444). These numbers are also the numbers of squarefree divisors of n. The number of unitary divisors of n is also given by 2^q, where q is the number of different primes dividing n.

The symbol $\sigma^*(n)$ is used to denote to the UNITARY DIVISOR FUNCTION.

Unitary Divisor Function

The symbol $\sigma^*(n)$ is used to denote to the sum-of-UNITARY DIVISORS function. If n is SQUAREFREE, then $\sigma(n) = \sigma^*(n)$. For $n = 1,\ 2,\ \ldots$, the first few values of $\sigma^*(n)$ are given by 1, 3, 4, 5, 6, 12, 8, 9, 10, 18, 12, ... (Sloane's A034448).

Unitary Group

The unitary group $U_n(q)$ is the set of $n \times n$ UNITARY MATRICES.

See also LIE-TYPE GROUP, UNITARY MATRIX

References

Wilson, R. A. "ATLAS of Finite Group Representation." http://for.mat.bham.ac.uk/atlas/html/contents.html#unit.

Unitary Matrix

A SQUARE MATRIX U is a unitary matrix if

$$\mathsf{U}^* = \mathsf{U}^{-1}, \tag{1}$$

where U^* denotes the ADJOINT MATRIX and U^{-1} is the MATRIX INVERSE. For example,

$$\mathsf{A} = \begin{bmatrix} 2^{-1/2} & 2^{-1/2} & 0 \\ -2^{-1/2}i & 2^{-1/2}i & 0 \\ 0 & 0 & i \end{bmatrix} \tag{2}$$

is a unitary matrix. A matrix m can be tested to see if it is unitary using the *Mathematica* function

```
UnitaryQ[m_List?MatrixQ] :=
          (Conjugate@Transpose@m.m      ==
IdentityMatrix@Length@m)
```

The definition of a unitary matrix guarantees that

$$\mathsf{U}^*\mathsf{U} = \mathsf{I}, \tag{3}$$

where I is the IDENTITY MATRIX. In particular, a unitary matrix is always invertible, and $U^{-1} = U^*$. Note that TRANSPOSE is a much simpler computation than inverse. Unitary matrices leave the length of a COMPLEX VECTOR unchanged. A SIMILARITY TRANSFORMATION of a HERMITIAN MATRIX with a unitary matrix gives

$$\begin{aligned}(uau^{-1})^* &= [(ua)(u^{-1})]^* = (u^{-1})^*(ua)^* = (u^*)^*(a^*u^*) \\ &= uau^* = uau^{-1}. \end{aligned} \tag{4}$$

Unitary matrices are NORMAL MATRICES. If M is a unitary matrix, then the PERMANENT

$$|\mathrm{perm}(\mathsf{M})| \leq 1 \tag{5}$$

(Minc 1978, p. 25, Vardi 1991).

For REAL MATRICES, unitary is the same as ORTHOGONAL. In fact, there are some similarities between ORTHOGONAL MATRICES and unitary matrices. The rows of a unitary matrix are a UNITARY BASIS. That is, each row has length one, and their HERMITIAN INNER PRODUCT is zero. Similarly, the columns are also a unitary basis. In fact, given any unitary basis, the matrix whose rows are that basis is a unitary matrix. It is automatically the case that the columns are another unitary basis.

The unitary matrices are precisely those matrices which preserve the HERMITIAN INNER PRODUCT

$$\langle v, w \rangle = \langle Uv, Uw \rangle. \quad (6)$$

Also, the norm of the determinant of U is $|\det U| = 1$. Unlike the ORTHOGONAL MATRICES, the unitary matrices are CONNECTED. If $\det U = 1$ then U is a SPECIAL UNITARY MATRIX.

The product of two unitary matrices is another unitary matrix. The inverse of a unitary matrix is another unitary matrix, and IDENTITY MATRICES are unitary. Hence the set of unitary matrices form a GROUP, called the UNITARY GROUP.

Unitransitive Graph

A GRAPH G is n-unitransitive if it is CONNECTED, CUBIC, n-TRANSITIVE, and if for any two n-ROUTES W_1 and W_2, there is exactly one automorphism α of G such that $\alpha W_1 = W_2$.

Because there are no n-transitive CUBIC GRAPHS for $n > 5$, there are also no n-unitransitive ones (Harary 1994, p. 175). However, there are n-unitransitive graphs for $n \leq 5$ which are not CAGE GRAPHS (Harary 1994, p. 175). These include the 1-univariate graph of girth 12 on 432 nodes discovered by Frucht (1952), the 2-unitransitive CUBICAL and DODECAHEDRAL GRAPHS, and a set of 3-unitransitive graphs found by Coxeter (1950), one of which is illustrated above (Harary 1994, p. 175).

UnitStep

HEAVISIDE STEP FUNCTION

Unity

The number 1. There are n nth ROOTS OF UNITY, known as the DE MOIVRE NUMBERS.

See also 1, PRIMITIVE ROOT OF UNITY

Univalent

Capable of taking on exactly one possible value.

See also BIVALENT

Univalent Function

A function or transformation f in which $f(z)$ does not overlap z.

In MODULAR FUNCTION theory, a function is called univalent on a subgroup G if it is automorphic under G and VALENCE 1 (Apostol 1997).

See also VALENCE

References

Apostol, T. M. *Modular Functions and Dirichlet Series in Number Theory, 2nd ed.* New York: Springer-Verlag, p. 84, 1997.

Univariate Function

A FUNCTION of a single variable (e.g., $f(x)$, $g(z)$, $\theta(\xi)$, etc.).

See also MULTIVARIATE FUNCTION, UNIVARIATE POLYNOMIAL

Univariate Polynomial

A POLYNOMIAL in a single variable, e.g., $P(x) = a_2x^2 + a_1x + a_0$, as opposed to a MULTIVARIATE POLYNOMIAL, e.g.,

$$P(x, y) = a_{22}x^2y^2 + a_{21}x^2y + a_{12}xy^2 + a_{11}xy + a_{10}x + a_{01}y + a_{00}.$$

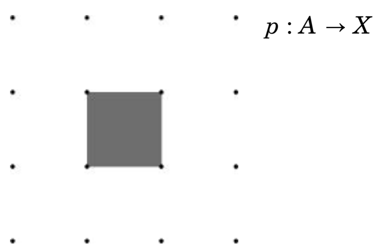
In common usage, if the word "univariate" is not used when describing a POLYNOMIALS, the POLYNOMIALS can assumed to be univariate.

See also MULTIVARIATE POLYNOMIAL, POLYNOMIAL, UNIVARIATE FUNCTION

Universal Algebra

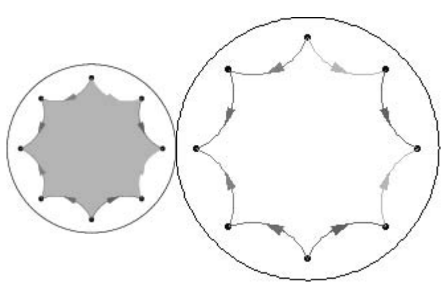
A system of algebra having an empty set of relations. A universal algebra is often simply called an "algebra".

Universal Category



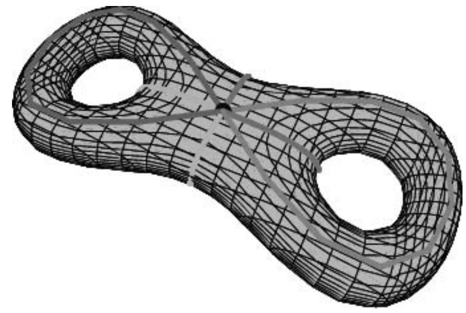
UNIVERSAL PREDICATE

Universal Cover



The universal cover of a CONNECTED TOPOLOGICAL SPACE X is a SIMPLY CONNECTED space Y with a map $f: Y \to X$ that is a COVER. If X is SIMPLY CONNECTED, i.e., has a trivial FUNDAMENTAL GROUP, then it is its own universal cover. For instance, the sphere $\mathbb{S}^2$ is its own universal cover. The universal cover is always

unique, and always exists, as long as X is LOCALLY PATHWISE-CONNECTED (a very mild assumption).



Any property of X can be lifted to its universal cover, as long as it is defined locally. Sometimes, the universal covers with special structures can be classified. For example, a RIEMANNIAN METRIC on X defines a metric on its universal cover. If the metric is FLAT, then its universal cover is EUCLIDEAN SPACE. Another example is the COMPLEX STRUCTURE of a RIEMANN SURFACE X, which also lifts to its universal cover. By the UNIFORMIZATION THEOREM, the only possible universal covers for X are the open unit disk, the complex plane $\mathbb{C}$, or the RIEMANN SPHERE $\mathbb{S}^2$.

The above left diagram shows the universal cover of the torus, i.e., the plane. A fundamental domain, shaded orange, can be identified with the torus. The REAL PROJECTIVE PLANE is the set of lines through the origin, and its universal cover is the sphere, shown in the right figure above. The only nontrivial DECK TRANSFORMATION is the ANTIPODAL MAP.

The compact RIEMANN SURFACES with GENUSES $g > 1$ are g-holed TORI, and their universal covers are the UNIT DISK. The figure above shows a hyperbolic regular octagon in the disk. With the colored edges identified, it is a FUNDAMENTAL DOMAIN for the DOUBLE TORUS. Each hole has two loops, and cutting along each loop yields two edges per loop, or eight edges in total. Each loop is also shown in a different color, and arrows are drawn to provide instructions for lining them up. The FUNDAMENTAL DOMAIN is in gray and can be identified with the DOUBLE TORUS illustrated below. The above animation shows some translations of the fundamental domain by DECK TRANSFORMATIONS, which form a FUCHSIAN GROUP. They tile the disk by analogy with the square tiling the plane for the SQUARE TORUS.

Although it is difficult to visualize a hyperbolic regular octagon in the disk as a cut-up DOUBLE TORUS, the illustration above attempts to portray this. It is unfortunate that no hyperbolic compact manifold with constant negative curvature, can be embedded in $\mathbb{R}^3$. As a result, this picture is not isometric to the hyperbolic regular octagon. However, the generators for the fundamental group are drawn in the same colors, and are examples of so-called cuts of a RIEMANN SURFACE.

Roughly speaking, the universal cover of a space is obtained by the following procedure. First, the space is cut open to make a simply connected space with edges, which then becomes a fundamental domain, as the DOUBLE TORUS is cut to become a hyperbolic octagon or the SQUARE TORUS is cut open to become a square. Then a copy of the fundamental domain is added across an edge. The rule for adding a copy across an edge is that every point has to look the same as the original space, at least nearby. So the copies of the fundamental domain line up along edges which are identified in the original space, but more edges may also line up. Copies of the fundamental domain are added to the resulting space recursively, as long as there remains any edges. The result is a cover, with possibly infinitely many copies of a fundamental domain, which is simply connected.

Any other COVER of X is in turn covered by the universal cover of X, $\tilde{X}$. In this sense, the universal cover is the largest possible cover. In rigorous language, the universal cover has a UNIVERSAL PROPERTY. If $p' : \tilde{X} \to A$ is a COVERING MAP, then there exists a covering map $p \circ \tilde{p}$ such that the composition of p and $\tilde{p}$ is the projection from the universal cover to X.

Universal Graph

COMPLETE GRAPH

Universal Hash Function

Let $h : \{0,\ 1\}^{l(n)} \times \{0,\ 1\}^n \to \{0,\ 1\}^{m(n)}$ be efficiently computable by an algorithm (solving a P-PROBLEM). For fixed $y \in \{0,\ 1\}^{l(n)}$, view $h(x,\ y)$ as a function $h_y(x)$ of x that maps (or hashes) n bits to $m(n)$ bits. Let $Y \in_R \{0,\ 1\}^{l(n)}$, then h is said to be a (pairwise independent) universal hash function if, for distinct $x,\ x' \in \{0,\ 1\}^n$ and for all $a,\ a' \in \{0,\ 1\}^{m(n)}$,

$$\Pr_Y[(h_Y(x) = a) \text{ and } (h_Y(x') = a')] = \frac{1}{2^{2m(n)}},$$

i.e., h_Y maps all distinct $x,\ x'$ independently and uniformly.

These functions are easily constructible (Wegman and Carter 1981, Luby 1996).

Universal Set

A set fixed within the framework of a theory and consisting of all objects considered in this theory.

References

Fraenkel, A. A. and Bar-Hillel, Y. *Foundations of Set Theory.* Amsterdam, Netherlands, 1958.

Universal Space

A TOPOLOGICAL SPACE that contains a homeomorphic image of every topological space of a certain class.

A METRIC SPACE U is said to be universal for a family of METRIC SPACES $\mathcal{M}$ if any space from $\mathcal{M}$ is isometrically embeddable in U. Fréchet (1910) proves that ℓ^∞, the space of all bounded sequences of real numbers endowed with a supremum norm, is a universal space for the family $\mathcal{M}$ of all separable metric spaces. Ovchinnikov (2000) proved that there exists a metric $d \in \mathbb{R}$, inducing the usual topology, such that every finite METRIC SPACE embeds in $(\mathbb{R},\ d)$.

Universe

UNIVERSAL SET

Unknot

A closed loop which is not KNOTTED. In the 1930s, by making use of REIDEMEISTER MOVES, Reidemeister first proved that KNOTS exist which are distinct from the unknot. He proved this by COLORING each part of a knot diagram with one of three colors.

The KNOT SUM of two unknots is another unknot.

The JONES POLYNOMIAL of the unknot is defined to give the normalization

$$V(t) = 1.$$

Haken (1961) devised an ALGORITHM to tell if a knot projection is the unknot. The ALGORITHM is so complicated, however, that it has never been implemented. Although it is not immediately obvious, the unknot is a PRIME KNOT.

See also COLORABLE, KNOT, KNOT THEORY, LINK, REIDEMEISTER MOVES, UNKNOTTING NUMBER

Unknotting Number

The smallest number of times a KNOT must be passed through itself to untie it. Lower bounds can be computed using relatively straightforward techniques, but it is in general difficult to determine exact values. Many unknotting numbers can be determined from a knot's SIGNATURE. A KNOT with unknotting number 1 is a PRIME KNOT (Scharlemann 1985). It is not always true that the unknotting number is achieved in a projection with the minimal number of crossings.

The following table is from Kirby (1997, pp. 88–9), with the values for 10–39 and 10–52 taken from Kawamura. The unknotting numbers for 10–54 and 10–61 can be found using MENASCO'S THEOREM (Stoimenow 1998).

Unlabeled Graph

A GRAPH in which individual nodes have no distinct identifications except through their interconnectivity. Graphs in which labels (which are most commonly numbers) are assigned to nodes are called LABELED GRAPHS. Unless indicated otherwise by context, the unmodified term "graph" generally refers to an *unlabeled* graph.

See also GRAPH, LABELED GRAPH, SIMPLE GRAPH

Unless

If A is true unless B, then not-B IMPLIES A, but B does not necessarily imply not-A.

See also IMPLIES, PRECISELY UNLESS

Unlesss

PRECISELY UNLESS

Unmixed

A homogeneous IDEAL defining a projective ALGEBRAIC VARIETY is unmixed if it has no embedded PRIME divisors.

Unpoke Move

POKE MOVE

Unprojected Map

EQUIRECTANGULAR PROJECTION

Unsafe

A position in a GAME is unsafe for player A if the person who plays next (player B) can win. Every unsafe position can be made SAFE by at least one move.

See also GAME, SAFE

Unsolved Problems

There are many unsolved PROBLEMS in mathematics. Several famous problems which have recently been solved include

1. The PÓLYA CONJECTURE (disproven by Haselgrove 1958, smallest counterexample found by Tanaka in 1980),
2. The FOUR-COLOR THEOREM (by Appel and Haken in 1977 using a computer-assisted proof),
3. The BIEBERBACH CONJECTURE (by L. de Branges in 1985),
4. Tait's FLYPING CONJECTURE (by Menasco and Thistlethwaite in 1991) and the other two of TAIT'S KNOT CONJECTURES (by various authors in 1987),
5. FERMAT'S LAST THEOREM (by A. Wiles and R. Taylor in 1995),
6. The KEPLER CONJECTURE (by T. C. Hales in 1998), and
7. The TANIYAMA-SHIMURA CONJECTURE (by Breuil, Conrad, Diamond, and Taylor in 1999).

Some prominent outstanding unsolved problems (as well as some which are not necessarily so well known) include

1. The GOLDBACH CONJECTURE,
2. The RIEMANN HYPOTHESIS,
3. The POINCARÉ CONJECTURE,
4. The conjecture that there exists a HADAMARD MATRIX for every positive multiple of 4,
5. The TWIN PRIME CONJECTURE (i.e., the conjecture that there are an infinite number of TWIN PRIMES),
6. Determination of whether NP-PROBLEMS are actually P-PROBLEMS,
7. The COLLATZ PROBLEM,
8. Proof that the 196-ALGORITHM does not terminate when applied to the number 196,
9. Proof that 10 is a SOLITARY NUMBER,
10. Finding a formula for the probability that two elements chosen at random generate the SYMMETRIC GROUP S_n,
11. Solving the HAPPY END PROBLEM for arbitrary n,
12. Finding an EULER BRICK whose space diagonal is also an integer,
13. Proving which numbers can be represented as a sum of three or four (positive or negative) CUBIC NUMBERS,
14. LEHMER'S MAHLER MEASURE PROBLEM and LEHMER'S TOTIENT PROBLEM on the existence of COMPOSITE NUMBERS n such that $\phi(n)|(n-1)$, where $\phi(n)$ is the TOTIENT FUNCTION.

The Clay Mathematics Institute of Cambridge, Massachusetts (CMI) has named seven "Millennium Prize Problems," selected by focusing on important classic questions in mathematics that have resisted solution over the years. A $7 million prize fund has been established for the solution to these problems, with $1 million allocated to each. The problems consist of the RIEMANN HYPOTHESIS, POINCARÉ CONJECTURE, HODGE CONJECTURE, SWINNERTON-DYER CONJECTURE, solution of the Navier-Stokes equation, formu-

lation of Yang-Mills theory, and determination of whether NP-PROBLEMS are actually P-PROBLEMS.

In 1900, David Hilbert proposed a list of 23 outstanding problems in mathematics (HILBERT'S PROBLEMS, a number of which have now been solved, but some of which remain open. In 1912, Landau proposed four simply stated problems, now known as LANDAU'S PROBLEMS, which continue to defy attack even today. One hundred years after Hilbert, Smale (2000) proposed a list of 18 outstanding problems.

K. S. Brown, D. Eppstein, S. Finch, and C. Kimberling maintain webpages of unsolved problems in mathematics. Classic texts on unsolved problems in various areas of mathematics are Croft *et al.* (1991), in GEOMETRY, and Guy (1994), in NUMBER THEORY.

Untouchable Number

An untouchable number is an INTEGER which is not the sum of the PROPER DIVISORS of any other number. The first few are 2, 5, 52, 88, 96, 120, 124, 146, ... (Sloane's A005114). Erdos has proven that there are infinitely many. It is thought that 5 is the only ODD untouchable number.

U-Number

ULAM SEQUENCE

UPC

The universal product code (UPC) is a 12-digit number and associated machine-readable bar code used to identify products being purchased in grocery stores. UPCs encode an individual product, but not its price (this part is done by a store's computer after reading the product identifier). The UPC is maintained by the Uniform Code Council of Dayton, Ohio. The first and last digits are separated from the others and written in a smaller font size.

The first six digits are a manufacturer identifier, and the next five digits identify a specific product. The last digit is a check digit obtained from

$$a_{12} = 10 - \left[\left(3 \sum_{\substack{i=1 \\ i \text{ odd}}}^{11} a_i + \sum_{\substack{i=2 \\ i \text{ even}}}^{10} a_i\right) (\text{mod } 10)\right] (\text{mod } 10),$$

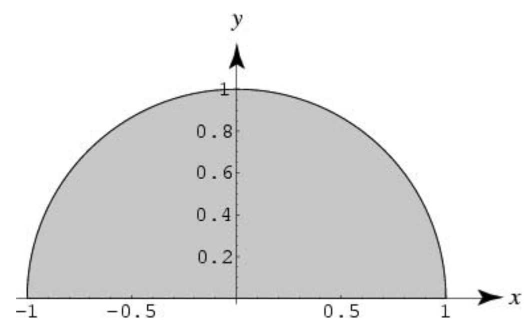
where (mod 10) indicates taking the REMAINDER after dividing by 10. For example, the UPC for *Tropicana* Pure Premium orange juice is

0 48500 00102 8

where the check digit is

$$\begin{aligned} a_{12} &= 10 - [3(0+8+0+0+1+2) \\ &\quad +(4+5+0+0+0) \text{ (mod 10)}] \text{ (mod 10)} \\ &= 10 - [42 \text{ (mod 10)}] \text{ (mod 10)} = 10 - 2 \text{ (mod 10)} \\ &= 8, \end{aligned}$$

as expected.

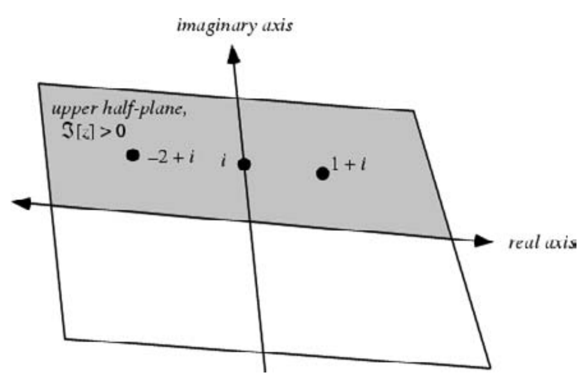


See also CHECKSUM, CODING THEORY, ISBN

Upper Bound

A function f is said to have a upper bound C if $f(x) \leq C$ for all x in its DOMAIN. The LEAST UPPER BOUND is called the SUPREMUM.

See also INEQUALITY, INFIMUM, LEAST UPPER BOUND, LOWER BOUND, SUPREMUM



Upper Half-Disk

The unit upper half-disk is the portion of the COMPLEX PLANE satisfying $\{|z| \leq 1, \ \Im[z] > 0\}$.

See also DISK, LOWER HALF-DISK, REAL AXIS, SEMICIRCLE, UNIT DISK, UPPER HALF-PLANE

Upper Half-Plane

The portion, often denoted H, of the COMPLEX PLANE $\{x+iy : x, \ y \in (-\infty, \ \infty)$ satisfying $y = \Im[z] > 0$ i.e., $H = \{x+iy : x \in (-\infty, \ \infty\}, \ y \in (0, \ \infty)\}$.

Upper Integral

The limit of an UPPER SUM, when it exists, as the MESH SIZE approaches 0.

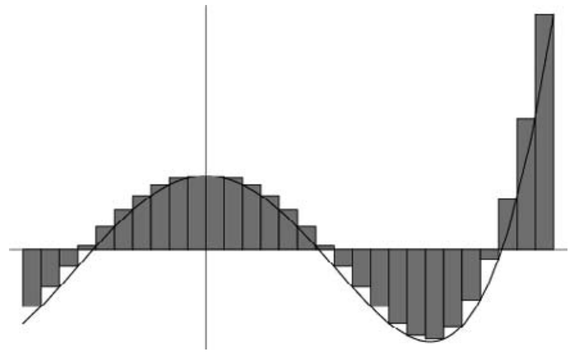
See also LOWER INTEGRAL, RIEMANN INTEGRAL, UPPER SUM

Upper Limit

Let the greatest term H of a SEQUENCE be a term which is greater than all but a finite number of the terms which are equal to H. Then H is called the upper limit of the SEQUENCE.

An upper limit of a SERIES

$$\text{upper} \lim_{n\to\infty} S_n = \overline{\lim_{n\to\infty}} S_n = k$$



is said to exist if, for every $\epsilon > 0$, $|S_n - k| < \epsilon$ for infinitely many values of n and if no number larger than k has this property.

See also LIMIT, LOWER LIMIT, SUPREMUM LIMIT

References

Bromwich, T. J. I'a and MacRobert, T. M. "Upper and Lower Limits of a Sequence." §5.1 in *An Introduction to the Theory of Infinite Series, 3rd ed.* New York: Chelsea, p. 40, 1991.

Upper Sum

For a given function $f(x)$ over a partition of a given interval, the upper sum is the sum of box areas $f(x_k^*)\Delta x_k$ using the greatest value of the function $f(x_k^*)$ in each subinterval Δx_k.

See also LOWER SUM, RIEMANN INTEGRAL, UPPER INTEGRAL

Upper Triangular Matrix

A TRIANGULAR MATRIX U OF THE FORM

$$U_{ij} = \begin{cases} a_{ij} & \text{for } i \leq j \\ 0 & \text{for } i > j. \end{cases}$$

Written explicitly,

$$\mathsf{U} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ 0 & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & a_{nn} \end{bmatrix}.$$

An upper triangular matrix with elements `f[i,j]` above the diagonal can be formed using `UpperDiagonalMatrix[`f, n`]` in the *Mathematica* add-on package `LinearAlgebra`MatrixMultiplication`` (which can be loaded with the command `<<LinearAlgebra``).

HASSE DIAGRAM

Urchin

Kepler's original name for the SMALL STELLATED DODECAHEDRON.

Urelement

An urelement contains no elements, belongs to some set, and is not identical with the EMPTY SET (Moore 1982, p. 3; Rubin 1967, p. 23). "Ur" is a German prefix which is difficult to translate literally, but has a meaning close to "primeval." Urelements are also called "atoms" (Rubin 1967, Moore 1982) or "individuals" (Moore 1982).

In "pure" set theory, all elements are sets and there are no urelements. Often, the axioms of set theory are modified to allow the presence of urelements for ease in representing something. In fact, before Paul Cohen developed the method of forcing, some of the independence theorems in set theory were shown if urelements were allowed.

Utility Graph

The utility problem posits three houses and three utility companies–say, gas, electric, and water–and asks if each utility can be connected to each house without having any of the gas/water/electric lines/pipes pass over any other. This is equivalent to the equation "Can a PLANAR GRAPH be constructed from each of three nodes ('houses') to each of three other nodes ('utilities')?" This problem was first posed in this form by H. E. Dudeney in 1917 (Gardner 1984, p. 92).

The answer is that no such PLANAR GRAPH exists, and the proof can be effected using the JORDAN CURVE THEOREM, while a more general result encompassing this one is the KURATOWSKI REDUCTION THEOREM. The utility graph UG is the graph showing the relationships described above, also known as the THOMSEN GRAPH and, in the more formal parlance of GRAPH THEORY, is known as the COMPLETE BIPARTITE GRAPH $K_{3,\,3}$.

A simple proof of the nonplanarity of the utility graph can be effected by nothing that the graph consists of a GRAPH CYCLE $G-A-W-B-E-C$, to which the three edges $A-E$, $B-G$, and $C-W$ must be added. Now, for each of the edges, we have choose whether to draw the edge inside or outside the GRAPH CYCLE, and so for two of the edges, we must make the same choice. But two lines can't be drawn on the same side without crossing, hence the graph is not planar.

Valuation

A generalization of the P-ADIC NORM first proposed by Kürschák in 1913. A valuation $|\cdot|$ on a FIELD K is a FUNCTION from K to the REAL NUMBERS $\mathbb{R}$ such that the following properties hold for all $x, y \in K$:

1. $|x| \geq 0$,
2. $|x|=0$ IFF $x=0$,
3. $|xy|=|x||y|$,
4. $|x| \leq 1$ IMPLIES $|1+x| \leq C$ for some constant $C \geq 1$ (independent of x).

If (4) is satisfied for $C=2$, then $|\cdot|$ satisfies the TRIANGLE INEQUALITY,

4a. $|x+y| \leq |x|+|y|$ for all $x, y \in K$.

If (4) is satisfied for $C=1$ then $|\cdot|$ satisfies the stronger ULTRAMETRIC inequality

4b. $|x+y| \leq \max(|x|, |y|)$.

The simplest valuation is the ABSOLUTE VALUE for REAL NUMBERS. A valuation satisfying (4b) is called non-ARCHIMEDEAN VALUATION; otherwise, it is called ARCHIMEDEAN.

If $|\cdot|_1$ is a valuation on K and $\lambda \geq 1$, then we can define a new valuation $|\cdot|_2$ by

$$|x|_2 = |x|_1^{\lambda}. \tag{1}$$

This does indeed give a valuation, but possibly with a different constant C in AXIOM 4. If two valuations are related in this way, they are said to be equivalent, and this gives an equivalence relation on the collection of all valuations on K. Any valuation is equivalent to one which satisfies the triangle inequality (4a). In view of this, we need only to study valuations satisfying (4a), and we often view axioms (4) and (4a) as interchangeable (although this is not strictly true).

If two valuations are equivalent, then they are both non-ARCHIMEDEAN or both ARCHIMEDEAN. $\mathbb{Q}$, $\mathbb{R}$, and $\mathbb{C}$ with the usual Euclidean norms are Archimedean valuated fields. For any PRIME p, the P-ADIC NUMBERS $\mathbb{Q}_p$ with the p-adic valuation $|\cdot|_p$ is a NON-ARCHIMEDEAN FIELD.

If K is any FIELD, we can define the trivial valuation on K by $|x|=1$ for all $x \neq 0$ and $|0|=0$, which is a NON-ARCHIMEDEAN VALUATION. If K is a FINITE FIELD, then the only possible valuation over K is the trivial one. It can be shown that any valuation on $\mathbb{Q}$ is equivalent to one of the following: the trivial valuation, Euclidean absolute norm $|\cdot|$, or p-adic valuation $|\cdot|_p$.

The equivalence of any nontrivial valuation of $\mathbb{Q}$ to either the usual ABSOLUTE VALUE or to a P-ADIC NORM was proved by Ostrowski (1935). Equivalent valuations give rise to the same topology. Conversely, if two valuations have the same topology, then they are equivalent. A stronger result is the following: Let $|\cdot|_1$, $|\cdot|_2$, ..., $|\cdot|_k$ be valuations over K which are pairwise inequivalent and let a_1, a_2, ..., a_k be elements of K. Then there exists an infinite sequence $(x_1, x_2, \ldots)$ of elements of K such that

$$\lim_{n\to\infty \text{ w.r.t. } |\cdot|_1} x_n = a_1 \tag{2}$$

$$\lim_{n\to\infty \text{ w.r.t. } |\cdot|_2} x_n = a_2, \tag{3}$$

etc. This says that inequivalent valuations are, in some sense, completely independent of each other. For example, consider the rationals $\mathbb{Q}$ with the 3-adic and 5-adic valuations $|\cdot|_3$ and $|\cdot|_5$, and consider the sequence of numbers given by

$$x_n = \frac{43 \cdot 5^n + 92 \cdot 3^n}{3^n + 5^n}. \tag{4}$$

Then $x_n \to 43$ as $n \to \infty$ with respect to $|\cdot|_3$, but $x_n \to 92$ as $n \to \infty$ with respect to $|\cdot|_5$, illustrating that a sequence of numbers can tend to two different limits under two different valuations.

A discrete valuation is a valuation for which the VALUATION GROUP is a discrete subset of the REAL NUMBERS $\mathbb{R}$. Equivalently, a valuation (on a FIELD K) is discrete if there exists a REAL NUMBER $\varepsilon > 0$ such that

$$|x| \in (1-\varepsilon, 1+\varepsilon) \Rightarrow |x| = 1 \text{ for all } x \in K. \tag{5}$$

The p-adic valuation on $\mathbb{Q}$ is discrete, but the ordinary absolute valuation is not.

If $|\cdot|$ is a valuation on K, then it induces a metric

$$d(x,y) = |x-y| \quad (6)$$

on K, which in turn induces a TOPOLOGY on K. If $|\cdot|$ satisfies (4b), then the metric is an ULTRAMETRIC. We say that $(K, |\cdot|)$ is a complete valuated field if the METRIC SPACE is complete.

Valuation Group

Let $(K,|\cdot|)$ be a valuated FIELD. The valuation group G is defined to be the set

$$G = \{|x| : x \in K, x \neq 0\},$$

with the group operation being multiplication. It is a SUBGROUP of the POSITIVE REAL NUMBERS, under multiplication.

Valuation Ring

Let $(K, |\cdot|)$ be a NON-ARCHIMEDEAN FIELD. Its valuation ring R is defined to be

$$R = \{x \in K : |x| \leq 1\}.$$

The valuation ring has maximal IDEAL

$$M = \{x \in K : |x| \leq 1\},$$

and the FIELD R/M is called the residue field, class field, or field of digits. For example, if $K = \mathbb{Q}_p$ (P-ADIC NUMBERS), then $R = \mathbb{Z}_p$ (p-adic integers), $M = p\mathbb{Z}_p$ (p-adic integers congruent to 0 mod p), and $R/M = \mathrm{GF}(p)$, the FINITE FIELD of order p.

See also P-ADIC NUMBER

Valuation Theory

The study of VALUATIONS which simplifies class field theory and the theory of FUNCTION FIELDS.

Value (Game)

The solution to a GAME in GAME THEORY. When a SADDLE POINT is present

$$\max_{i \leq m} \min_{j \leq n} a_{ij} = \min_{j \leq n} \max_{i \leq m} a_{ij} \equiv v,$$

and v is the value for pure strategies.

See also ABSOLUTE VALUE, GAME THEORY, MINIMAX THEOREM, VALUATION

Vampire Number

A number $v = xy$ with an EVEN number n of DIGITS formed by multiplying a pair of $n/2$-DIGIT numbers (where the DIGITS are taken from the original number in any order) x and y together. Pairs of trailing zeros are not allowed. If v is a vampire number, then x and y are called its "fangs." Examples of vampire numbers include

$$\begin{aligned} 1260 &= 21 \times 60 \\ 1395 &= 15 \times 93 \\ 1435 &= 35 \times 41 \\ 1530 &= 30 \times 51 \\ 1827 &= 21 \times 87 \\ 2187 &= 27 \times 81 \\ 6880 &= 80 \times 86 \end{aligned}$$

(Sloane's A014575). The 8-digit vampire numbers are 10025010, 10042510, 10052010, 10052064, 10081260, ... (Sloane's A048938) and the 10-digit vampire numbers are 1000174288, 1000191991, 1000198206, 1000250010, ... (Sloane's A048939). The numbers of $2n$-digit vampires are 0, 7, 148, 3228, ... (Sloane's A048935).

Vampire numbers having *two* distinct pairs of fangs include

$$125460 = 204 \times 615 = 246 \times 510$$

$$11930170 = 1301 \times 9170 = 1310 \times 9107$$

$$12054060 = 2004 \times 6015 = 2406 \times 5010$$

(Sloane's A048936).

Vampire numbers having *three* distinct pairs of fangs include

$$\begin{aligned} 13078260 &= 1620 \times 8073 = 1863 \times 7020 \\ &= 2070 \times 6318. \end{aligned}$$

(Sloane's A048937).

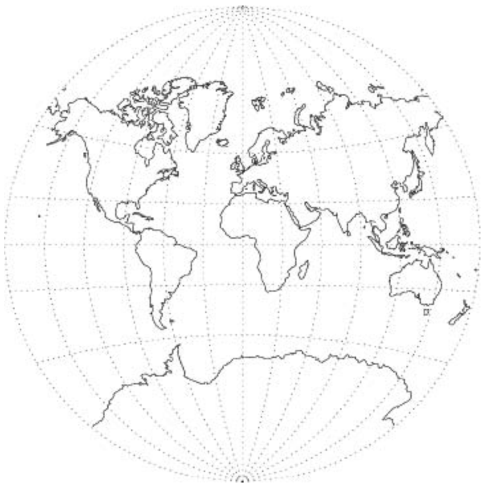
General formulas can be constructed for special classes of vampires, such as the fangs

$$x = 25 \cdot 10^k + 1$$

$$y = 100(10^{k+1} + 52)/25,$$

giving the vampire

$$v = xy = (10^{k+1} + 52)10^{k+2} + 100(10^{k+1} + 52)/25$$
$$= x^* \cdot 10^{k+2} + t$$
$$= 8(26 + 5 \cdot 10^k)(1 + 25 \cdot 10^k),$$



where x^* denotes x with the DIGITS reversed (Roushe and Rogers).

Pickover (1995) also defines pseudovampire numbers, in which the multiplicands have different numbers of digits.

van der Grinten Projection

A MAP PROJECTION given by the transformation

$$x = \operatorname{sgn}(\lambda - \lambda_0) \times \frac{\pi\left[A(G - P^2) + \sqrt{A^2(G - P^2)^2 - (P^2 + A^2)(G^2 - P^2)}\right]}{P^2 + A^2} \quad (1)$$

$$y = \operatorname{sgn}(\phi)\frac{\pi\left[PQ - A\sqrt{(A^2 + 1)(P^2 + A^2) - Q^2}\right]}{P^2 + A^2}, \quad (2)$$

where

$$A = \frac{1}{2}\left|\frac{\pi}{\lambda - \lambda_0} - \frac{\lambda - \lambda_0}{\pi}\right| \quad (3)$$

$$G = \frac{\cos\theta}{\sin\theta + \cos\theta - 1} \quad (4)$$

$$P = G\left(\frac{2}{\sin\theta} - 1\right) \quad (5)$$

$$\theta = \sin^{-1}\left|\frac{2\phi}{\pi}\right| \quad (6)$$

$$Q = A^2 + G. \quad (7)$$

The inverse FORMULAS are

$$\phi = \operatorname{sgn}(y)\pi\left[-m_1\cos\left(\theta_1 + \tfrac{1}{3}\pi\right) - \frac{c_2}{3c_3}\right] \quad (8)$$

$$\lambda = \frac{\pi\left|X^2 + Y^2 - 1 + \sqrt{1 + 2(X^2 - Y^2) + (X^2 + Y^2)^2}\right|}{2X} + \lambda_0, \quad (9)$$

where

$$X = \frac{x}{\pi} \quad (10)$$

$$Y = \frac{y}{\pi} \quad (11)$$

$$c_1 = -|Y|(1 + X^2 + Y^2) \quad (12)$$

$$c_2 = c_1 - 2Y^2 + X^2 \quad (13)$$

$$c_3 = -2c_1 + 1 + 2Y^2 + (X^2 + Y^2)^2 \quad (14)$$

$$d = \frac{Y^2}{c_3} + \frac{1}{27}\left(\frac{2c_2^3}{c_3^3} - \frac{9c_1c_2}{c_3^2}\right) \quad (15)$$

$$a_1 = \frac{1}{c_3}\left(c_1 - \frac{c_2^2}{3c_3}\right) \quad (16)$$

$$m_1 = 2\sqrt{-\tfrac{1}{3}a_1} \quad (17)$$

$$\theta_1 = \tfrac{1}{3}\cos^{-1}\left(\frac{3d}{a_1m_1}\right). \quad (18)$$

van der Pol Equation

An ORDINARY DIFFERENTIAL EQUATION which can be derived from the RAYLEIGH DIFFERENTIAL EQUATION by differentiating and setting $y = y'$. It is an equation describing self-sustaining oscillations in which energy is fed into small oscillations and removed from large oscillations. This equation arises in the study of circuits containing vacuum tubes and is given by

$$y'' - \mu(1-y^2)y' + y = 0.$$

See also RAYLEIGH DIFFERENTIAL EQUATION

van der Waerden Number

This entry contributed by KEVIN O'BRYANT

One form of VAN DER WAERDEN'S THEOREM states that for every POSITIVE INTEGERS k and r, there exists a constant $n(k,r)$ such that if $n_0 \geq n(k,r)$ and $\{1,2,\ldots,n_0\} \subset C_1 \cup C_2 \ldots \cup C_r$, the some set C_i contains an ARITHMETIC SEQUENCE of length k. The least possible value of $n(k,r)$ is known as a van der Waerden number. The only nontrivial van der Waerden numbers that are known exactly are summarized in the following table. As shown in the table, the first few values of $n(2,k)$ for $k = 1, 2, \ldots$ are 1, 3, 9, 35, 178, ... (Sloane's A005346).

$r\backslash k$	$k=3$	$k=4$	$k=5$
$r=2$	9	35	178
$r=3$	27		
$r=4$	76		

Shelah (1988) proved that van der Waerden's numbers are PRIMITIVE RECURSIVE. It is known that

$$n(3,r) \leq e^{r^{c_1}} \tag{1}$$

and that

$$n(4,r) \leq e^{e^{e^{r^{c_2}}}} \tag{2}$$

for some constants c_1 and c_2. In 1998, T. Gowers announced that he has proved the general result

$$n(n,k) \leq e^{e^{(1/r)e^{e^{k+110}}}}, \tag{3}$$

but this work has not yet been published. Berlekamp (1968) showed that for p a prime,

$$n(p+1,2) > p \cdot 2^p, \tag{4}$$

and that probabilistic arguments using the LOVÁSZ LOCAL LEMMA show that

$$n(k,r) > \left(\frac{r^k}{erk}\right)(1+\iota(1)). \tag{5}$$

van der Waerden's Theorem

This entry contributed by KEVIN O'BRYANT

van der Waerden's theorem is a theorem about the existence of arithmetic sequences in sets. The theorem can be stated in three equivalent forms.

1. For every POSITIVE INTEGERS k and r, there exists a constant $n(k,r)$ such that if $n_0 \geq n(k,r)$ and $\{1,2,\ldots,n_0\} \subset C_1 \cup C_2 \ldots \cup C_r$, the some set C_i contains an ARITHMETIC SEQUENCE of length k.
2. If $\{a_0, a_1, \ldots\}$ is an infinite sequence of integers satisfying $0 < a_{k+1} - a_k < r$ for some r, then the sequence contains arbitrarily long arithmetic progressions.
3. For every positive integers k and r, there is a constant $g(k,r)$ such that if $g_0 \geq g(k,r)$ and a_1, a_2, ..., a_{g_0} satisfies $0 < a_{i+1} - a_i \leq r$, then k of the numbers a_1, a_2, ..., a_{g_0} are in arithmetic progression.

The constants $n(k,r)$ are called VAN DER WAERDEN NUMBERS, and no FORMULA for $n(k,r)$ is known. van der Waerden's Theorem is a COROLLARY of SZEMERÉDI'S THEOREM.

van Wijngaarden-Deker-Brent Method

BRENT'S METHOD

Vandermonde Determinant

$$\Delta(x_1, \ldots, x_n) \equiv \begin{vmatrix} 1 & x_1 & x_1^2 & \cdots & x_1^{n-1} \\ 1 & x_2 & x_2^2 & \cdots & x_2^{n-1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & x_n & x_n^2 & \cdots & x_n^{n-1} \end{vmatrix} = \prod_{\substack{i,j \\ i>j}} (x_i - x_j)$$

(Sharpe 1987). For INTEGERS $a_1, ..., a_n$, $\Delta(a_1, \ldots, a_n)$ is divisible by $\prod_{i=1}^{n}(i-1)!$ (Chapman 1996), the first few values of which are the SUPERFACTORIALS 1, 1, 2, 12, 288, 34560, 24883200, 125411328000, ... (Sloane's A000178).

Vandermonde Identity

CHU-VANDERMONDE IDENTITY

Vandermonde Matrix

A type of matrix which arises in the LEAST SQUARES FITTING of POLYNOMIALS and the reconstruction of a STATISTICAL DISTRIBUTION from the distribution's MOMENTS. The solution of an $n \times n$ Vandermonde matrix equation requires $\mathcal{O}(n^2)$ operations. A Vandermonde matrix of order n is OF THE FORM

$$\begin{bmatrix} 1 & x_1 & x_1^2 & \cdots & x_1^{n-1} \\ 1 & x_2 & x_2^2 & \cdots & x_2^{n-1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & x_n & x_n^2 & \cdots & x_n^{n-1} \end{bmatrix}.$$

CHU-VANDERMONDE IDENTITY

Vandiver's Criteria

Let p be an IRREGULAR PRIME, and let $P = rp + 1$ be a PRIME with $P < p^2 - p$. Also let t be an INTEGER such that $t^3 \not\equiv 1 \pmod{P}$. For an IRREGULAR PAIR $(p, 2k)$, form the product

$$Q_{2k} = t^{-rd/2} \prod_{b=1}^{m} (t^{rb} - 1)^{b^{p-1-2k}},$$

where

$$m = \tfrac{1}{2}(p1 - 1)$$

$$d = \sum_{n=1}^{m} n^{p-2k}.$$

If $Q_{2k}^r \not\equiv 1 \pmod{P}$ for all such IRREGULAR PAIRS, then FERMAT'S LAST THEOREM holds for exponent p.

See also FERMAT'S LAST THEOREM, IRREGULAR PAIR, IRREGULAR PRIME

Variance

For N samples of a variate having a distribution with *known* MEAN μ, the "population variance" (usually called "variance" for short, although the word "population" should be added when needed to distinguish it from the SAMPLE VARIANCE) is defined by

$$\operatorname{var}(x) \equiv \frac{1}{N}\sum (x-\mu)^2 = \langle x^2 - 2\mu x + \mu^2 \rangle$$

$$= \langle x^2 \rangle - \langle 2\mu x \rangle + \langle \mu^2 \rangle$$

$$= \langle x^2 \rangle - 2\mu \langle x \rangle + \mu^2, \quad (1)$$

where

$$\langle x \rangle \equiv \frac{1}{N}\sum_{i=1}^{N} x_i. \quad (2)$$

But since $\langle x \rangle$ is an UNBIASED ESTIMATOR for the MEAN

$$\mu \equiv \langle x \rangle, \quad (3)$$

it follows that the variance

$$\sigma^2 \equiv \operatorname{var}(x) = \langle x^2 \rangle - \mu^2. \quad (4)$$

The population STANDARD DEVIATION is then defined as

$$\sigma \equiv \sqrt{\operatorname{var}(x)} = \sqrt{\langle x^2 \rangle - \mu^2}. \quad (5)$$

A useful identity involving the variance is

$$\operatorname{var}(f(x) + g(x)) = \operatorname{var}(f(x)) + \operatorname{var}(g(x)). \quad (6)$$

Therefore,

$$\operatorname{var}(ax+b) = \left\langle [(ax+b) - \langle ax+b \rangle]^2 \right\rangle$$

$$= \left\langle (ax + b - a\langle x \rangle - b)^2 \right\rangle$$

$$= \left\langle (ax - a\mu)^2 \right\rangle = \left\langle a^2(x-\mu)^2 \right\rangle$$

$$= a^2 \left\langle (x-\mu)^2 \right\rangle = a^2 \operatorname{var}(x) \quad (7)$$

$$\operatorname{var}(b) = 0. \quad (8)$$

If the population MEAN is not known, using the sample mean $\bar{x}$ instead of the population mean μ to compute

$$s^2 \equiv \hat{\sigma}_N^2 \equiv \frac{1}{N}\sum_{i=1}^{N}(x_i - \bar{x})^2 \quad (9)$$

gives a BIASED ESTIMATOR of the population variance. In such cases, it is appropriate to use a STUDENT'S T-DISTRIBUTION instead of a GAUSSIAN DISTRIBUTION. However, it turns out (as discussed below) that an UNBIASED ESTIMATOR for the population variance is given by

$$s'^2 \equiv \hat{\sigma}'^2_N \equiv \frac{1}{N-1}\sum_{i=1}^{N}(x_i - \bar{x})^2. \quad (10)$$

For multiple variables, the variance is given using the definition of COVARIANCE,

$$\text{var}\left(\sum_{i=1}^{n} x_i\right) = \text{cov}\left(\sum_{i=1}^{n} x_i, \sum_{j=1}^{m} x_j\right)$$
$$= \sum_{i=1}^{n}\sum_{j=1}^{m} \text{cov}(x_i, x_j)$$
$$= \sum_{i=1}^{n}\sum_{\substack{j=1\\ j=i}}^{m} \text{cov}(x_i, x_j) + \sum_{i=1}^{n}\sum_{\substack{j=1\\ j\neq i}}^{m} \text{cov}(x_i, x_j)$$
$$= \sum_{i=1}^{n} \text{cov}(x_i, x_j) + \sum_{i=1}^{n}\sum_{\substack{j=1\\ j\neq i}}^{m} \text{cov}(x_i, x_j)$$
$$= \sum_{i=1}^{n} \text{var}(x_i) + 2\sum_{i=1}^{n}\sum_{j=i+1}^{m} \text{cov}(x_i, x_j). \tag{11}$$

A linear sum has a similar form:

$$\text{var}\left(\sum_{i=1}^{n} a_i x_i\right) = \text{cov}\left(\sum_{i=1}^{n} a_i x_i, \sum_{j=1}^{m} a_j x_j\right)$$
$$= \sum_{i=1}^{n}\sum_{j=1}^{m} a_i a_j \text{cov}(x_i, x_j)$$
$$= \sum_{i=1}^{n} a_i^2 \text{var}(x_i) + 2\sum_{i=1}^{n}\sum_{j=i+1}^{m} a_i a_j \text{cov}(x_i, x_j). \tag{12}$$

These equations can be expressed using the COVARIANCE MATRIX.

To estimate the POPULATION VARIANCE σ^2 from a sample of N elements with a priori *unknown* MEAN (i.e., the MEAN is estimated from the sample itself), we need an UNBIASED ESTIMATOR for σ^2. This is given by the k-STATISTIC k_2, where

$$\text{var}(s^2) = k_2 = \frac{N}{N-1} s^2 \tag{13}$$

and $m_2 \equiv s^2$ is the SAMPLE VARIANCE, defined by

$$s^2 \equiv \frac{1}{N}\sum_{i=1}^{N}(x_i - \bar{x})^2. \tag{14}$$

The quantity Ns^2/σ^2 has a CHI-SQUARED DISTRIBUTION. Note that some authors prefer the definition

$$s'^2 \equiv \frac{1}{N-1}\sum_{i=1}^{N}(x_i - \bar{x})^2, \tag{15}$$

since this makes the sample variance an UNBIASED ESTIMATOR for the population variance.

To find the variance of the SAMPLE VARIANCE s^2, remember that

$$\text{var}(s^2) \equiv \langle s^4\rangle - \langle s^2\rangle^2, \tag{16}$$

and

$$\langle s^2\rangle = \frac{N-1}{N}\mu_2. \tag{17}$$

Now find $\langle s^4\rangle$:

$$\langle s^4\rangle = \left\langle (s^2)^2\right\rangle = \left\langle \left(\langle x^2\rangle - \langle x\rangle^2\right)^2\right\rangle$$
$$= \left\langle \left[\frac{1}{N}\sum x_i^2 - \left(\frac{1}{N}\sum x_i\right)^2\right]^2\right\rangle$$
$$= \frac{1}{N^2}\left\langle \left(\sum x_i\right)^2\right\rangle - \frac{2}{N^3}\left\langle \sum x_i^2\left(\sum x_i\right)^2\right\rangle + \frac{1}{N^4}$$
$$\times\left\langle \left(\sum x_i\right)^4\right\rangle. \tag{18}$$

Working on the first term of (18),

$$\left\langle \left(\sum x_i^2\right)^2\right\rangle = \left\langle \sum x_i^4 + \sum x_i^2 x_j^2\right\rangle$$
$$= \left\langle \sum x_i^4\right\rangle + \left\langle \sum x_i^2 x_j^2\right\rangle$$
$$= N\langle x_i^4\rangle + N(N-1)\langle x_i^2\rangle\langle x_j^2\rangle$$
$$= N\mu'_4 + N(N-1)\mu_2'^2. \tag{19}$$

The second term of (18) is known from k-STATISTIC,

$$\left\langle \sum x_i^2\left(\sum x_j\right)^2\right\rangle = N\mu'_4 + N(N-1)\mu_2'^2, \tag{20}$$

as is the third term,

$$\left\langle \left(\sum x_i\right)^4\right\rangle = N\left\langle \sum x_i^4\right\rangle + 3N(N-1)\left\langle \sum x_i^2 x_j^2\right\rangle$$
$$= N\mu'_4 + 3N(N-1)\mu_2'^2. \tag{21}$$

Combining (18)-(21) gives

$$\langle s^4\rangle = \frac{1}{N^2}\left[N\mu'_4 + N(N-1)\mu_2'^2\right] - \frac{2}{N^3}$$
$$\times\left[N\mu'_4 + N(N-1)\mu_2'^2\right]$$
$$+\frac{1}{N^4}\left[N\mu'_4 + 3N(N-1)\mu_2'^2\right]$$
$$= \left(\frac{1}{N} - \frac{2}{N^2} + \frac{1}{N^3}\right)\mu'_4$$
$$+\left[\frac{N-1}{N} - \frac{2(N-1)}{N^2} + \frac{3(N-1)}{N^3}\right]\mu_2'^2$$
$$= \left(\frac{N^2-2N+1}{N^3}\right)\mu'_4 + \frac{(N-1)(N^2-2N+3)}{N^3}\mu_2'^2$$

$$= \frac{(N-1)(N-1)\mu_4' + (N^2-2N+3)\mu_2'^2}{N^3} \tag{22}$$

(Kenney and Keeping 1951, p. 164), so plugging in (17) and (22) gives

$$\operatorname{var}(s^2) = \langle s^4 \rangle - \langle s^2 \rangle^2$$

$$= \frac{(N-1)[(N-1)\mu_4' + (N^2-2N+3)\mu_2'^2]}{N^3} - \frac{(N-1)^2 N}{N^3}\mu_2'^2$$

$$= \frac{(N-1)[(N-1)\mu_4' - (N-3)\mu_2'^2]}{N^3}. \tag{23}$$

(Kenney and Keeping 1951, p. 164).

Student calculated the SKEWNESS and KURTOSIS of the distribution of s^2 as

$$\gamma_1 = \sqrt{\frac{8}{N-1}} \tag{24}$$

$$\gamma_2 = \frac{12}{N-1} \tag{25}$$

and conjectured that the true distribution is PEARSON TYPE III DISTRIBUTION

$$f(s^2) = C(s^2)^{(N-3)/2} e^{-Ns^2/2\sigma^2}, \tag{26}$$

where

$$\sigma^2 = \frac{Ns^2}{N-1} \tag{27}$$

$$C = \frac{\left(\frac{N}{2\sigma^2}\right)^{(N-1)/2}}{\Gamma\left(\frac{N-1}{2}\right)}. \tag{28}$$

This was proven by R. A. Fisher.

The distribution of s itself is given by

$$f(s) = 2\frac{\left(\frac{N}{2\sigma^2}\right)^{(N-1)/2}}{\Gamma\left(\frac{N-1}{2}\right)} e^{-ns^2/2\sigma^2} s^{N-2} \tag{29}$$

$$\langle s \rangle = \sqrt{\frac{2}{N}} \frac{\Gamma\left(\frac{N}{2}\right)}{\Gamma\left(\frac{N-1}{2}\right)} \sigma \equiv b(N)\sigma, \tag{30}$$

where

$$b(N) \equiv \sqrt{\frac{2}{N}} \frac{\Gamma\left(\frac{N}{2}\right)}{\Gamma\left(\frac{N-1}{2}\right)}. \tag{31}$$

The MOMENTS are given by

$$\mu_r = \left(\frac{2}{N}\right)^{r/2} \frac{\Gamma\left(\frac{N-1+r}{2}\right)}{\Gamma\left(\frac{N-1}{2}\right)} \sigma^r, \tag{32}$$

and the variance is

$$\operatorname{var}(s) = \nu_2 - \nu_1^2 = \frac{N-1}{N}\sigma^2 - [b(N)\sigma]^2$$

$$= \frac{1}{N}\left[N - 1 - \frac{2\Gamma^2\left(\frac{N}{2}\right)}{\Gamma^2\left(\frac{N-1}{2}\right)}\sigma^2\right] \tag{33}$$

An UNBIASED ESTIMATOR of σ is $s/b(N)$. Romanovsky showed that

$$b(N) = 1 - \frac{3}{4N} - \frac{7}{32N^2} - \frac{139}{51849N^3} + \cdots \tag{34}$$

When computing numerically, the MEAN must be computed before s^2 can be determined. This requires storing the set of sample values. It is possible to calculate s'^2 using a recursion relationship involving only the last sample as follows. Here, use μ_j to denote μ calculated from the first j samples (*not* the jth MOMENT)

$$\mu_j \equiv \frac{\sum_{i=1}^{j} x_i}{j}, \tag{35}$$

and s_j^2 denotes the value for the sample variance s'^2 calculated from the first j samples. The first few values calculated for the MEAN are

$$\mu_1 = x_1 \tag{36}$$

$$\mu_2 = \frac{1 \cdot \mu_1 + x_2}{2} \tag{37}$$

$$\mu_3 = \frac{2\mu_2 + x_3}{3}. \tag{38}$$

Therefore, for $j = 2, 3$ it is true that

$$\mu_j = \frac{(j-1)\mu_{j-1} + x_j}{j} \tag{39}$$

Therefore, by induction,

$$\mu_{j+1} = \frac{[(j+1)-1]\mu_{(j+1)-1} + x_{j+1}}{j+1}$$

$$= \frac{j\mu_j + x_{j+1}}{j+1} \quad (40)$$

$$\mu_{j+1}(j+1) = (j+1)\mu_j + (x_{j+1} - \mu_j) \quad (41)$$

$$\mu_{j+1} = \mu_j + \frac{x_{j+1} - \mu_j}{j+1}, \quad (42)$$

and

$$s_j^2 = \frac{\sum_{i=1}^{j}(x_i - \mu_j)^2}{j-1} \quad (43)$$

for $j \geq 2$, so

$$js_{j+1^2} = j\frac{\sum_{i=1}^{j+1}(x_i - \mu_{j+1})^2}{j} = \sum_{i=1}^{j+1}(x_i - \mu_{j+1})^2$$

$$= \sum_{i=1}^{j+1}\left[(x_i - \mu_j) + (\mu_i - \mu_{j+1})\right]^2$$

$$= \sum_{i=1}^{j+1}(x_i - \mu_j)^2 + \sum_{i=1}^{j+1}(\mu_j - \mu_{j+1})^2 + 2\sum_{i=1}^{j+1}(x_i - \mu_j) \times (\mu_j - \mu_{j+1}). \quad (44)$$

Working on the first term,

$$\sum_{i=1}^{j+1}(x_i - \mu_j)^2 = \sum_{i=1}^{j}(x_i - \mu_j)^2 + (x_{j+1} - \mu_j)^2$$

$$= (j-1)s_j^2 + (x_{j+1} - \mu_j)^2. \quad (45)$$

Use (41) to write

$$x_{j+1} - \mu_j = (j+1)(\mu_{j+1} - \mu_j), \quad (46)$$

so

$$\sum_{i=1}^{j+1}(x_i - \mu_j)^2 = (j-1)s_j^2 + (j+1)^2(\mu_{j+1} - \mu_j)^2. \quad (47)$$

Now work on the second term in (44),

$$\sum_{i=1}^{j+1}(\mu_j - \mu_{j+1})^2 = (j+1)(\mu_j - \mu_{j+1})^2. \quad (48)$$

Considering the third term in (44),

$$\sum_{i=1}^{j+1}(x_i - \mu_j)(\mu_j - \mu_{j+1}) = (\mu_j - \mu_{j+1})\sum_{i=1}^{j+1}(x_i - \mu_j)$$

$$= (\mu_j - \mu_{j+1})\left[\sum_{i=1}^{j}(x_i - \mu_j) + (x_{j+1} - \mu_j)\right]$$

$$= (\mu_j - \mu_{j+1})\left(x_{j+1} - \mu_j - j\mu_j + \sum_{i=1}^{j} x_i\right). \quad (49)$$

But

$$\sum_{i=1}^{j} x_i = j\mu_j, \quad (50)$$

so

$$(\mu_j - \mu_{j+1})(x_{j+1} - \mu_j)$$

$$= (\mu_j - \mu_{j+1})(j+1)(\mu_{j+1} - \mu_j)$$

$$= -(j+1)(\mu_j - \mu_{j+1})^2. \quad (51)$$

Plugging (47), (48), and (51) into (44),

$$js_{j+1^2} = \left[(j-1)s_j^2 + (j+1)^2(\mu_{j+1} - \mu_j)^2\right] + \left[(j+1)(\mu_j - \mu_{j+1})^2\right] + 2\left[-(j+1)(\mu_j - \mu_{j+1})^2\right]$$

$$= (j-1)s_j^2 + (j+1)^2(\mu_{j+1} - \mu_j)^2 - (j+1)(\mu_j - \mu_{j+1})^2$$

$$= (j-1)s_j^2 + (j+1)[(j+1)-1](\mu_{j+1} - \mu_j)^2$$

$$= (j-1)s_j^2 + j(j+1)(\mu_{j+1} - \mu_j)^2, \quad (52)$$

so

$$s_{j+1}^2 = \left(1 - \frac{1}{j}\right)s_j^2 + (j+1)(\mu_{j+1} - \mu_j)^2. \quad (53)$$

Variation

The Δ-variation is a variation in which the varied path over which an integral is evaluated may end at different times than the correct path, and there may be variation in the coordinates at the endpoints.

The δ-variation is a variation in which the varied path in configuration space terminates at the endpoints representing the system configuration at the same time t_1 and t_2 as the correct path; i.e., the varied path always returns to the same endpoints in configuration space, so

$$\delta q_i(t_1) = \delta q_i(t_2) = 0.$$

See also CALCULUS OF VARIATIONS, VARIATION OF ARGUMENT, VARIATION OF PARAMETERS

Variation Coefficient

If s_x is the STANDARD DEVIATION of a set of samples x_i and $\bar{x}$ its MEAN, then

$$V \equiv \frac{s_x}{\bar{x}}.$$

Variation of Argument

Let $[\arg f(z)]$ denote the change in argument of a function $f(z)$ around a CONTOUR γ. Also let N denote the number of ROOTS of $f(z)$ in γ and P denote the number of POLES of $f(z)$ in γ. Then

$$[\arg f(z)] = \frac{1}{2\pi}(N - P). \tag{1}$$

To find $[\arg f(z)]$ in a given region R, break R into paths and find $[\arg f(z)]$ for each path. On a circular ARC

$$z = Re^{i\theta}, \tag{2}$$

let $f(z)$ be a POLYNOMIAL $P(z)$ of degree n. Then

$$[\arg P(z)] = \left[\arg\left(z^n \frac{P(z)}{z^n}\right)\right]$$

$$= [\arg z^n] + \left[\arg\left(\frac{P(z)}{z^n}\right)\right]. \tag{3}$$

Plugging in $z = Re^{i\theta}$ gives

$$[\arg P(z)] = \left[\arg Re^{i\theta n}\right] + \left[\arg \frac{P(Re^{i\theta})}{Re^{i\theta n}}\right] \tag{4}$$

$$\lim_{R\to\infty} \frac{P(Re^{i\theta})}{Re^{i\theta n}} = [\text{constant}], \tag{5}$$

so

$$\left[\frac{P(Re^{i\theta})}{Re^{i\theta n}}\right] = 0, \tag{6}$$

and

$$[\arg P(z)] = \left[\arg e^{i\theta n}\right] = n(\theta_2 - \theta_1). \tag{7}$$

For a REAL segment $z = x$,

$$[\arg f(x)] = \tan^{-1}\left[\frac{0}{f(x)}\right] = 0. \tag{8}$$

For an IMAGINARY segment $z = iy$,

$$[\arg f(iy)] = \left\{\tan^{-1}\frac{\Im[P(iy)]}{\Re[P(iy)]}\right\}_{\theta_1}^{\theta_2}. \tag{9}$$

Note that the ARGUMENT must change continuously, so "jumps" occur across inverse tangent asymptotes.

Variation of Parameters

For a second-order ORDINARY DIFFERENTIAL EQUATION,

$$y'' + p(x)y' + q(x)y = g(x). \tag{1}$$

Assume that linearly independent solutions $y_1(x)$ and $y_2(x)$ are known and seek $v_1(x)$ and $v_2(x)$ such that

$$y^* = v_1 y_1 + v_2 y_2 \tag{2}$$

$$y'^* = (v_1' y_1 + v_2' y_2) + (v_1 y_1' + v_2 y_2'). \tag{3}$$

Now, impose the additional condition that

$$v_1' y_1 + v_2' y_2 = 0 \tag{4}$$

so that

$$y'^*(x) = v_1 y_1' + v_2 y_2' \tag{5}$$

$$y''^*(x) = v_1' y_1' + v_2' y_2' + v_1 y_1'' + v_2 y_2'. \tag{6}$$

Plug y^*, $y^{*\prime}$, and $y^{*\prime\prime}$ back into the original equation to obtain

$$v_1(y_1'' + py_1' + qy_1) + v_2(y_2'' + py_2' + qy_2) + v_1' y_1' + v_2' y_2' = g(x) \tag{7}$$

$$v_1' y_1' + v_2' y_2' = g(x). \tag{8}$$

Therefore,

$$v_1' y_1 + v_2' y_2 = 0 \tag{9}$$

$$v_1' y_1' + v_2' y_2' = g(x). \tag{10}$$

Generalizing to an nth degree ODE, let y_1, ..., y_n be the solutions to the homogeneous ODE and let $v_1'(x)$, ..., $v_n'(x)$ be chosen such that

$$\begin{cases} y_1 v_1' + y_2 v_2' + \ldots + y_n v_n' = 0 \\ y_1' v_1' + y_2' v_2' + \ldots + y_n' v_n' = 0 \\ \vdots \\ y_1^{(n-1)} v_1' + y_2^{(n-1)} v_2' + \ldots + y_n^{(n-1)} v_n' = g(x). \end{cases} \tag{11}$$

Then the particular solution is then

$$y^*(x) = v_1(x) y_1(x) + \ldots + v_n(x) y_n(x). \tag{12}$$

Varignon's Theorem

The figure formed when the MIDPOINTS of the sides of a convex QUADRILATERAL are joined in order is a PARALLELOGRAM. Equivalently, the BIMEDIANS bisect each other. The AREA of this VARIGNON PARALLELOGRAM is half that of the QUADRILATERAL. The PERIMETER is equal to the sum of the diagonals of the original QUADRILATERAL.

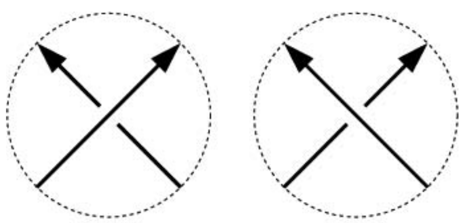
Vassiliev Invariant

This entry contributed by SERGEI DUZHIN

Vassiliev invariants, discovered around 1989, provided a radically new way of looking at KNOTS. The notion of finite type (a.k.a. Vassiliev) KNOT INVARIANTS was independently invented by V. Vassiliev and M. Goussarov around 1989. Vassiliev's approach is based on the study of discriminants in the (infinite-dimensional) spaces of SMOOTH MAPS from one MANIFOLD into another. By definition, the discriminant consists of all maps with SINGULARITIES.

For example, consider the space of all smooth maps from the circle into 3-space $\mathcal{M} = \{f : \mathbb{S}^1 \to \mathbb{R}^3\}$. If f is an EMBEDDING (i.e., has no singular points), then it represents a knot. The complement of the set of all knots is the discriminant $\Sigma \subset \mathcal{M}$. It consists of all smooth maps from $\mathbb{S}^1$ into $\mathbb{R}^3$ that have singularities, either *local*, where $f' = 0$, or *nonlocal*, where f is not injective. Two knots are equivalent IFF they can be joined by a path in the space $\mathcal{M}$ that does not intersect the discriminant. Therefore, knot types are in one-to-one correspondence with the connected components of the complement $\mathcal{M} \setminus \Sigma$, and KNOT INVARIANTS with values in an ABELIAN GROUP G are nothing but COHOMOLOGY CLASSES from $H^0(\mathcal{M} \setminus \Sigma, G)$. The FILTRATION of Σ by subspaces corresponding to SINGULAR KNOTS with a given number of ORDINARY DOUBLE POINTS gives rise to a SPECTRAL SEQUENCE, which contains, in particular, the spaces of finite type invariants.



Birman and Lin (1993) have contributed significantly to the simplification of the Vassiliev's original techniques. In particular, they explained the relation between JONES POLYNOMIALS and finite type invariants (Peterson 1992, Birman and Lin 1993, Bar-Natan 1995) and emphasized the role of the algebra of CHORD DIAGRAMS. In fact, substituting the POWER SERIES for e^x as the variable in the JONES POLYNOMIAL yields a POWER SERIES whose COEFFICIENTS are Vassiliev invariants (Birman and Lin 1993). Kontsevich (1993) proved the first difficult theorem about Vassiliev invariants with the help of the KONTSEVICH INTEGRAL. Bar-Natan undertook a thorough study of

Vassiliev invariants; in particular, he showed the importance of the algebra of Feynman diagrams and diagrams with uni- and tri-valent vertices (Bar-Natan 1995). Bar-Natan (1995) remains the most authoritative source on the subject.

Expressed in simple terms, Vassiliev's fundamental idea is to study the prolongation of KNOT INVARIANTS to SINGULAR KNOTS–immersions $f : \mathbb{S}^1 \to \mathbb{R}^3$ having a finite number of ORDINARY DOUBLE POINTS. Let X_n denote the set of EQUIVALENCE CLASSES of SINGULAR KNOTS with n double points and no other singularities. The following definition is based on a recursion which allows to extend a KNOT INVARIANT from X_0 to X_1, then to X_2, etc., and thus finally to the whole of $X = \cup_n X_n$. Given a knot invariant $v : X_0 \to \mathbb{Q}$, its Vassiliev prolongation $\hat{v} : X \to \mathbb{Q}$ is defined as by the rules

1. $\hat{v}|_X \equiv v$, and

2. $\hat{v}(\otimes) = \hat{v}(\otimes) - \hat{v}(\otimes)$ (Vassiliev's skein relation).

$\epsilon(p) = +1$ $\epsilon(p) = -1$

The right-hand side of Vassiliev's skein relation refers to the two resolutions of the double point–positive and negative. A crucial observation is that each of them is well-defined (does not depend on the plane projection used to express this relation). A KNOT INVARIANT v is called a *Vassiliev invariant of order* $\leq n$ if its prolongation $\hat{v}$ vanishes on all knots with more than n double points. For example, the simplest nontrivial Vassiliev invariant v_2 has the following explicit description. Let D be an arbitrary KNOT DIAGRAM of the given knot K and ★ an arbitrary distinguished point on D, different from all crossings. Then

$$v_2(K) = \sum_{\substack{i\,j\,i\,j\\ UOOU}} \varepsilon_i \varepsilon_j,$$

where the summation spreads over all pairs of crossing points i, j such that (1) during one complete turn of the diagram in the positive direction starting from point ★ the points i and j are encountered in the order i,j,i,j, and (2) the four corresponding passages through these crossing points are underpass, overpass, overpass, and underpass, respectively. The numbers ε_i, ε_j stand for the local WRITHE at points i and j, defined according to the above illustration.

It turns out that the nth coefficient of the CONWAY POLYNOMIAL is a Vassiliev invariant of order n and, in particular, the second coefficient coincides with v_2.

Vassiliev invariants are at least as strong as all known polynomial knot invariants: ALEXANDER, JONES, KAUFFMAN, and HOMFLY POLYNOMIALS. This means that if two knots K_1 and K_2 can be distinguished by such a polynomial, then there is a Vassiliev invariant that takes different values for K_1 and K_2.

The set of all $\mathbb{Q}$-valued Vassiliev invariants $V = \cup_n V_n$ forms a VECTOR SPACE over the rationals, with the increasing FILTRATION $\mathbb{Q} = V_0 \subset V_1 \subset V_2 \subset \ldots$. The ASSOCIATED GRADED SPACE $\bigoplus_n V_n / V_{n-1}$ has a structure of a HOPF ALGEBRA and can be interpreted as the algebra of CHORD DIAGRAMS.

The numbers of independent Vassiliev invariants of a given degree n (i.e., the dimension of V_n) are known for $n = 0$ to 12 (Kneissler 1997) and are summarized in following table (A007473).

n	0	1	2	3	4	5	6	7	8	9	10	11	12
dim V_n	1	1	2	3	6	10	19	33	60	104	184	316	548

The totality of all Vassiliev invariants is equivalent to one UNIVERSAL VASSILIEV INVARIANT defined through the KONTSEVICH INTEGRAL.

Two of the most important problems about Vassiliev invariants were raised in 1990 and remain unanswered today.

1. Is it true that Vassiliev invariants distinguish knots? In other words, given two nonequivalent knots K_1 and K_2, is it always possible to indicate a finite type invariant v such that $v(K_1) \neq v(K_2)$?
2. Is it true that Vassiliev invariants can detect knot orientation? More specifically, is there a knot K and a finite type invariant v such that $v(K) \neq v(\bar{K})$, where $\bar{K}$ differs from K by a change of parameterization that reverses the orientation?

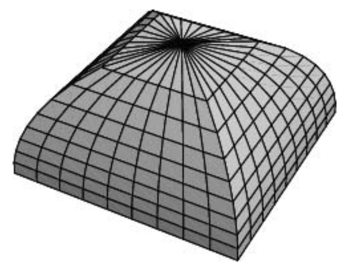
Vassiliev Polynomial

Vassiliev (1990) introduced a radically new way of looking at KNOTS by considering a multidimensional space in which each point represents a possible 3-D knot configuration. If two KNOTS are equivalent, a path then exists in this space from one to the other. The paths can be associated with polynomial invariants.



Birman and Lin (1993) subsequently found a way to translate this scheme into a set of rules and list of potential starting points, which makes analysis of Vassiliev polynomials much simpler. Bar-Natan (1995) and Birman and Lin (1993) proved that JONES POLYNOMIALS and several related expressions are directly connected (Peterson 1992). In fact, substituting the POWER SERIES for $\mathbb{R}^3$ as the variable in the JONES POLYNOMIAL yields a POWER SERIES whose COEFFICIENTS are Vassiliev polynomials (Birman and Lin 1993). Bar-Natan (1995) also discovered a link with Feynman diagrams (Peterson 1992).

Vault

Let a vault consist of two equal half-CYLINDERS of radius r which intersect at RIGHT ANGLES so that the lines of their intersections (the "groins") terminate in the VERTICES of a SQUARE. Two vaults placed bottom-to-top form a STEINMETZ SOLID on two cylinders.

Solving the equations

$$x^2+z^2=r^2 \tag{1}$$

$$y^2+z^2=r^2 \tag{2}$$

simultaneously gives

$$x=\pm\sqrt{r^2-z^2} \tag{3}$$

$$y=\pm\sqrt{r^2-z^2}. \tag{4}$$

One quarter of the vault can therefore be described by the PARAMETRIC EQUATIONS

$$x=\sqrt{r^2-z^2} \tag{5}$$

$$y=-u\sqrt{r^2-z^2} \tag{6}$$

$$z=z. \tag{7}$$

The SURFACE AREA of the vault is therefore given by

$$A=4\int l(z)r\,d\theta, \tag{8}$$

where $l(z)$ is the length of a cross section at height z and θ is the angle a point on the center of this line makes with the origin. But $z=r\sin\theta$, so

$$dz=r\cos\theta\,d\theta=r\sqrt{1-\sin^2\theta}\,d\theta=\sqrt{r^2-z^2}\,d\theta,$$

and

$$l(z) = 2\sqrt{r^2 - x^2} \tag{9}$$

$$A = 4\int_0^r 2r\sqrt{r^2 - z^2}\,\frac{dz}{\sqrt{r^2 - z^2}} = 4\int_0^r 2r\,dz = 8r^2. \tag{10}$$

The VOLUME of the vault is

$$V = \int_0^r \left(2\sqrt{r^2 - z^2}\right)^2 dz = \tfrac{8}{3}r^3. \tag{11}$$

Vector

A vector is formally defined as an element of a VECTOR SPACE. In the commonly encountered VECTOR SPACE $\mathbb{R}^n$ (i.e., Euclidean n-space), a vector is given by n coordinates and can be specified as $(A_1, A_2, \ldots, A_n)$. Vectors can be added together (VECTOR ADDITION) and multiplied by SCALARS (SCALAR MULTIPLICATION). VECTOR MULTIPLICATION is not uniquely defined, but a number of different types of products, such as the DOT PRODUCT, CROSS PRODUCT, TENSOR DIRECT PRODUCT can be defined for pairs of vectors.

A vector from a point A to a point B is denoted $\overrightarrow{AB}$, and a vector v may be denoted $\vec{v}$, or more commonly, $\mathbf{v}$. The point A is often called the "tail" of the vector, and B is called the vector's "head." A vector with unit length is called a UNIT VECTOR and is denoted using a HAT, $\hat{\mathbf{v}}$. An arbitrary vector may be converted to a UNIT VECTOR by dividing by its NORM (i.e., length),

$$|v| \equiv \sqrt{v_1^2 + v_2^2 + \ldots + v_n^2}, \tag{1}$$

giving

$$\hat{\mathbf{v}} \equiv \frac{\mathbf{v}}{|\mathbf{v}|} \tag{2}$$

A ZERO VECTOR, denoted 0, is a vector of length 0, and thus has all components equal to zero.

Since vectors remain unchanged under TRANSLATION, it is often convenient to consider the tail A as located at the origin when, for example, defining VECTOR ADDITION and SCALAR MULTIPLICATION.

A vector may also be defined as a set of n numbers A_0, ..., A_n that transform according to the rule

$$A_i' = a_{ij}A_j, \tag{3}$$

where EINSTEIN SUMMATION notation has been used,

$$a_{ij} = \frac{\partial x_i'}{\partial x_j} = \frac{\partial x_j}{\partial x_i'} \tag{4}$$

are constants (corresponding to the DIRECTION COSINES), with partial derivatives taken with respect to the original and transformed coordinate axes, and $i, j = 1, \ldots, n$ (Arfken 1985, p. 10). This makes a vector a TENSOR of RANK one. A vector with n components in called an n-vector, and a SCALAR may therefore be thought of as a 1-vector (or a 0-RANK TENSOR). Vectors are invariant under TRANSLATION, and they reverse sign upon inversion. Objects which resemble vectors but do not reverse sign upon inversion are known as PSEUDOVECTORS.

A vector is represented in *Mathematica* as a list of numbers {*a1*, *a2*, ..., *an*}. VECTOR ADDITION is then simply written using a plus sign, e.g., {*a1*, *a2*, ..., *an*}+{*b1*, *b2*, ..., *bn* }, and SCALAR MULTIPLICATION is indicated by placing a scalar next to a vector (with or without an optional asterisk), *s*{*a1*, *a2*, ..., *an*}.

Let $\hat{\mathbf{n}}$ be the UNIT VECTOR defined in SPHERICAL COORDINATES by

$$\hat{\mathbf{n}} \equiv \begin{bmatrix} \cos\theta\sin\phi \\ \sin\theta\sin\phi \\ \cos\phi \end{bmatrix}. \tag{5}$$

Then the average value of the x-component of the $\hat{\mathbf{n}}$ over the surface of the UNIT SPHERE is given by

$$\langle n_x \rangle = \frac{\int_0^{2\pi}\int_0^{\pi} (\cos\theta\sin\phi)\sin\phi\,d\phi\,d\theta}{f_0^{2\pi} f_0^{\pi} \sin\phi\,d\phi\,d\theta}$$

$$= \frac{1}{4\pi}[\sin\theta]_0^{2\pi}\int_0^{2\pi}\sin^2\phi\,d\phi = 0. \tag{6}$$

More generally,

$$\langle n_i \rangle = 0 \tag{7}$$

for $i = x$, y, or z (indexed as 1, 2, 3), and

$$\langle n_i n_j \rangle = \tfrac{1}{3}\delta_{ij} \tag{8}$$

$$\langle n_i n_j n_k \rangle = 0 \tag{9}$$

$$\langle n_i n_k n_l n_m \rangle = \tfrac{1}{15}(\delta_{ik}\delta_{lm} + \delta_{il}\delta_{km} + \delta_{im}\delta_{kl}). \tag{10}$$

Given vectors $\mathbf{a}$, $\mathbf{b}$, $\mathbf{c}$, $\mathbf{d}$, the average values of a number of quantities over the UNIT SPHERE are given by

$$\left\langle (\mathbf{a}\cdot\hat{\mathbf{n}})^2 \right\rangle = \tfrac{1}{3}a^2 \tag{11}$$

$$\langle (\mathbf{a}\cdot\hat{\mathbf{n}})(\mathbf{b}\cdot\hat{\mathbf{n}}) \rangle = \tfrac{1}{3}\mathbf{a}\cdot\mathbf{b} \tag{12}$$

$$\langle(\mathbf{a}\cdot\hat{\mathbf{n}})\hat{\mathbf{n}}\rangle = \tfrac{1}{3}\mathbf{a} \quad (13)$$

$$\left\langle(\mathbf{a}\times\hat{\mathbf{n}})^2\right\rangle = \tfrac{2}{3}a^2 \quad (14)$$

$$\langle(\mathbf{a}\times\hat{\mathbf{n}})\cdot(\mathbf{b}\times\hat{\mathbf{n}})\rangle = \tfrac{2}{3}\mathbf{a}\cdot\mathbf{b}, \quad (15)$$

and

$$\langle(\mathbf{a}\cdot\hat{\mathbf{n}})(\mathbf{b}\cdot\hat{\mathbf{n}})(\mathbf{c}\cdot\hat{\mathbf{n}})(\mathbf{d}\cdot\hat{\mathbf{n}})\rangle$$

$$= \tfrac{1}{15}[(\mathbf{a}\cdot\mathbf{d})(\mathbf{c}\cdot\mathbf{d}) + (\mathbf{a}\cdot\mathbf{c})(\mathbf{b}\cdot\mathbf{d}) + (\mathbf{a}\cdot\mathbf{d})(\mathbf{b}\cdot\mathbf{c})] \quad (16)$$

where δ_{ij} is the KRONECKER DELTA, $\mathbf{a}\cdot\mathbf{b}$ is a DOT PRODUCT, and EINSTEIN SUMMATION has been used.

A MAP $\mathbf{f}: \mathbb{R}^n \mapsto \mathbb{R}^n$ which assigns each $\mathbf{x}$ a VECTOR FUNCTION $\mathbf{f}(\mathbf{x})$ is called a VECTOR FIELD.

Vector Addition

The so-called PARALLELOGRAM LAW gives the rule for vector addition of vectors **A** and **B**. The sum **A** + **B** of the vectors is obtained by placing them head to tail and drawing the vector from the free tail to the free head.

Vector addition is indicated in *Mathematica* using a plus sign, e.g., {*a1*, *a2*, ..., *an*} + {*b1*, *b2*, ..., *bn* }.

See also COMPLEX ADDITION, CROSS PRODUCT, DOT PRODUCT, PARALLELOGRAM LAW, SCALAR MULTIPLICATION, VECTOR, VECTOR MULTIPLICATION

Vector Basis

A vector basis is any SET of n LINEARLY INDEPENDENT VECTORS capable of generating an n-dimensional SUBSPACE of $\mathbb{R}^n$. Given a HYPERPLANE defined by

$$x_1 + x_2 + x_3 + x_4 + x_5 = 0,$$

a basis is found by solving for x_1 in terms of x_2, x_3, x_4, and x_5. Carrying out this procedure,

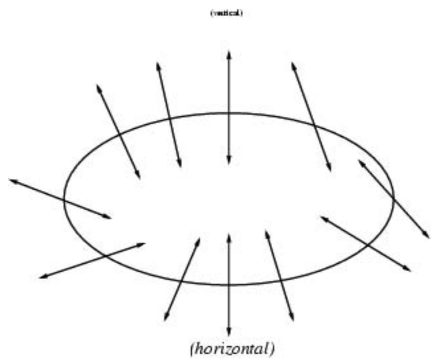
$$x_1 = -x_2 - x_3 - x_4 - x_5,$$

so

$$\begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix} = x_2 \begin{bmatrix} -1 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix} + x_3 \begin{bmatrix} -1 \\ 0 \\ 1 \\ 0 \\ 0 \end{bmatrix} + x_4 \begin{bmatrix} -1 \\ 0 \\ 0 \\ 1 \\ 0 \end{bmatrix} + x_5 \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \\ 1 \end{bmatrix},$$

and the above VECTOR form an (unnormalized) BASIS. Given a MATRIX A with an orthonormal basis, the MATRIX corresponding to a new basis, expressed in terms of the original $\hat{\mathbf{x}}_1, \ldots, \hat{\mathbf{x}}_n$ is

$$\mathsf{A}' = [\mathsf{A}\hat{\mathbf{x}}_1 \quad \ldots \quad \mathsf{A}\hat{\mathbf{x}}_n]$$



See also BASIS, BILINEAR BASIS, MODULAR SYSTEM BASIS, ORTHONORMAL BASIS, TOPOLOGICAL BASIS

Vector Bundle

A special class of FIBER BUNDLE in which the FIBER is a VECTOR SPACE V. Technically, a little more is required; namely, if $f: E \to B$ is a BUNDLE with FIBER $\mathbb{R}^n$, to be a vector bundle, all of the FIBERS $f^{-1}(x)$ for

$x \in B$ need to have a coherent VECTOR SPACE structure. One way to say this is that the "TRIVIALIZATIONS" $h : f^{-1}(U) \to U \times \mathbb{R}^n$, are FIBER-for-FIBER VECTOR SPACE ISOMORPHISMS.

A vector bundle is a TOTAL SPACE E along with a SURJECTIVE map $\pi : E \to B$ to a base manifold B. Any FIBER $\pi^{-1}(b)$ is a VECTOR SPACE ISOMORPHIC to V.

nontrivial line bundle on the circle

The simplest nontrivial vector bundle is a LINE BUNDLE on the circle, and is analogous to the MÖBIUS STRIP.

One use for vector bundles is a generalization of VECTOR FUNCTIONS. For instance, the tangent vectors of an n-dimensional manifold are isomorphic to $\mathbb{R}^n$ at a point p in a COORDINATE CHART. But the isomorphism with $\mathbb{R}^n$ depends on the choice of COORDINATE CHART. Nearby p, the vector fields look like functions. To define vector fields on the whole manifold requires the TANGENT BUNDLE, which is a special case of a vector bundle.

A SECTION of a vector bundle E is a map $s : B \to E$ whose projection, $\pi \circ s$ is the identity map on B. For instance, on a TRIVIAL BUNDLE $E = B \times V$, a section s corresponds to a function $f : B \to V$ by $s(b) = (b, f(b))$.

Near every point in a vector bundle, there is a TRIVIALIZATION. The structure of the vector bundle, as in all BUNDLES, is that it is LOCALLY TRIVIAL. In the case of a vector bundle, the TRANSITION FUNCTIONS between the trivializations take values in linear invertible transformations of the fiber.

Since the element zero in V is fixed by any linear transformation, the zero section always exists. By "nontrivial section," it is meant that it is not the zero section.

There are several adjectives that can specify properties of a vector bundle. A COMPLEX VECTOR BUNDLE has a fiber V which is a COMPLEX VECTOR SPACE. A REAL VECTOR BUNDLE has a fiber which is a real VECTOR SPACE, which is the default kind of vector bundle. A LINE BUNDLE has a fiber which is one dimensional.

A CONTINUOUS VECTOR BUNDLE is a manifold E with a CONTINUOUS projection map π. A SMOOTH VECTOR BUNDLE is a smooth manifold E with a smooth projection π. Finally, a HOLOMORPHIC VECTOR BUNDLE is a COMPLEX MANIFOLD E with a HOLOMORPHIC projection π. In this last case, the fiber must be a complex vector space. So there could be a smooth complex vector bundle, but not a holomorphic real vector bundle.

Vector bundles can have metrics on their fibers, either RIEMANNIAN or HERMITIAN, and CONNECTIONS.

Vector Cross Product

CROSS PRODUCT

Vector Derivative

The basic types of derivatives operating on a VECTOR FIELD are the CURL $\nabla\times$, DIVERGENCE $\nabla\cdot$, and GRADIENT ∇.

Vector derivative identities involving the CURL include

$$\nabla \times (k\mathbf{A}) = k\nabla \times \mathbf{A} \tag{1}$$

$$\nabla \times (f\mathbf{A}) = f(\nabla \times \mathbf{A}) + (\nabla f) \times \mathbf{A} \tag{2}$$

$$\nabla \times (\mathbf{A} \times \mathbf{B}) = (\mathbf{B} \cdot \nabla)\mathbf{A} - (\mathbf{A} \cdot \nabla)\mathbf{B} + \mathbf{A}(\nabla \cdot \mathbf{B}) - \mathbf{B}(\nabla \cdot \mathbf{A}) \tag{3}$$

$$\nabla \times \left(\frac{\mathbf{A}}{f}\right) = \frac{f(\nabla \times \mathbf{A}) + \mathbf{A} \times (\nabla f)}{f^2} \tag{4}$$

$$\nabla \times (\mathbf{A} + \mathbf{B}) = \nabla \times \mathbf{A} + \nabla \times \mathbf{B}. \tag{5}$$

In CARTESIAN COORDINATES

$$\nabla \times \mathbf{x} = \nabla \times \mathbf{y} = \nabla \times \mathbf{z} = \mathbf{0} \tag{6}$$

$$\nabla \times \hat{\mathbf{x}} = \nabla \times \hat{\mathbf{y}} = \nabla \times \hat{\mathbf{z}} = \mathbf{0}. \tag{7}$$

In SPHERICAL COORDINATES,

$$\nabla \times \mathbf{r} = \mathbf{0} \tag{8}$$

$$\nabla \times \hat{\mathbf{r}} = \mathbf{0} \tag{9}$$

$$\nabla \times [\mathbf{r}f(r)] = f(r)(\nabla \times \mathbf{r}) + [\nabla f(r)] \times \mathbf{r} = f(r)(\mathbf{0}) + \frac{df}{dr}\hat{\mathbf{r}} \times \mathbf{r} = \mathbf{0} + \mathbf{0} = \mathbf{0}. \tag{10}$$

Vector derivative identities involving the DIVERGENCE include

$$\nabla \cdot (k\mathbf{A}) = k\nabla \cdot \mathbf{A} \tag{11}$$

$$\nabla\cdot(f\mathbf{A})=f(\nabla\cdot\mathbf{A})+(\nabla f)\cdot\mathbf{A} \quad (12)$$

$$\nabla\cdot(\mathbf{A}\times\mathbf{B})=\mathbf{B}\cdot(\nabla\times\mathbf{A})-\mathbf{A}\cdot(\nabla\times\mathbf{B}) \quad (13)$$

$$\nabla\cdot\left(\frac{\mathbf{A}}{f}\right)=\frac{f(\nabla\cdot\mathbf{A})-(\nabla f)\cdot\mathbf{A}}{f^2} \quad (14)$$

$$\nabla\cdot(\mathbf{A}+\mathbf{B})=\nabla\cdot\mathbf{A}+\nabla\cdot\mathbf{B} \quad (15)$$

In CARTESIAN COORDINATES,

$$\nabla\cdot\mathbf{x}=\nabla\cdot\mathbf{y}=\nabla\cdot\mathbf{z}=1 \quad (16)$$

$$\nabla\cdot\hat{\mathbf{x}}=\nabla\cdot\hat{\mathbf{y}}=\nabla\cdot\hat{\mathbf{z}}=0. \quad (17)$$

In SPHERICAL COORDINATES,

$$\nabla\cdot\mathbf{r}=3 \quad (18)$$

$$\nabla\cdot\hat{\mathbf{r}}=\frac{2}{\mathrm{r}} \quad (19)$$

$$\nabla\cdot[\mathbf{r}f(r)]=\frac{\partial}{\partial x}[xf(r)]+\frac{\partial}{\partial y}[yf(r)]+\frac{\partial}{\partial z}[zf(r)] \quad (20)$$

$$\frac{\partial}{\partial x}[xf(r)]=x\frac{\partial f}{\partial x}+f=x\frac{\partial f}{\partial r}\frac{\partial r}{\partial x}+f \quad (21)$$

$$\frac{\partial r}{\partial x}=\frac{\partial}{\partial x}\left(x^2+y^2+z^2\right)^{1/2}=x\left(x^2+y^2+z^2\right)^{-1/2}=\frac{x}{r} \quad (22)$$

$$\frac{\partial}{\partial x}[xf(r)]=\frac{x^2}{r}\frac{df}{dr}+f. \quad (23)$$

By symmetry,

$$\nabla\cdot[\mathbf{r}f(r)]=3f(r)+\frac{1}{r}(x^2+y^2+z^2)\frac{df}{dr}$$
$$=3f(r)+r\frac{df}{dr} \quad (24)$$

$$\nabla\cdot(\hat{\mathbf{r}}f(r))=\frac{3}{r}(r)+\frac{df}{dr} \quad (25)$$

$$\nabla\cdot(\hat{\mathbf{r}}r^n)=3r^{n-1}+(n-1)r^{n-1}=(n+2)r^{n-1}. \quad (26)$$

Vector derivative identities involving the GRADIENT include

$$\nabla(kf)=k\nabla f \quad (27)$$

$$\nabla(fg)=f\nabla g+g\nabla f \quad (28)$$

$$\nabla(\mathbf{A}\cdot\mathbf{B})=\mathbf{A}\times(\nabla\times\mathbf{B})+\mathbf{B}\times(\nabla\times\mathbf{A})+(\mathbf{A}\cdot\nabla)\mathbf{B}$$
$$+(\mathbf{B}\cdot\nabla)\mathbf{A} \quad (29)$$

$$\nabla(\mathbf{A}\cdot\nabla f)=\mathbf{A}\times(\nabla\times\nabla f)+\nabla f\times(\nabla\times\mathbf{A})+\mathbf{A}\cdot\nabla(\nabla f)$$
$$+\nabla f\cdot\nabla\mathbf{A}$$
$$=\nabla f\times(\nabla\times\mathbf{A})+\mathbf{A}\cdot\nabla(\nabla f)+\nabla f\cdot\nabla\mathbf{A} \quad (30)$$

$$\nabla\left(\frac{f}{g}\right)=\frac{g\nabla f-f\nabla g}{g^2} \quad (31)$$

$$\nabla(f+g)=\nabla f+\nabla g \quad (32)$$

$$\nabla(\mathbf{A}\cdot\mathbf{A})=2\mathbf{A}\times(\nabla\times\mathbf{A})+2(\mathbf{A}\cdot\nabla)\mathbf{A} \quad (33)$$

$$(\mathbf{A}\cdot\nabla)\mathbf{A}=\nabla\left(\tfrac{1}{2}\mathbf{A}^2\right)-\mathbf{A}\times(\nabla\times\mathbf{A}). \quad (34)$$

Vector second derivative identities include

$$\nabla^2 t\equiv\nabla\cdot(\nabla t)=\frac{\partial^2 t}{\partial x^2}+\frac{\partial^2 t}{\partial y^2}+\frac{\partial^2 t}{\partial z^2} \quad (35)$$

$$\nabla^2\mathbf{A}=\nabla(\nabla\cdot\mathbf{A})-\nabla\times(\nabla\times\mathbf{A}). \quad (36)$$

This very important second derivative is known as the LAPLACIAN.

$$\nabla\times(\nabla t)=\mathbf{0} \quad (37)$$

$$\nabla(\nabla\cdot\mathbf{A})=\nabla^2\mathbf{A}+\nabla\times(\nabla\times\mathbf{A}) \quad (38)$$

$$\nabla\cdot(\nabla\times\mathbf{A})=0 \quad (39)$$

$$\nabla\times(\nabla\times\mathbf{A})=\nabla(\nabla\cdot\mathbf{A})-\nabla^2\mathbf{A}$$
$$\nabla\times\left(\nabla^2\mathbf{A}\right)=\nabla\times[\nabla(\nabla\cdot\mathbf{A})]-\nabla\times[\nabla\times(\nabla\times\mathbf{A})]$$
$$=-\nabla\times[\nabla\times(\nabla\times\mathbf{A})]$$
$$=-\left\{\nabla[\nabla\cdot(\nabla\times\mathbf{A})]-\nabla^2(\nabla\times\mathbf{A})\right\}$$
$$=\nabla^2(\nabla\times\mathbf{A}) \quad (40)$$

$$\nabla^2(\nabla\cdot\mathbf{A})=\nabla\cdot[\nabla(\nabla\cdot\mathbf{A})]$$
$$=\nabla\cdot\left[\nabla^2\mathbf{A}+\nabla\times(\nabla\times\mathbf{A})\right]=\nabla\cdot\left(\nabla^2\mathbf{A}\right) \quad (41)$$

$$\nabla^2[\nabla\times(\nabla\times\mathbf{A})]=\nabla^2\left[\nabla(\nabla\cdot\mathbf{A})-\nabla^2\mathbf{A}\right]$$
$$=\nabla^2[\nabla(\nabla\cdot\mathbf{A})]-\nabla^4\mathbf{A} \quad (42)$$

$$\nabla\times\left[\nabla^2(\nabla\times\mathbf{A})\right]=\nabla^2[\nabla(\nabla\cdot\mathbf{A})]-\nabla^4\mathbf{A} \quad (43)$$

$$\nabla^4\mathbf{A}=-\nabla^2[\nabla\times(\nabla\times\mathbf{A})]+\nabla^2[\nabla(\nabla\cdot\mathbf{A})]$$
$$=\nabla\times\left[\nabla^2(\nabla\times\mathbf{A})\right]-\nabla^2[\nabla\times(\nabla\times\mathbf{A})]. \quad (44)$$

Identities involving combinations of vector derivatives include

$$\mathbf{A}\times(\nabla A)=\tfrac{1}{2}\nabla(\mathbf{A}\cdot\mathbf{A})-(\mathbf{A}\cdot\nabla)\mathbf{A} \quad (45)$$

$$\nabla\times(\phi\nabla\phi)=\phi\nabla\times(\nabla\phi)+(\nabla\phi)\times(\nabla\phi)=\mathbf{0} \quad (46)$$

$$(\mathbf{A}\cdot\nabla)\hat{\mathbf{r}}=\frac{\mathbf{A}-\hat{\mathbf{r}}(\mathbf{A}\cdot\hat{\mathbf{r}})}{\mathbf{r}} \quad (47)$$

$$\nabla f\cdot\mathbf{A}=\nabla\cdot(f\mathbf{A})-f(\nabla\cdot\mathbf{A}) \quad (48)$$

$$f(\nabla\cdot\mathbf{A})=\nabla\cdot(f\mathbf{A})-\mathbf{A}\nabla f, \quad (49)$$

where (48) and (49) follow from divergence rule (2).

Vector Direct Product

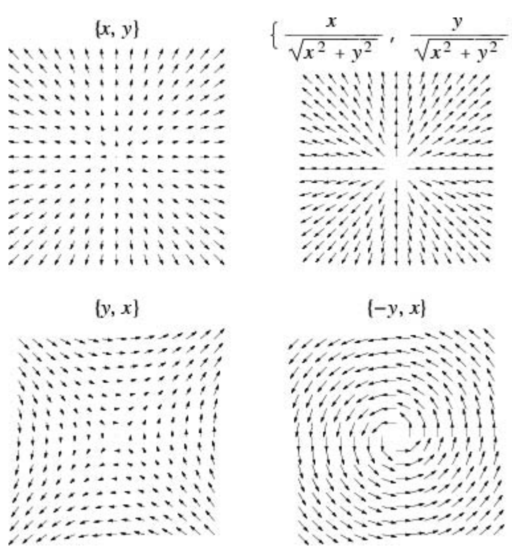
Given VECTORS $\mathbf{u}$ and $\mathbf{v}$, the vector direct product is

$$\mathbf{uv} \equiv \mathbf{u} \otimes \mathbf{v}^{\mathrm{T}}$$

where $\otimes$ is the MATRIX DIRECT PRODUCT and $\mathbf{v}^{\mathrm{T}}$ is the matrix TRANSPOSE. For 3×3 vectors

$$\mathbf{uv} = \begin{bmatrix} u_1\mathbf{v}^{\mathrm{T}} \\ u_1\mathbf{v}^{\mathrm{T}} \\ u_1\mathbf{v}^{\mathrm{T}} \end{bmatrix} = \begin{bmatrix} u_1v_1 & u_1v_2 & u_1v_3 \\ u_2v_1 & u_2v_2 & u_2v_3 \\ u_3v_1 & u_3v_2 & u_3v_3 \end{bmatrix}.$$

Note that if $\mathbf{u} = \hat{\mathbf{x}}_i$, then $u_j = \delta_{ij}$, where δ_{ij} is the KRONECKER DELTA.



See also MATRIX DIRECT PRODUCT, SHERMAN-MORRISON FORMULA, WOODBURY FORMULA

Vector Division

There is no unique solution A to the MATRIX equation $\mathbf{y} = \mathsf{A}\mathbf{x}$ unless $\mathbf{x}$ is PARALLEL to $\mathbf{y}$, in which case A is a SCALAR. Therefore, vector division is not defined.

See also MATRIX, SCALAR

Vector Field

A MAP $\mathbf{f} : \mathbb{R}^n \mapsto \mathbb{R}^n$ which assigns each $\mathbf{x}$ a VECTOR FUNCTION $\mathbf{f}(\mathbf{x})$. In French, a vector field is called "un champ." Several vector fields are illustrated above. A vector field is uniquely specified by giving its DIVERGENCE and CURL within a region and its normal component over the boundary, a result known as HELMHOLTZ'S THEOREM (Arfken 1985, p. 79).

FLOWS are generated by vector fields and vice versa. A vector field is a SECTION of its TANGENT BUNDLE.

Vector Function

A function of one or more variables whose RANGE is 3-dimensional (or, in general, n-dimensional), as compared to a SCALAR FUNCTION, whose RANGE is 1-dimensional. Vector functions are also called vector-valued functions.

See also COMPLEX FUNCTION, REAL FUNCTION, SCALAR FUNCTION, VECTOR

Vector Harmonic

VECTOR SPHERICAL HARMONIC

Vector Helmholtz Equation

HELMHOLTZ DIFFERENTIAL EQUATION

Vector Integral

The following vector integrals are related to the CURL THEOREM. If

$$\mathbf{F} \equiv \mathbf{c} \times \mathbf{P}(x, y, x), \tag{1}$$

then

$$\int_C d\mathbf{s} \times \mathbf{P} = \int_s (d\mathbf{a} \times \nabla) \times \mathbf{P} \tag{2}$$

If

$$\mathbf{F} \equiv \mathbf{c}F, \tag{3}$$

then

$$\int_C F\, ds = \int_s d\mathbf{a} \times \nabla\mathbf{F} \tag{4}$$

The following are related to the DIVERGENCE THEOREM. If

$$\mathbf{F} \equiv \mathbf{c} \times \mathbf{P}(x, y, x), \tag{5}$$

then

$$\int_V \nabla \times \mathbf{F}\, dV = \int_s d\mathbf{a} \times \mathbf{F}. \tag{6}$$

Finally, if

$$\mathbf{F} \equiv \mathbf{c}F, \tag{7}$$

then

$$\int_V \nabla F\, dV = \int_s F\, d\mathbf{a}. \tag{8}$$

See also CURL THEOREM, DIVERGENCE THEOREM, GRADIENT THEOREM, GREEN'S IDENTITIES, LINE INTEGRAL, SURFACE INTEGRAL, VECTOR DERIVATIVE, VOLUME INTEGRAL

Vector Laplacian

A vector Laplacian can be defined for a VECTOR **A** by

$$\nabla^2 \mathbf{A} = \nabla(\nabla \cdot \mathbf{A}) - \nabla \times (\nabla \times \mathbf{A}) \tag{1}$$

in vector notation. The notation ✡ is sometimes also used for a vector Laplacian (Moon and Spencer 1988, p. 3). In tensor notation, **A** is written A_μ, and the identity becomes

$$\nabla^2 A_\mu = A_{\mu;\lambda}^{;\lambda} = (g^{\lambda\kappa} A_{\mu;\lambda})_{;\kappa}$$

$$= g^{\lambda}\kappa_{;\kappa} A_{\mu;\lambda} + g^{\lambda\kappa} A_{\mu;\lambda\kappa}. \tag{2}$$

Similarly, a TENSOR Laplacian can be given by

$$\nabla^2 A_{\alpha\beta} = A_{\alpha\beta;\lambda}^{;\lambda} \tag{3}$$

Vector Multiplication

Although the multiplication of one vector by another is not uniquely defined (cf. SCALAR MULTIPLICATION, which is multiplication of a VECTOR by a SCALAR), several types of useful vector products can be defined, as summarized in the following table.

product name	symbol	result
DOT PRODUCT	$\mathbf{u} \cdot \mathbf{v}$	SCALAR
CROSS PRODUCT	$\mathbf{u} \times \mathbf{v}$	PSEUDOVECTOR
VECTOR DIRECT PRODUCT	$\mathbf{uv}$	TENSOR

Vector multiplication can also be defined for vectors taken three at a time, as summarized in the following table.

product name	symbol	result
VECTOR TRIPLE PRODUCT	$\mathbf{u} \times (\mathbf{v} \times \mathbf{w})$	VECTOR
SCALAR TRIPLE PRODUCT	$[\mathbf{u}, \mathbf{v}, \mathbf{w}]$	PSEUDOSCALAR

A number of VECTOR QUADRUPLE PRODUCTS can also be defined.

See also CROSS PRODUCT, DOT PRODUCT, SCALAR MULTIPLICATION, SCALAR TRIPLE PRODUCT, VECTOR, VECTOR ADDITION, VECTOR DIRECT PRODUCT, VECTOR QUADRUPLE PRODUCT, VECTOR TRIPLE PRODUCT, VECTOR TRIPLE PRODUCT

Vector Norm

Given an n-D VECTOR

$$\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix},$$

a vector norm $\|\mathbf{x}\|$ (sometimes written simply $\|\mathbf{x}\|$) is a NONNEGATIVE number satisfying

1. $\|\mathbf{x}\| > 0$ when $\mathbf{x} \neq 0$ and $\|\mathbf{x}\| = 0$ IFF $\mathbf{x} = 0$,
2. $\|k\mathbf{x}\| = |k|\|\mathbf{x}\|$ for any SCALAR k,
3. $\|\mathbf{x} + \mathbf{y}\| \leq \|\mathbf{x}\| + \|\mathbf{y}\|$

The vector norm $|\mathbf{x}|_p$ is implemented as `VectorNorm[`m`,` p`]` in the *Mathematica* add-on package `LinearAlgebra`MatrixMultiplication`` (which can be loaded with the command `<<LinearAlgebra``), where $1 \leq p < \infty$.

See also COMPATIBLE, L1-NORM, L2-NORM, L-INFINITY-NORM, MATRIX NORM, NATURAL NORM, NORM

Vector Ordering

If the first NONZERO component of the vector difference $\mathbf{A} - \mathbf{B}$ is > 0, then $\mathbf{A} \succ \mathbf{B}$. If the first NONZERO component of $\mathbf{A} - \mathbf{B}$ is < 0, then $\mathbf{A} \prec \mathbf{B}$.

Vector Potential

A function $\mathbf{A}$ such that

$$\mathbf{B} \equiv \nabla \times \mathbf{A}.$$

The most common use of a vector potential is the representation of a magnetic field. If a VECTOR FIELD has zero DIVERGENCE, it may be represented by a vector potential.

See also DIVERGENCE, HELMHOLTZ'S THEOREM, POTENTIAL FUNCTION, SOLENOIDAL FIELD, VECTOR FIELD

Vector Product

CROSS PRODUCT, SCALAR TRIPLE PRODUCT, VECTOR MULTIPLICATION, VECTOR DIRECT PRODUCT, VECTOR QUADRUPLE PRODUCT, VECTOR TRIPLE PRODUCT

Vector Quadruple Product

There are a number of algebraic identities involving sets of four VECTORS. LAGRANGE'S IDENTITY is given by

$$(\mathbf{A} \times \mathbf{B}) \cdot (\mathbf{C} \times \mathbf{D}) = (\mathbf{A} \cdot \mathbf{C})(\mathbf{A} \cdot \mathbf{D}) - (\mathbf{A} \cdot \mathbf{D})(\mathbf{B} \cdot \mathbf{C}). \quad (1)$$

A number of other useful identities include

$$(\mathbf{A} \times \mathbf{B})^2 \equiv (\mathbf{A} \times \mathbf{B}) \cdot (\mathbf{A} \times \mathbf{B})$$

$$= (\mathbf{A} \cdot \mathbf{A})(\mathbf{B} \cdot \mathbf{B}) - (\mathbf{A} \cdot \mathbf{B})(\mathbf{B} \cdot \mathbf{A})$$

$$= \mathbf{A}^2\mathbf{B}^2 - (\mathbf{A} \cdot \mathbf{B})^2 \quad (2)$$

$$\mathbf{A} \times (\mathbf{B} \times (\mathbf{C} \times \mathbf{D})) = \mathbf{B}(\mathbf{A} \cdot (\mathbf{C} \times \mathbf{D})) - (\mathbf{A} \cdot \mathbf{B})(\mathbf{C} \times \mathbf{D}) \quad (3)$$

$$(\mathbf{A} \times \mathbf{B}) \times (\mathbf{C} \times \mathbf{D}) = (\mathbf{C} \times \mathbf{D}) \times (\mathbf{B} \times \mathbf{A}) \quad (4)$$

$$= [\mathbf{A}, \mathbf{B}, \mathbf{D}]\mathbf{C} - [\mathbf{A}, \mathbf{B}, \mathbf{C}]\mathbf{D} \quad (5)$$

$$[\mathbf{C}, \mathbf{D}, \mathbf{A}]\mathbf{B} - [\mathbf{C}, \mathbf{D}, \mathbf{B}]\mathbf{A}, \quad (6)$$

where $[\mathbf{A}, \mathbf{B}, \mathbf{C}]$ denotes the SCALAR TRIPLE PRODUCT.

See also LAGRANGE'S IDENTITY, SCALAR TRIPLE PRODUCT, VECTOR MULTIPLICATION, VECTOR TRIPLE PRODUCT

Vector Space

A vector space over $\mathbb{R}^n$ is a set of VECTORS for which any VECTORS $\mathbf{X}$, $\mathbf{Y}$, and $\mathbf{Z} \in \mathbb{R}^n$ and any SCALARS r, $s \in \mathbb{R}$ have the following properties:

1. COMMUTATIVITY:
$$\mathbf{X} + \mathbf{Y} = \mathbf{Y} + \mathbf{X}.$$
2. ASSOCIATIVITY of VECTOR ADDITION:
$$(\mathbf{X} + \mathbf{Y}) + \mathbf{Z} = \mathbf{X} + (\mathbf{Y} + \mathbf{Z}).$$
3. Additive identity: For all $\mathbf{X}$,
$$\mathbf{0} + \mathbf{X} = \mathbf{X} + \mathbf{0} = \mathbf{X}.$$
4. Existence of additive inverse: For any $\mathbf{X}$, there exists a $-\mathbf{X}$ such that
$$\mathbf{X} + (-\mathbf{X}) = \mathbf{0}.$$
5. ASSOCIATIVITY of scalar multiplication:
$$r(s\mathbf{X}) = (rs)\mathbf{X}.$$
6. DISTRIBUTIVITY of scalar sums:
$$(r + s)\mathbf{X} = r\mathbf{X} + s\mathbf{X}.$$
7. DISTRIBUTIVITY of vector sums:
$$r(\mathbf{X} + \mathbf{Y}) = r\mathbf{X} + r\mathbf{Y}.$$
8. Scalar multiplication identity:
$$1\mathbf{X} = \mathbf{X}.$$

Let V be a vector space of dimension n over the FIELD of q elements (where q is necessarily a power of a prime number). Then the number of distinct nonsingular linear operators on V is

$$M(n,q) = (q^n - q^0)(q^n - q^1)(q^n - q^2)\cdots(q^n - q^{n-1}) \quad (1)$$

and the number of distinct k-dimensional subspaces of V is

$$S(k,n,q) = \frac{(q^n - q^0)(q^n - q^1)(q^n - q^2)\cdots(q^n - q^{k-1})}{M(k,q)} \quad (2)$$

$$= \frac{(q^n - 1)(q^{n-1} - 1)(q^{n-2} - 1)\cdots(q^{n-k+1} - 1)}{(q^k - 1)(q^{k-1} - 1)(q^{k-2} - 1)\cdots(q - 1)}. \quad (3)$$

A consequence of the AXIOM OF CHOICE is that every vector space has a BASIS.

A MODULE is abstractly similar to a vector space, but it uses a RING to define COEFFICIENTS instead of the FIELD used for vector spaces. MODULES have COEFFICIENTS in much more general algebraic objects.

Vector Spherical Harmonic

The SPHERICAL HARMONICS can be generalized to vector spherical harmonics by looking for a SCALAR FUNCTION ψ and a constant VECTOR $\mathbf{c}$ such that

$$\mathbf{M} \equiv \nabla \times (\mathbf{c}\psi) = \psi(\nabla \times \mathbf{c}) + (\nabla\psi) \times \mathbf{c}$$

$$= (\nabla\psi) \times \mathbf{c} = -\mathbf{c} \times \nabla\psi, \tag{1}$$

so

$$\nabla \cdot \mathbf{M} = 0. \tag{2}$$

Now use the vector identities

$$\nabla^2\mathbf{M} = \nabla^2(\nabla \times \mathbf{M}) = \nabla \times (\nabla^2\mathbf{M})$$

$$= \nabla(\nabla^2\mathbf{c}\psi) = \nabla \times (\mathbf{c}\nabla^2\psi) \tag{3}$$

$$k^2\mathbf{M} = k^2\nabla \times (\mathbf{c}\psi) = \nabla \times (\mathbf{c}\nabla^2\psi) \tag{4}$$

so

$$\nabla^2\mathbf{M} + k^2\mathbf{M} = \nabla \times [\mathbf{c}(\nabla^2\psi + \kappa^2\psi)], \tag{5}$$

and $\mathbf{M}$ satisfies the vector HELMHOLTZ DIFFERENTIAL EQUATION if ψ satisfies the scalar HELMHOLTZ DIFFERENTIAL EQUATION

$$\nabla^2\psi + k^2\psi = 0. \tag{6}$$

Construct another vector function

$$\mathbf{N} = \frac{\nabla \times \mathbf{M}}{k}, \tag{7}$$

which also satisfies the vector HELMHOLTZ DIFFERENTIAL EQUATION since

$$\nabla^2\mathbf{N} = \frac{1}{k}\nabla^2(\nabla \times \mathbf{M}) = \frac{1}{k}\nabla \times (\nabla^2\mathbf{M})$$

$$= \frac{1}{k}\nabla \times (-k^2\mathbf{M}) = -k\nabla \times \mathbf{M} = -k^2\mathbf{N}, \tag{8}$$

which gives

$$\nabla^2\mathbf{N} + k^2\mathbf{N} = 0. \tag{9}$$

We have the additional identity

$$\nabla \times \mathbf{N} = \frac{1}{k}\nabla \times (\nabla \times \mathbf{M}) = \frac{1}{k}\nabla \times (\nabla \cdot \mathbf{M})$$

$$= \frac{1}{k}\nabla^2\mathbf{M} - \frac{1}{k}\nabla^2\mathbf{M} = \frac{-\nabla^2\mathbf{M}}{k} = k\mathbf{M}. \tag{10}$$

In this formalism, ψ is called the generating function and $\mathbf{c}$ is called the PILOT VECTOR. The choice of generating function is determined by the symmetry of the scalar equation, i.e., it is chosen to solve the desired scalar differential equation. If $\mathbf{M}$ is taken as

$$\mathbf{M} = \nabla \times (\mathbf{r}\psi), \tag{11}$$

where $\mathbf{r}$ is the radius vector, then $\mathbf{M}$ is a solution to the vector wave equation in spherical coordinates. If we want vector solutions which are tangential to the radius vector,

$$\mathbf{M} \cdot \mathbf{r} = \mathbf{r} \cdot (\nabla\psi \times \mathbf{c}) = (\nabla\psi)(\mathbf{c} \times \mathbf{r}) = 0, \tag{12}$$

so

$$\mathbf{c} \times \mathbf{r} = 0 \tag{13}$$

and we may take

$$\mathbf{c} = \mathbf{r} \tag{14}$$

(Arfken 1985, pp. 707–711; Bohren and Huffman 1983, p. 88).

A number of conventions are in use. Hill (1954) defines

$$V_l^m \equiv -\sqrt{\frac{l+1}{2l+1}}\,Y_l^m\hat{\mathbf{r}} + \frac{1}{\sqrt{(l+1)(2l+1)}}\frac{\partial Y_l^m}{\partial\theta}\hat{\boldsymbol{\theta}}$$

$$+iM\sqrt{(l+1)(2l+1)}\sin\theta Y_l^m\hat{\boldsymbol{\phi}} \tag{15}$$

$$W_l^m = \sqrt{\frac{l}{2l+1}}\,Y_l^m\hat{\mathbf{r}} + \frac{1}{\sqrt{l(2l+1)}}\frac{\partial Y_l^m}{\partial\theta}\hat{\boldsymbol{\theta}}$$

$$+\frac{iM}{\sqrt{l(2l+1)}\sin\theta}Y_l^m\hat{\boldsymbol{\phi}} \tag{16}$$

$$X_l^m = -\frac{M}{\sqrt{l(l+1)}\sin\theta}Y_l^m\hat{\boldsymbol{\theta}} - \frac{i}{\sqrt{l(l+1)}}\frac{\partial Y_l^m}{\partial\theta}\hat{\boldsymbol{\phi}} \tag{17}$$

Morse and Feshbach (1953) define vector harmonics called $\mathbf{B}$, $\mathbf{C}$, and $\mathbf{P}$ using rather complicated expressions.

Vector Transformation Law

The set of n quantities v_j are components of an n-D VECTOR $\mathbf{v}$ IFF, under ROTATION,

$$v_i' = a_{ij} v_j$$

for $i = 1, 2, ..., n$. The DIRECTION COSINES between x_i' and x_j are

$$a_{ij} \equiv \frac{\partial x_i'}{\partial x_j} = \frac{\partial x_j}{\partial x_i'}.$$

They satisfy the orthogonality condition

$$a_{ij} a_{ik} = \frac{\partial x_j}{\partial x_i'} \frac{\partial x_i'}{\partial x_k} = \frac{\partial x_j}{\partial x_k} = \delta_{jk},$$

where δ_{jk} is the KRONECKER DELTA.

See also TENSOR, VECTOR

Vector Triple Product

The vector triple product identity is also known as the BAC-CAB IDENTITY, and can be written in the form

$$\mathbf{A} \times (\mathbf{B} \times \mathbf{C}) = \mathbf{B}(\mathbf{A} \cdot \mathbf{C}) - \mathbf{C}(\mathbf{A} \cdot \mathbf{B}) \quad (1)$$

$$(\mathbf{A} \times \mathbf{B}) \times \mathbf{C} = -\mathbf{C} \times (\mathbf{A} \times \mathbf{B})$$

$$= -\mathbf{A}(\mathbf{B} \cdot \mathbf{C}) + \mathbf{B}(\mathbf{A} \cdot \mathbf{C}) \quad (2)$$

Vector-Valued Function

VECTOR FUNCTION

Vee

The symbol $\vee$ variously means "disjunction" (i.e., OR in LOGIC) or "join" (for a LATTICE).

See also OR, WEDGE

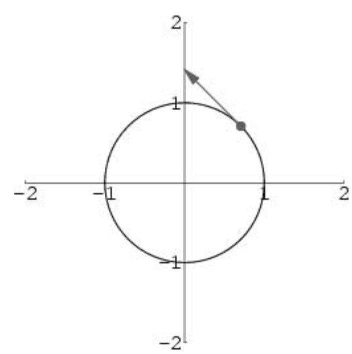
Velocity

$$\mathbf{v} \equiv \frac{d\mathbf{r}}{dt},$$

where $\mathbf{r}$ is the POSITION VECTOR and d/dt is the derivative with respect to time. Expressed in terms of the ARC LENGTH,

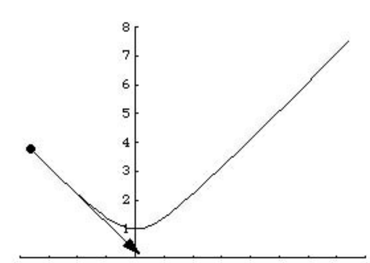
$$\mathbf{v} = \frac{ds}{dt} \hat{\mathbf{T}},$$

where $\hat{\mathbf{T}}$ is the unit TANGENT VECTOR, so the SPEED (which is the magnitude of the velocity) is



$$v \equiv |\mathbf{v}| = \frac{ds}{dt} = |\mathbf{r}'(t)|.$$

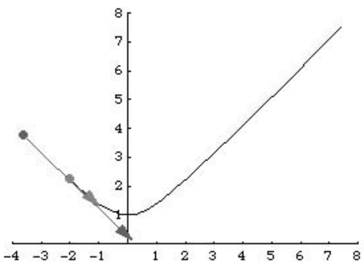
See also ANGULAR VELOCITY, POSITION VECTOR, SPEED



Velocity Vector

The idea of a velocity vector comes from classical physics. By representing the position and motion of a single particle using vectors, the equations for motion are simpler and more intuitive. Suppose the position of a particle at time t is given by the position vector $s(t) = (s_1(t), s_2(t), s_3(t))$. Then the velocity vector $v(t)$ is the derivative of the position,

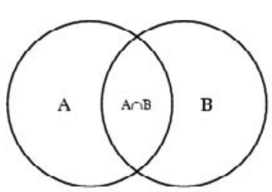
$$v = \frac{ds}{dt} = \left(\frac{ds_1}{dt}, \frac{ds_2}{dt}, \frac{ds_3}{dt} \right).$$

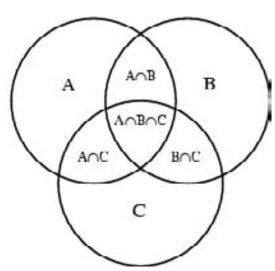


For example, suppose a particle is confined to the plane and its position is given by $s = (\cos t, \sin t)$. Then it travels along the unit circle at constant speed. Its velocity vector is $v = (-\sin t, \cos t)$. In a diagram, it makes sense to translate the velocity vector so it originates at s. In particular, it is drawn as an arrow from s to $s + v$.

Another example is a particle traveling along a HYPERBOLA specified parametrically by $s(t) =$

(sinh(t), cosh(t)). Its velocity vector is then given by $v = (\cosh(t), \sinh(t))$, illustrated above.





Travel down the same path, but using a different function is called a REPARAMETRIZATION, and the CHAIN RULE describes the change in velocity. For example, the HYPERBOLA can also be parametrized by $r(t) = \left(t, \sqrt{1+t^2}\right)$. Note that $r(\sinh(t)) = s(t)$, and by the CHAIN RULE, $dr/dt(\cosh t) = ds/dt$.

Note that the set of possible velocity vectors forms a VECTOR SPACE. If r and s are two paths through the origin, then so is $r+s$ and the velocity vector of this path is $dr/dt + ds/dt$. Similarly, if α is a scalar, then the path αs has velocity vector αv. It makes sense to distinguish the velocity vectors at different points. In physics, the set of all velocity vectors gives all possible combinations of position and momentum, and is called phase space. In mathematics, the velocity vectors form the tangent space, and the collection of tangent spaces forms the TANGENT BUNDLE.

See also CALCULUS, COORDINATE CHART, DIRECTIONAL DERIVATIVE, EUCLIDEAN SPACE, JACOBIAN, MANIFOLD, TANGENT BUNDLE, TANGENT SPACE, TANGENT VECTOR, VECTOR FIELD, VECTOR SPACE

Venn Diagram

A schematic diagram used in LOGIC theory to depict collections of sets and represent their relationships.

The Venn diagrams on two and three sets are illustrated above. The order-two diagram (left) consists of two intersecting circles, producing a total of four regions, A, B, $A \cap B$, and $\varnothing$ (the EMPTY SET, represented by none of the regions occupied). Here, $A \cap B$ denotes the INTERSECTION of sets A and B.

The order-three diagram (right) consists of three symmetrically placed mutually intersecting CIRCLES comprising a total of eight regions. The regions labeled A, B, and C consist of members which are only in one set and no others, the three regions labelled $A \cap B$, $A \cap C$, and $B \cap C$ consist of members which are in two sets but not the third, the region $A \cap B \cap C$ consists of members which are simultaneously in all three, and no regions occupied represents $\varnothing$.

In general, an order-n Venn diagram is a collection of n simple closed curves in the PLANE such that

1. The curves partition the PLANE into 2^n connected regions, and
2. Each SUBSET S of $\{1, 2, \ldots, n\}$ corresponds to a unique region formed by the intersection of the interiors of the curves in S (Ruskey).

Since there are $\binom{n}{k}$ (the BINOMIAL COEFFICIENT) ways to pick k members from a total of n, the number of regions in an order n Venn diagram is

$$N = \sum_{k=0}^{n} \binom{n}{k} = 2^n,$$

(where the region outside the diagram is included in the count).

The region of INTERSECTION of the three CIRCLES $A \cap B \cap C$ in the order three Venn diagram in the special case of the center of each being located at the INTERSECTION of the other two is a geometric shape known as a REULEAUX TRIANGLE.

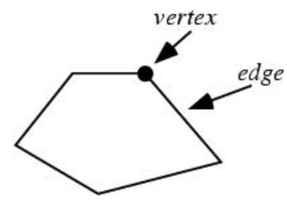
Vertex (Graph)

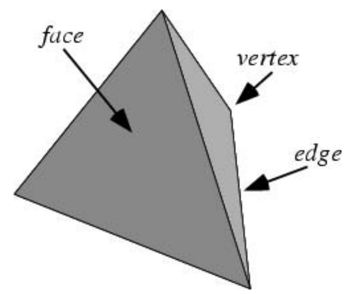


A point of a GRAPH, also called a NODE.

See also EDGE (GRAPH), NULL GRAPH, TAIT COLORING, TAIT CYCLE, TAIT'S HAMILTONIAN GRAPH CONJECTURE, VERTEX (POLYGON)

Vertex (Parabola)

For a PARABOLA oriented vertically and opening upwards, the vertex is the point where the curve reaches a minimum.

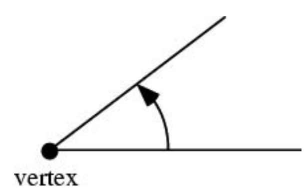


Vertex (Polygon)

A point at which two EDGES of a POLYGON meet.

See also PRINCIPAL VERTEX, VERTEX (GRAPH), VERTEX (POLYHEDRON)

Vertex (Polyhedron)

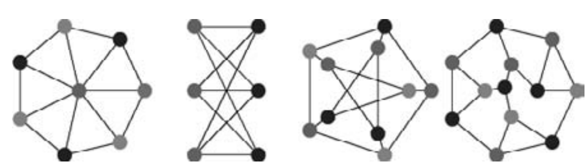


A point at which three of more EDGES of a POLYHEDRON meet. The concept can also be generalized to a POLYTOPE.

See also VERTEX (GRAPH), VERTEX (POLYGON)

Vertex (Polytope)

The vertex of a POLYTOPE is a point where edges of the POLYTOPE meet.



Vertex Angle

The point about which an ANGLE is measured is called the angle's vertex, and the angle associated with a given vertex is called the vertex angle.

See also ANGLE

Vertex Coloring

A vertex coloring is an assignment of labels or colors to each vertex of a graph such that no edge connects

two identically colored vertices. The most common type of vertex coloring seeks to minimize the number of colors for a given graph. BRELAZ'S HEURISTIC ALGORITHM can be used to find a good, but not necessarily minimal, vertex coloring of a GRAPH. Finding a minimal coloring can be done using brute-force search (Christofides 1971; Wilf 1984; Skiena 1990, p. 214). The minimum number of colors which with the vertices of a graph G may be colored is called the CHROMATIC NUMBER, denoted $\chi(G)$.

The only one-colorable graphs are EMPTY GRAPHS, and two-colorable graphs are exactly BIPARTITE GRAPHS. The FOUR-COLOR THEOREM establishes that all PLANAR GRAPHS are 4-colorable.

See also BRELAZ'S HEURISTIC ALGORITHM, BROOKS' THEOREM, CHROMATIC NUMBER, CHROMATIC POLYNOMIAL, COLORING, EDGE CHROMATIC NUMBER, FOUR-COLOR THEOREM, k-COLORING

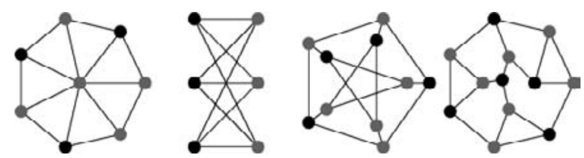
Vertex Connectivity

The minimum number of nodes $\kappa(G)$ whose deletion from a GRAPH G disconnects it. Vertex connectivity is sometimes called "point connectivity" or simply "connectivity".

Let $\lambda(G)$ be the EDGE CONNECTIVITY of a graph G and $\delta(G)$ its minimum degree, then for any graph,

$$\kappa(G) \leq \lambda(G) \leq \delta(G)$$

(Whitney 1932, Harary 1994, p. 43).



The vertex connectivity of a graph can be determined with the command VertexConnectivity[g] in the *Mathematica* add-on package DiscreteMath`Combinatorica` (which can be loaded with the command << DiscreteMath`).

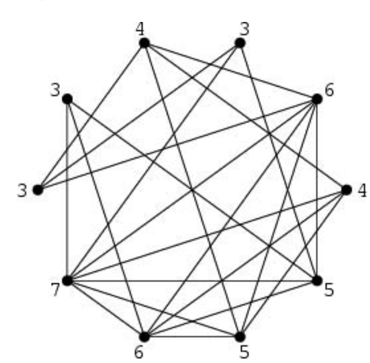
Whitney, H. "Congruent Graphs and the Connectivity of Graphs." *Amer. J. Math.* **54**, 150–168, 1932.

Vertex Cover

Let S be a collection of subsets of a finite set X. The smallest subset Y of X that meets every member of S is called the vertex cover, or hitting set. However, some authors call any such set a vertex cover, and then refer to the minimum vertex cover (Skiena 1990, p. 218). Finding the hitting set is an NP-COMPLETE PROBLEM.



Vertex covers, indicated with red coloring, are shown above for a number of graphs. In a COMPLETE k-PARTITE GRAPH, and vertex cover contains vertices from at least $k-1$ stages. The minimum vertex cover of a GRAPH can be computed using MinimumVertexCover[g] in the *Mathematica* add-on package DiscreteMath`Combinatorica` (which can be loaded with the command << DiscreteMath`).

Vertex Degree

The degree of a VERTEX v of a GRAPH G is the number of EDGES which touch v. The vertex degrees are illustrated above for a random graph. The vertex

degree is also called the local degree or valency. The ordered list of vertex degrees in a given graph is called its DEGREE SEQUENCE. A list of vertex degrees of a graph can be given by `VertexDegrees[g]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).
The minimum vertex degree in a GRAPH G is denoted $\delta(G)$, and the maximum degree is denoted $\Delta(G)$ (Skiena 1990, p. 157).

The VERTEX degree of a point v in a GRAPH, denoted $\rho(v)$, satisfies

$$\sum_{i=1}^{n} \rho(v_i) = 2E,$$

where E is the total number of EDGES.

DIRECTED GRAPHS have two types of degrees, known as the INDEGREE and the OUTDEGREE.

See also DEGREE SEQUENCE, DIRECTED GRAPH, EDGE (GRAPH), EVEN NODE, GRAPH, INDEGREE, LOCAL DEGREE, ODD NODE, OUTDEGREE, PLANTED TREE, VERTEX (GRAPH)

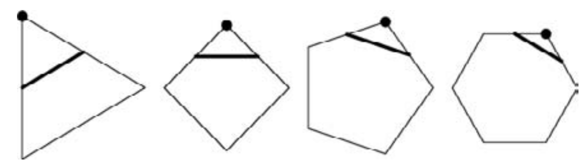
Vertex Enumeration

A CONVEX POLYHEDRON is defined as the set of solutions to a system of linear inequalities



$$\mathsf{m}\mathbf{x} \leq \mathbf{b},$$

where m is a REAL $s \times d$ MATRIX and $\mathbf{b}$ is a REAL s-VECTOR. Given m and $\mathbf{b}$, vertex enumeration is the determination of the polyhedron's VERTICES.

Vertex Figure

The vertex figure at a vertex V of a POLYGON is the line segment joining the MIDPOINTS of the two adjacent sides meeting at V. For a regular n-gon with side length a, the length v of the vertex figure is

$$v = a \cos\left(\frac{\pi}{n}\right)$$

The vertex figure at a vertex V of a POLYHEDRON is the polygon whose sides are the vertex figures of the faces surrounding V. The faces that join at a VERTEX form a SOLID ANGLE whose section by the plane is the vertex figure.

Vertex Scheme

If K is a SIMPLICIAL COMPLEX, let V be the VERTEX SET of K. Furthermore, let $\mathfrak{K}$ be the collection of all subsets $\{a_0, \ldots, a_n\}$ of V such that the vertices a_0, ..., a_n span a SIMPLEX of K. Then the collection $\mathfrak{K}$ is called the vertex scheme of K (Munkres 1993, p. 15).

See also GEOMETRIC REALIZATION, VERTEX SET

References
Munkres, J. R. *Elements of Algebraic Topology.* Perseus Press, 1993.

Vertex Set

The vertex set of a GRAPH is simply a set of all vertices of the graph.

The vertex set V of an ABSTRACT SIMPLICIAL COMPLEX S is the union of one-point elements of S (Munkres 1993, p. 15).

Vertex-Transitive Graph

A GRAPH such that every pair of vertices is equivalent under some element of its automorphism group. Every nontrivial graph that is EDGE-TRANSITIVE but not vertex-transitive contains at least 20 vertices (Skiena 1990, p. 186). The smallest known CUBIC GRAPH that is EDGE- but not vertex-transitive is the GRAY GRAPH.

Vertically Convex Polyomino

COLUMN-CONVEX POLYOMINO

Veryprime

A POSITIVE INTEGER n is a veryprime IFF all primes $p \leq \sqrt{n}$ satisfy

$$\begin{cases} |2[n \pmod{p}] - p| \leq 1 & \text{very strong} \\ |2[n \pmod{p}] - p| \leq \sqrt{p} & \text{strong} \\ |2[n \pmod{p}] - p| \leq p/2 & \text{weak} \end{cases}$$

The weak veryprimes are then 2, 3, 5, 7, 11, 13, 17, 19, 23, 37, 43, 47, 53, 67, 73, 103, 107, 137, 157, 173, 227, 347, 487, 773, ... (Sloane's A050264), the strong veryprimes are 2, 3, 5, 7, 11, 13, 17, 19, 23, 37, 43, 47, 53, 67, 73, 137, 227, ..., and the very strong veryprimes are 2, 3, 5, 7, 11, 13, 17, 19, 23, 37, 43, 47, 53,

67, 73, 137, ..., with no others in the first 100,000 primes.

Vesica Piscis

LENS

Vibration Problem

Solution of a system of second-order homogeneous ordinary differential equations with constant COEFFICIENTS OF THE FORM

$$\frac{d^2\mathbf{x}}{dt^2} + \mathsf{b}\mathbf{x} = 0,$$

where b is a POSITIVE DEFINITE MATRIX. To solve the vibration problem,

1. Solve the CHARACTERISTIC EQUATION of b to get EIGENVALUES λ_1, ..., λ_n. Define $\omega_i \equiv \sqrt{\lambda_i}$.
2. Compute the corresponding EIGENVECTORS $\mathbf{e}_1$, ..., $\mathbf{e}_n$.
3. The normal modes of oscillation are given by $\mathbf{x}_1 = A_1 \sin(\omega_1 t + \alpha_1)\mathbf{e}_1$, ..., $\mathbf{x}_n = A_n \sin(\omega_n t + \alpha_n)\mathbf{e}_n$, where A_1, ..., A_n and α_1, ..., α_n are arbitrary constants.
4. The general solution is $\mathbf{x} = \Sigma_{i=1}^n \mathbf{x}_i$.

Vickrey Auction

An AUCTION in which the highest bidder wins but pays only the second-highest bid. This variation over the normal bidding procedure is supposed to encourage bidders to bid the largest amount they are willing to pay.

See also AUCTION

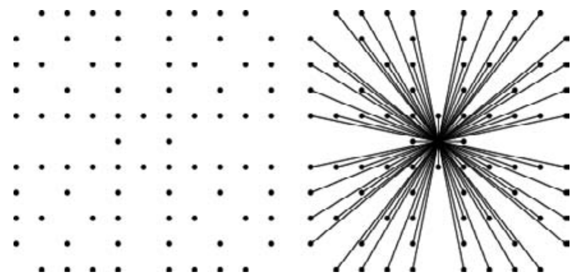
Virtual Group

GROUPOID

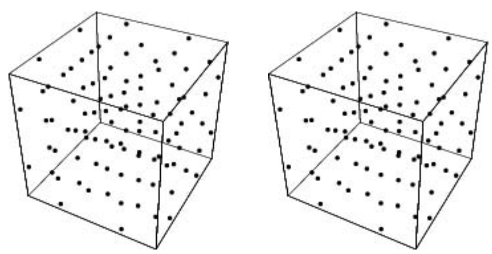
Visibility

VISIBLE POINT



Visibility Graph

Let S be a set of simple polygonal obstacles in the plane, then the nodes of the visibility graph of S are just the vertices of S, and there is an edge (called a visibility edge) between vertices v and w if these vertices are mutually visible.



References

de Berg, M.; van Kreveld, M.; Overmans, M.; and Schwarzkopf, O. "Visibility Graphs: Finding the Shortest Route." Ch. 15 in *Computational Geometry: Algorithms and Applications, 2nd rev. ed.* Berlin: Springer-Verlag, pp. 307–317, 2000.

Visible Point

Two LATTICE POINTS (x, y) and (x', y') are mutually visible if the line segment joining them contains no further LATTICE POINTS. This corresponds to the requirement that $(x'-x, y'-y)=1$, where (m, n) denotes the GREATEST COMMON DIVISOR. The plots above show the first few points visible from the ORIGIN.

If a LATTICE POINT is selected at random in 2-D, the probability that it is visible from the origin is $6/\pi^2$. This is also the probability that two INTEGERS picked at random are RELATIVELY PRIME. If a LATTICE POINT is picked at random in n-D, the probability that it is visible from the ORIGIN is $1/\zeta(n)$, where $\zeta(n)$ is the RIEMANN ZETA FUNCTION.

An invisible figure is a POLYGON all of whose corners are invisible. There are invisible sets of every finite shape. The lower left-hand corner of the invisible squares with smallest x coordinate of AREAS 2 and 3 are (14, 20) and (104, 6200).

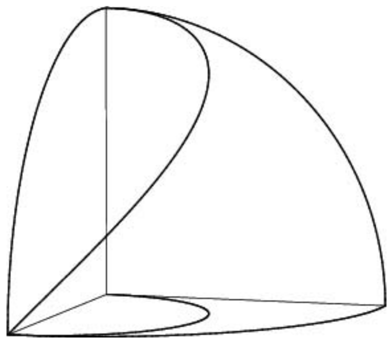
Vitali's Convergence Theorem



Let $fn(z)$ be a sequence of functions, each regular in a region D, let $|fn(z)|\leq M$ for every n and z in D, and let $fn(z)$ tend to a limit as $n\to\infty$ at a set of points having a LIMIT POINT inside D. Then $fn(z)$ tends uniformly to a limit in any region bounded by a contour interior to D, the limit therefore being an analytic function of z.

Viviani's Theorem

For a point P inside an EQUILATERAL TRIANGLE ΔABC, the sum of the perpendiculars p_i from P to the sides of the TRIANGLE is equal to the ALTITUDE h. This result is simply proved as follows,

$$\Delta ABC=\Delta PBC+\Delta PCA+\Delta PAB. \quad (1)$$

With s the side length,

$$\tfrac{1}{2}sh=\tfrac{1}{2}sp_a+\tfrac{1}{2}sp_b+\tfrac{1}{2}sp_c, \quad (2)$$

so

$$h=p_a+p_b+p_c. \quad (3)$$

See also ALTITUDE, EQUILATERAL TRIANGLE

Vizing Conjecture

Let $\gamma(G)$ denote the DOMINATION NUMBER of a SIMPLE GRAPH G. Then Vizing (1963) conjectured that

$$\gamma(G)\gamma(H)\leq\gamma(G\times H),$$

where $G\times H$ is the GRAPH PRODUCT. While the full conjecture remains open, Clark and Suen (2000) have proved the looser result

$$\gamma(G)\gamma(H)\leq 2\gamma(G\times H).$$

See also DOMINATION NUMBER

Volume

The volume of a solid body is the amount of "space" it occupies. Volume has units of LENGTH cubed (i.e., cm^3, m^3, in^3, etc.) For example, the volume of a box (RECTANGULAR PARALLELEPIPED) of LENGTH L, WIDTH W, and HEIGHT H is given by

$$V = L \times W \times H.$$

The volume can also be computed for irregularly-shaped and curved solids such as the CYLINDER and CUBE. The volume of a SURFACE OF REVOLUTION is particularly simple to compute due to its symmetry.

The following table gives volumes for some common SURFACES. Here r denotes the RADIUS, h the height, and A the base AREA, and, in the case of the TORUS, R the distance from the torus center to the center of the tube (Beyer 1987).

SURFACE	Volume
CONE	$\frac{1}{3}\pi r^2 h$
CONICAL FRUSTUM	$\frac{1}{3}\pi h(R_1^2 + R_2^2 + R_1 R_2)$
CUBE	a^3
CYLINDER	$\pi r^2 h$
ELLIPSOID	$\frac{4}{3}\pi abc$
OBLATE SPHEROID	$\frac{4}{3}\pi a^2 b$
PROLATE SPHEROID	$\frac{4}{3}\pi ab^2$
PYRAMID	$\frac{1}{3}Ah$
PYRAMIDAL FRUSTUM	$\frac{1}{3}h(A_1 + A_2 + \sqrt{A_1 A_2})$
SPHERE	$\frac{4}{3}\pi r^3$
SPHERICAL CAP	$\frac{1}{3}\pi h^2(3r - h)$
SPHERICAL SECTOR	$\frac{2}{3}\pi r^2 h$
SPHERICAL SEGMENT	$\frac{1}{6}\pi h(3a^2 + 3b^2 + h^2)$
TORUS	$2\pi^2 R r^2$

Even simple SURFACES can display surprisingly counterintuitive properties. For instance, the SURFACE OF REVOLUTION of $y = 1/x$ around the x-AXIS for $x \geq 1$ is called GABRIEL'S HORN, and has finite volume, but infinite SURFACE AREA.

The generalization of volume to n DIMENSIONS for $n \geq 4$ is known as CONTENT.

See also ARC LENGTH, AREA, BELLOWS CONJECTURE, CONTENT, HEIGHT, LENGTH (SIZE), SURFACE AREA, SURFACE OF REVOLUTION, VOLUME ELEMENT, VOLUME THEOREM, WIDTH (SIZE)

Beyer, W. H. *CRC Standard Mathematical Tables, 28th ed.* Boca Raton, FL: CRC Press, pp. 127–132, 1987.

Volume Element

A volume element is the differential element dV whose VOLUME INTEGRAL over some range in a given coordinate system gives the VOLUME of a solid,

$$V = \iiint_G dx\, dy\, dz. \tag{1}$$

In $\mathbb{R}^n$, the volume of the infinitesimal n-HYPERCUBE bounded by dx_1, ..., dx_n has volume given by the WEDGE PRODUCT

$$dV = dx_1 \wedge \ldots \wedge dx_n \tag{2}$$

(Gray 1997).

The use of the antisymmetric WEDGE PRODUCT instead of the symmetric product $dx_1 \ldots dx_n$ is a technical refinement often omitted in informal usage. Dropping the wedges, the volume element for CURVILINEAR COORDINATES in $\mathbb{R}^3$ is given by

$$dV = |(h_1 \hat{\mathbf{u}}_1\, du_1) \cdot (h_2 \hat{\mathbf{u}}_2\, du_2) \times (h_3 \hat{\mathbf{u}}_3\, du_3)| \tag{3}$$

$$= h_1 h_2 h_3\, du_1\, du_2\, du_3 \tag{4}$$

$$= \left| \frac{\partial \mathbf{r}}{\partial u_1} \cdot \frac{\partial \mathbf{r}}{\partial u_2} \times \frac{\partial \mathbf{r}}{\partial u_3} \right| du_1\, du_2\, du_3 \tag{5}$$

$$= \begin{vmatrix} \frac{\partial x}{\partial u_1} & \frac{\partial x}{\partial u_2} & \frac{\partial x}{\partial u_3} \\ \frac{\partial y}{\partial u_1} & \frac{\partial y}{\partial u_2} & \frac{\partial y}{\partial u_3} \\ \frac{\partial z}{\partial u_1} & \frac{\partial z}{\partial u_2} & \frac{\partial z}{\partial u_3} \end{vmatrix} du_1\, du_2\, du_3 \qquad (6)$$

$$= \left| \frac{\partial(x,y,z)}{\partial(u_1,u_2,u_3)} \right| du_1\, du_2\, du_3, \qquad (7)$$

where the latter is the JACOBIAN and the h_i are SCALE FACTORS.

von Dyck's Theorem

Let a GROUP G have a presentation

$$G = (x_1, \ldots, x_n | r_j(x_1, \ldots, x_n), j \in J)$$

so that $G = F/R$, where F is the FREE GROUP with basis $\{x_1, \ldots, x_n\}$ and R is the NORMAL SUBGROUP generated by the r_j. If H is a GROUP with $H = \langle y_1, \ldots, y_n \rangle$ and if $r_j(y_1, \ldots, y_n) = 1$ for all j, then there is a surjective homomorphism $G \to H$ with $x_i \mapsto y_i$ for all i.

von Neumann-Bernays-Gödel Set Theory

This entry contributed by MATTHEW SZUDZIK

von Neumann-Bernays-Gödel set theory (abbreviated "NBG") is a version of SET THEORY which was designed to give the same results as ZERMELO-FRAENKEL SET THEORY, but in a more logically elegant fashion. It can be viewed as a conservative extension of ZERMELO-FRAENKEL SET THEORY in the sense that a statement about sets is provable in NBG if and only if it is provable in ZERMELO-FRAENKEL SET THEORY.

ZERMELO-FRAENKEL SET THEORY is not finitely axiomatized. For example, the AXIOM OF REPLACEMENT is not really a single axiom, but an infinite family of axioms, since it is preceded by the stipulation that it is true "for any set-theoretic formula $A(u,v)$." Montague (1961) proved that ZERMELO-FRAENKEL SET THEORY is not finitely axiomatizable, i.e., there is no finite set of axioms which is logically equivalent to the infinite set of ZERMELO-FRAENKEL AXIOMS. In contrast, von Neumann-Bernays-Gödel set theory has only finitely many axioms, and this was the main motivation in its construction. This was accomplished by extending the language of ZERMELO-FRAENKEL SET THEORY to be capable of talking about CLASSES.

von Staudt Theorem

VON STAUDT-CLAUSEN THEOREM

von Staudt-Clausen Theorem

$$B_{2n}=A_n-\sum_{\substack{p_k\\(p_k-1)|2n}}\frac{1}{p_k},$$

where B_{2n} is a BERNOULLI NUMBER, A_n is an INTEGER, and the p_ks are the PRIMES satisfying $p_k-1|2k$. For example, for $k=1$, the primes included in the sum are 2 and 3, since $(2-1)|2$ and $(3-1)|2$. Similarly, for $k=6$, the included primes are (2, 3, 5, 7, 13), since (1, 2, 3, 6, 12) divide $12=2\cdot 6$. The first few values of A_n for $n=1$, 2, ... are 1, 1, 1, 1, 1, 1, 2, -6, 56, -528, ... (Sloane's A000146).

The theorem was rediscovered by Ramanujan (Hardy 1999, p. 11) and can be proved using P-ADIC NUMBERS.

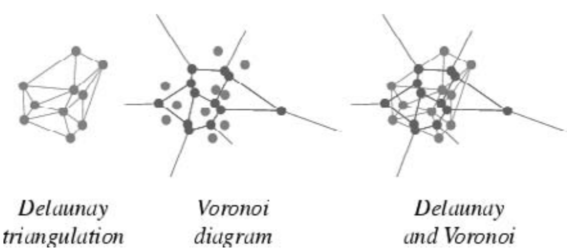
Voronoi Cell



The generalization of a VORONOI POLYGON to n-D, for $n>2$.

See also DODECAHEDRAL CONJECTURE, VORONOI POLYGON

Voronoi Diagram

The partitioning of a plane with n points into n convex POLYGONS such that each POLYGON contains exactly one point and every point in a given POLYGON is closer to its central point than to any other. A Voronoi diagram is sometimes also known as a DIRICHLET TESSELLATION. The cells are called DIRICHLET REGIONS, THIESSEN POLYTOPES, or VORONOI POLYGONS. The *Mathematica* command `DiagramPlot[`*pts*`]` in the *Mathematica* add-on package `DiscreteMath'ComputationalGeometry'` (which can be loaded with the command `<<DiscreteMath'`) plots the Voronoi diagram of the given list of points.

The DELAUNAY TRIANGULATION and Voronoi diagram in $\mathbb{R}^2$ are dual to each other.

Voting

The simple process of voting leads to surprisingly counterintuitive paradoxes. For example, if three people vote for three candidates, giving the rankings A, B, C; B, C, A; and C, A, B. A majority prefers A to B, B to C, but also C to A (Gardner 1984, p. 25)! It is also possible to conduct a secret ballot even if the votes are sent in to a central polling station (Lipton and Widgerson, Honsberger 1985).

VR Number

A "visual representation" number which is a sum of some simple function of its digits. For example,

$$1233 = 12^2 + 33^2$$

$$2661653 = 1653^2 - 266^2$$

$$221859 = 22^3 + 18^3 + 59^3$$

$$40585 = 4! + 0! + 5! + 8! + 5!$$

$$148349 = !1 + !4 + !8 + !3 + !4 + !9$$

$$4913 = (4 + 9 + 1 + 3)^3$$

are all VR numbers given by Madachy (1979).

Wallace-Simson Line

SIMSON LINE

Wallace-Simson Theorem

SIMSON LINE

Wallis Cosine Formula

$$\int_0^{\pi/2} \cos^n x\, dx = \begin{cases} \dfrac{\pi}{2}\dfrac{1\cdot 3\cdot 5\cdots(n-1)}{2\cdot 4\cdot 6\cdots n} & \text{for } n = 2, 4, \ldots \\ \dfrac{2\cdot 4\cdot 6\cdots(n-1)}{1\cdot 3\cdot 5\cdots n} & \text{for } n = 3, 5, \ldots. \end{cases}$$

See also WALLIS FORMULA, WALLIS SINE FORMULA

Wallis Formula

The Wallis formula follows from the INFINITE PRODUCT representation of the SINE

$$\sin x = x \prod_{n=1}^{\infty} \left(1 - \frac{x^2}{\pi^2 n^2}\right). \tag{1}$$

Taking $x = \pi/2$ gives

$$1 = \frac{\pi}{2} \prod_{n=1}^{\infty} \left[1 - \frac{1}{(2n)^2}\right] = \frac{\pi}{2} \prod_{n=1}^{\infty} \left[\frac{(2n)^2 - 1}{(2n)^2}\right], \tag{2}$$

so

$$\frac{\pi}{2} = \prod_{n=1}^{\infty} \left[\frac{(2n)^2}{(2n-1)(2n+1)}\right] = \frac{2\cdot 2}{1\cdot 3}\frac{4\cdot 4}{3\cdot 5}\frac{6\cdot 6}{5\cdot 7}\cdots. \tag{3}$$

A derivation due to Y. L. Yung uses the RIEMANN ZETA FUNCTION. Define

$$F(s) \equiv -\mathrm{Li}_s(-1) = \sum_{n=1}^{\infty} \frac{(-1)^n}{n^s}$$

$$= \left(1 - 2^{1-s}\right)\zeta(s) \tag{4}$$

$$F'(s) = \sum_{n=1}^{\infty} \frac{(-1)^n \ln n}{n^s}, \tag{5}$$

so

$$F'(0) = \sum_{n=1}^{\infty} (-1)^n \ln n = -\ln 1 + \ln 2 - \ln 3 + \ldots$$

$$= \ln\left(\frac{2\cdot 4\cdot 6\cdots}{1\cdot 3\cdot 5\cdots}\right). \tag{6}$$

Taking the derivative of the zeta function expression gives

$$\frac{d}{ds}\left(1 - 2^{1-s}\right)\zeta(s) = 2^{1-s}(\ln 2)\zeta(s) + \left(1 - 2^{1-s}\right)\zeta'(s) \tag{7}$$

$$\left[\frac{d}{ds}\left(1 - 2^{1-s}\right)\zeta(s)\right]_{s=0} = -\ln 2 - \zeta'(0)$$

$$= -\ln 2 + \frac{1}{2}\ln(2\pi) = \ln\left(\frac{\sqrt{2\pi}}{2}\right) = \ln\left(\sqrt{\frac{\pi}{2}}\right). \tag{8}$$

Equating and squaring then gives the Wallis formula, which can also be expressed

$$\frac{\pi}{2} = \left[4^{\zeta(0)} e^{-\zeta'(0)}\right]^2. \tag{9}$$

The q-ANALOG of the Wallis formula for $q = 2$ is

$$\prod_{k=1}^{\infty} \left(1 - q^{-k}\right)^{-1} = 3.4627466194\ldots \tag{10}$$

(Finch).

Wallis's Problem

Find nontrivial solutions to $\sigma(x^2) = \sigma(y^2)$ other than $(x, y) = (4, 5)$, where $\sigma(n)$ is the DIVISOR FUNCTION. Nontrivial solutions means that solutions which are multiples of smaller solutions are not considered. For example, multiples m of $(x, y) = (4, 5)$ are solutions for $m = 3$, 7, 9, 11, 13, 17, 19, 23, 21, ...

Nontrivial solutions to Wallis's equation include $(x, y) = (4, 5)$, (326, 407), (406, 489), (627, 749), (740, 878), (880, 1451), (888, 1102), (1026, 1208), (1110, 1943), (1284, 1528, 1605), (1510, 1809), (1628, 1630, 2035), (1956, 2030, 2445), (2013, 2557), (2072, 3097), (2508, 2996, 3135, 3745), ...

Walsh Function

Functions consisting of a number of fixed-amplitude square pulses interposed with zeros. Following Harmuth (1969), designate those with EVEN symmetry $\text{Cal}(k, t)$ and those with ODD symmetry $\text{Sal}(k, t)$. Define the SEQUENCY k as half the number of zero crossings in the time base. Walsh functions with nonidentical SEQUENCIES are ORTHOGONAL, as are the functions $\text{Cal}(k, t)$ and $\text{Sal}(k, t)$. The product of two Walsh functions is also a Walsh function. The Walsh functions are then given by

$$\text{Wal}(k, t) = \begin{cases} \text{Cal}(k/2, t) & \text{for } k = 0, 2, 4, \ldots \\ \text{Sal}((k+1)/2, t) & \text{for } k = 1, 3, 5, \ldots. \end{cases}$$

The Walsh functions $\text{Cal}(k, t)$ for $k = 0$, 1, ..., $n/2 - 1$ and $\text{Sal}(k, t)$ for $k = 1$, 2, ..., $n/2$ are given by the rows of the HADAMARD MATRIX H_n.

Wang's Conjecture

Wang's conjecture states that if a set of tiles can tile the plane, then they can always be arranged to do so periodically (Wang 1961). The CONJECTURE was refuted when Berger (1966) showed that an aperiodic set of tiles existed. Berger used 20,426 tiles, but the number has subsequently been greatly reduced. In fact, Culik (1996) has reduced the number of tiles to 13.

Ward's Primality Test

Let N be an ODD INTEGER, and assume there exists a LUCAS SEQUENCE $\{U_n\}$ with associated SYLVESTER CYCLOTOMIC NUMBERS $\{Q_n\}$ such that there is an $n > \sqrt{N}$ (with n and N RELATIVELY PRIME) for which N DIVIDES Q_n. Then N is a PRIME unless it has one of the following two forms:

1. $N = (n-1)^2$, with $n-1$ PRIME and $n > 4$, or
2. $N = n^2 - 1$, with $n-1$ and $n+1$ PRIME.

Waring's Conjecture

WARING'S PRIME NUMBER CONJECTURE, WARING'S PROBLEM

Waring's Prime Number Conjecture

Every ODD INTEGER n is a PRIME or the sum of three PRIMES. This problem is closely related to VINOGRADOV'S THEOREM.

See also GOLDBACH CONJECTURE, SCHNIRELMANN'S THEOREM, VINOGRADOV'S THEOREM

Waring's Problem

In his *Meditationes algebraicae*, Waring (1770, 1782) proposed a generalization of LAGRANGE'S FOUR-SQUARE THEOREM, stating that every RATIONAL INTEGER is the sum of a fixed number $g(n)$ of nth POWERS of INTEGERS, where n is any given POSITIVE INTEGER and $g(n)$ depends only on n. Waring originally speculated that $g(2) = 4$, $g(3) = 9$, and $g(4) = 19$. In 1909, Hilbert proved the general conjecture using an identity in 25-fold multiple integrals (Rademacher and Toeplitz 1957, pp. 52–1).

In LAGRANGE'S FOUR-SQUARE THEOREM, Lagrange proved that $g(2) = 4$, where 4 may be reduced to 3 except for numbers OF THE FORM $4^n(8k+7)$ (as proved by Legendre; Hardy 1999, p. 12). In the early twentieth century, Dickson, Pillai, and Niven proved that $g(3) = 9$. Hilbert, Hardy, and Vinogradov proved $g(4) \le 21$, and this was subsequently reduced to $g(4) = 19$ by Balasubramanian *et al.* (1986). Liouville

proved (using LAGRANGE'S FOUR-SQUARE THEOREM and LIOUVILLE POLYNOMIAL IDENTITY) that $g(5) \leq 53$, and this was improved to 47, 45, 41, 39, 38, and finally $g(5) \leq 37$ by Wieferich. See Rademacher and Toeplitz (1957, p. 56) for a simple proof. J.-J. Chen (1964) proved that $g(5) = 37$.

Dickson (1936), Pillai (1936), and Niven also conjectured an explicit formula for $g(s)$ for $s > 6$ (Bell 1945, pp. 318 and 602), based on the relationship

$$\left(\frac{3}{2}\right)^n - \left\lfloor\left(\frac{3}{2}\right)^n\right\rfloor = 1 - \left(\frac{1}{2}\right)^n \left\{\left\lfloor\left(\frac{3}{2}\right)^n + 2\right\rfloor\right\}. \quad (1)$$

If the DIOPHANTINE (i.e., n is restricted to being an INTEGER) inequality

$$\text{frac}\left[\left(\frac{3}{2}\right)^n\right] \leq 1 - \left(\frac{3}{4}\right)^n \quad (2)$$

is true, where frac(x) is the FRACTIONAL PART of x, then

$$g(n) = 2^n + \left\lfloor\left(\frac{3}{2}\right)^n\right\rfloor - 2. \quad (3)$$

This was given as a lower bound by Euler, and has been verified to be correct for $6 \leq n \leq 471{,}600{,}000$ (Kubina and Wunderlich 1990, extending Stemmler 1990). Furthermore, Mahler (1957) proved that at most a FINITE number of n exceed Euler's lower bound. Unfortunately, the proof is nonconstructive.

There is also a related (but more difficult) problem of finding the least INTEGER n such that every POSITIVE INTEGER beyond a certain point (i.e., all but a FINITE number) is the SUM of G_n nth POWERS. From 1920–928, Hardy and Littlewood showed that

$$G(n) \leq (n-2)2^{n-1} + 5 \quad (4)$$

and conjectured that

$$G(k) < \begin{cases} 2k+1 & \text{for } k \text{ not a power of 2} \\ 4k & \text{for } k \text{ a power of 2.} \end{cases} \quad (5)$$

The best currently known bound is

$$G(k) < ck \ln k \quad (6)$$

for some constant c. Heilbronn (1936) improved Vinogradov's results to obtain

$$G(n) \leq 6n \ln n + \left[4 + 3 \ln\left(3 + \frac{2}{n}\right)\right] n + 3. \quad (7)$$

It has long been known that $G(2) = 4$.

Dickson and Landau proved that the only INTEGERS requiring nine CUBES are 23 and 239, thus establishing $G(3) \leq 8$. Wieferich proved that only 15 INTEGERS require eight CUBES: 15, 22, 50, 114, 167, 175, 186, 212, 231, 238, 303, 364, 420, 428, and 454 (Sloane's A018889), establishing $G(3) \leq 7$ (Wells 1986, p. 70). The largest number known requiring seven CUBES is 8042.

In 1933, Hardy and Littlewood showed that $G(4) \leq 19$, but this was improved in 1936 to 16 or 17, and shown to be exactly 16 by Davenport (1939b). Vaughan (1986) greatly improved on the method of Hardy and Littlewood, obtaining improved results for $n \geq 5$. These results were then further improved by Brüdern (1990), who gave $G(5) \leq 18$, and Wooley (1992), who gave G_n for $n = 6$ to 20. Vaughan and Wooley (1993) showed $G(8) \leq 42$.

Let $G^+(n)$ denote the smallest number such that *almost all* sufficiently large INTEGERS are the sum of $G^+(n)$ nth POWERS. Then $G^+(3) = 4$ (Davenport 1939a), $G^+(4) = 15$ (Hardy and Littlewood 1925), $G^+(8) = 32$ (Vaughan 1986), and $G^+(16) = 64$ (Wooley 1992). If the negatives of POWERS are permitted in addition to the powers themselves, the largest number of nth POWERS needed to represent an arbitrary integer are denoted $eg(n)$ and $EG(n)$ (Wright 1934, Hunter 1941, Gardner 1986). In general, these values are much harder to calculate than are $g(n)$ and G_n.

The following table gives $g(n)$, G_n, $G^+(n)$, $eg(n)$, and $EG(n)$ for $n \leq 20$. The sequence of $g(n)$ is Sloane's A002804.

n	$g(n)$	G_n	$G^+(n)$	$eg(n)$	$EG(n)$
2	4	4		3	3
3	9	≤ 7	≤ 4	[4, 5]

Waring's Sum Conjecture

WARING'S PROBLEM

Waring's Theorem

If each of two curves meets the LINE AT INFINITY in distinct, nonsingular points, and if all their intersections are finite, then if to each common point there is attached a weight equal to the number of intersections absorbed therein, the CENTER OF MASS of these points is the center of gravity of the intersections of the asymptotes.

Wasteful Number

A number n is called wasteful if the number of digits in the prime factorization of n (including powers) uses more digits than the number of digits in n. The first few wasteful numbers are 4, 6, 8, 9, 12, 18, 20, 22, 24 ... (Sloane's A046760). Pinch calls these numbers "frugal" and includes 1 as a frugal number.

Watson Quintuple Product Identity

QUINTUPLE PRODUCT IDENTITY

Watson-Nicholson Formula

Let $H_\nu^{(\iota)}(x)$ be a HANKEL FUNCTION OF THE FIRST or SECOND KIND, let $x, \nu > 0$, and define

$$w = \sqrt{\left(\frac{x}{\nu}\right)^2 - 1}.$$

Then

$$H_\nu^{(\iota)}(x) = 3^{-1/2} w \exp\{(-1)^{\iota+1} i[\pi/6 + \nu(w - \tfrac{1}{3}w^3 - \tan^{-1} w)]\} H_{1/3}^{(\iota)}(\tfrac{1}{3}\nu w) + \mathrm{O}\left|\nu^{-1}\right|.$$

References

Iyanaga, S. and Kawada, Y. (Eds.). *Encyclopedic Dictionary of Mathematics.* Cambridge, MA: MIT Press, p. 1475, 1980.

Watson's Formula

Let $J_\nu(z)$ be a BESSEL FUNCTION OF THE FIRST KIND, $Y_\nu(z)$ a BESSEL FUNCTION OF THE SECOND KIND, and $K_\nu(z)$ a MODIFIED BESSEL FUNCTION OF THE FIRST KIND. Also let $\Re[z] > 0$ and require $\Re[\mu - \nu] < 1$. Then

$$J_\mu(z)Y_\nu(z) - J_\nu(z)Y_\mu(z) = \frac{4 \sin[(\mu - \nu)\pi]}{\pi^2} \int_0^\infty K_{\nu-\mu}(2z \sinh t) e^{-(\mu+\nu)t}\, dt.$$

The fourth edition of Gradshteyn and Ryzhik (2000), Iyanaga and Kawada (1980), and Ito (1987) erroneously give the exponential with a PLUS SIGN. A related integral is given by

$$J_\nu(z)\frac{\partial Y_\nu(z)}{\partial \nu} - Y_\nu(z)\frac{\partial J_\nu(z)}{\partial \nu} = -\frac{4}{\pi}\int_0^\infty K_0(2z \sinh t) e^{-2\nu t}\, dt$$

for $\Re[z] > 0$.

Watt's Curve

A curve named after James Watt (1736–819), the Scottish engineer who developed the steam engine (MacTutor Archive). The curve is produced by a LINKAGE of rods connecting two wheels of equal diameter. Let the two wheels have RADIUS b and let their centers be located a distance $2a$ apart. Further suppose that a rod of length $2c$ is fixed at each end to the CIRCUMFERENCE of the two wheels. Let P be the MIDPOINT of the rod. Then Watt's curve C is the LOCUS of P.
The POLAR equation of Watt's curve is

$$r^2 = b^2 - \left(a \sin\theta \pm \sqrt{c^2 - a^2 \cos^2\theta}\right)^2.$$

If $a = c$, then C is a CIRCLE of RADIUS b with a figure of eight inside it.

Wave Equation

The wave equation is the important PARTIAL DIFFERENTIAL EQUATION

$$\nabla^2\psi = \frac{1}{v^2}\frac{\partial^2\psi}{\partial t^2}, \tag{1}$$

which can also be written

$$v^2\nabla^2\psi = \psi_{tt}, \tag{2}$$

where ∇^2 is the LAPLACIAN, or

$$\Box^2\psi = 0, \tag{3}$$

where $\Box^2$ is the D'ALEMBERTIAN.
The 1-D wave equation is

$$\frac{\partial^2\psi}{\partial x^2} = \frac{1}{v^2}\frac{\partial^2\psi}{\partial t^2}. \tag{4}$$

In order to specify a wave, the equation is subject to boundary conditions

$$\psi(0, t) = 0 \tag{5}$$

$$\psi(L, t) = 0, \tag{6}$$

and initial conditions

$$\psi(x, 0) = f(x) \tag{7}$$

$$\frac{\partial\psi}{\partial t}(x, 0) = g(x). \tag{8}$$

The wave equation can be solved using the so-called d'Alembert's solution, a FOURIER TRANSFORM method, or SEPARATION OF VARIABLES.

d'Alembert devised his solution in 1746, and Euler subsequently expanded the method in 1748. Let

$$\xi \equiv x - at \tag{9}$$

$$\eta \equiv x + at. \tag{10}$$

By the CHAIN RULE,

$$\frac{\partial^2 \psi}{\partial x^2} = \frac{\partial^2 \psi}{\partial \xi^2} + 2\frac{\partial^2 \psi}{\partial \xi \partial \eta} + \frac{\partial^2 \psi}{\partial \eta^2} \tag{11}$$

$$\frac{1}{v^2}\frac{\partial^2 \psi}{\partial t^2} = \frac{\partial^2 \psi}{\partial \xi^2} - 2\frac{\partial^2 \psi}{\partial \xi \partial \eta} + \frac{\partial^2 \psi}{\partial \eta^2}. \tag{12}$$

The wave equation then becomes

$$\frac{\partial^2 \psi}{\partial \xi \partial \eta} = 0. \tag{13}$$

Any solution of this equation is OF THE FORM

$$\psi(\xi, \eta) = f(\eta) + g(\xi) = f(x + vt) + g(x - vt), \tag{14}$$

where f and g are *any* functions. They represent two waveforms traveling in opposite directions, f in the NEGATIVE x direction and g in the POSITIVE x direction.

The 1-D wave equation can also be solved by applying a FOURIER TRANSFORM to each side,

$$\int_{-\infty}^{\infty} \frac{\partial^2 \psi(x,t)}{\partial x^2} e^{-2\pi ikx} dx = \frac{1}{v^2}\int_{-\infty}^{\infty} \frac{\partial^2 \psi(x,t)}{\partial t^2} e^{-2\pi ikx} dx, \tag{15}$$

which is given, with the help of the FOURIER TRANSFORM DERIVATIVE identity, by

$$(2\pi ik)^2 \Psi(k,t) = \frac{1}{v^2}\frac{\partial^2 \Psi(k,t)}{\partial t^2}, \tag{16}$$

where

$$\Psi(k,t) \equiv F[\psi(x,t)] = \int_{-\infty}^{\infty} \psi(x,t) e^{-2\pi ikx} dx. \tag{17}$$

This has solution

$$\Psi(k,t) \equiv A(k)e^{2\pi ikvt} + B(k)e^{-2\pi ikvt}. \tag{18}$$

Taking the inverse FOURIER TRANSFORM gives

$$\begin{aligned}\psi(x,t) &\equiv \int_{-\infty}^{\infty} \Psi(k,t) e^{2\pi ikx} dx \\ &= \int_{-\infty}^{\infty} \left[A(k)e^{2\pi ikvt} + B(k)e^{-2\pi ikvt}\right] e^{-2\pi ikx} dk \\ &= \int_{-\infty}^{\infty} A(k)e^{-2\pi ik(x-vt)} dk + \int_{-\infty}^{\infty} B(k)e^{-2\pi ik(x+vt)} dk \\ &= f_1(x - vt) + f_2(x + vt),\end{aligned} \tag{19}$$

where

$$f_1(u) \equiv \mathcal{F}[A(k)] = \int_{-\infty}^{\infty} A(k)e^{-2\pi iku} dk \tag{20}$$

$$f_2(u) \equiv \mathcal{F}[B(k)] = \int_{-\infty}^{\infty} B(k)e^{-2\pi iku} dk. \tag{21}$$

This solution is still subject to all other initial and boundary conditions.

The 1-D wave equation can be solved by SEPARATION OF VARIABLES using a trial solution

$$\psi(x,t) = X(x)T(t). \tag{22}$$

This gives

$$T\frac{d^2X}{dx^2} = \frac{1}{v^2}X\frac{d^2T}{dt^2} \tag{23}$$

$$\frac{1}{X}\frac{d^2X}{dx^2} = \frac{1}{v^2}\frac{1}{T}\frac{d^2T}{dt^2} = -k^2. \tag{24}$$

So the solution for X is

$$X(x) = C\cos(kx) + D\sin(kx). \tag{25}$$

Rewriting (24) gives

$$\frac{1}{T}\frac{d^2T}{dt^2} = -v^2k^2 \equiv -\omega^2, \tag{26}$$

so the solution for T is

$$T(t) = E\cos(\omega t) + F\sin(\omega t), \tag{27}$$

where $v \equiv \omega/k$. Applying the boundary conditions $\psi(0,t) = \psi(L,t) = 0$ to (25) gives

$$C = 0 \quad kL = m\pi, \tag{28}$$

where m is an INTEGER. Plugging (25), (27) and (28) back in for ψ in (23) gives, for a particular value of m,

$$\begin{aligned}\psi_m(x,t) &= [E_m \sin(\omega_m t) + F_m \cos(\omega_m t)] D_m \sin\left(\frac{m\pi x}{L}\right) \\ &\equiv [A_m \cos(\omega_m t) + B_m \sin(\omega_m t)] \sin\left(\frac{m\pi x}{L}\right).\end{aligned} \tag{29}$$

The initial condition $\psi(x,0) = 0$ then gives $B_m = 0$, so (29) becomes

$$\psi_m(x,t) = A_m \cos(\omega_m t)\sin\left(\frac{m\pi x}{L}\right). \tag{30}$$

The general solution is a sum over all possible values of m, so

$$\psi(x,t) = \sum_{m=1}^{\infty} A_m \cos(\omega_m t)\sin\left(\frac{m\pi x}{L}\right). \tag{31}$$

Using ORTHOGONALITY of sines again,

$$\int_0^L \sin\left(\frac{l\pi x}{L}\right)\sin\left(\frac{m\pi x}{L}\right) dx = \tfrac{1}{2}L\delta_{lm}, \tag{32}$$

where δ_{lm} is the KRONECKER DELTA defined by

$$\delta_{mn} \equiv \begin{cases} 1 & m = n \\ 0 & m \neq n \end{cases}, \tag{33}$$

gives

$$\int_0^L \psi(x,0) \sin\left(\frac{m\pi x}{L}\right) dx$$

$$= \sum_{l=1}^{\infty} A_l \sin\left(\frac{l\pi x}{L}\right) \sin\left(\frac{m\pi x}{L}\right) dx$$

$$= \sum_{l=1}^{\infty} A_l \tfrac{1}{2} L \delta_{lm} = \tfrac{1}{2} L A_m, \tag{34}$$

so we have

$$A_m = \frac{2}{L} \int_0^L \psi(x,0) \sin\left(\frac{m\pi x}{L}\right) dx. \tag{35}$$

The computation of A_ms for specific initial distortions is derived in the FOURIER SINE SERIES section. We already have found that $B_m = 0$, so the equation of motion for the string (31), with

$$\omega_m \equiv v k_m = \frac{v m \pi}{L}, \tag{36}$$

is

$$\psi(x,t) = \sum_{m=1}^{\infty} A_m \cos\left(\frac{v m \pi t}{L}\right) \sin\left(\frac{m\pi x}{L}\right), \tag{37}$$

where the A_m COEFFICIENTS are given by (35).

A damped 1-D wave

$$\frac{\partial^2 \psi}{\partial x^2} = \frac{1}{v^2} \frac{\partial^2 \psi}{\partial t^2} + b \frac{\partial \psi}{\partial t}, \tag{38}$$

given boundary conditions

$$\psi(0,t) = 0 \tag{39}$$

$$\psi(L,t) = 0, \tag{40}$$

initial conditions

$$\psi(x,0) = f(x) \tag{41}$$

$$\frac{\partial \psi}{\partial t}(x,0) = g(x) \tag{42}$$

and the additional constraint

$$0 < b < \frac{2\pi}{Lv}, \tag{43}$$

can also be solved as a FOURIER SERIES.

$$\psi(x,t) = \sum_{n=1}^{\infty} \sin\left(\frac{n\pi x}{L}\right) e^{-v^2 bt/2} [a_n \sin(\mu_n t) + b_n \cos(\mu_n t)], \tag{44}$$

where

$$\mu_n \equiv \frac{\sqrt{4v^2 n^2 \pi^2 - b^2 L^2 v^4}}{2L} = \frac{v\sqrt{4n^2\pi^2 - b^2 L^2 v^2}}{2L} \tag{45}$$

$$b_n = \frac{2}{L} \int_0^L \sin\left(\frac{n\pi x}{L}\right) f(x)\, dx \tag{46}$$

$$a_n = \frac{2}{L\mu_n} \left\{ \int_0^L \sin\left(\frac{n\pi x}{L}\right) \left[g(x) + \frac{v^2 b}{2} f(x) \right] dx \right\}. \tag{47}$$

To find the motion of a rectangular membrane with sides of length L_x and L_y (in the absence of gravity), use the 2-D wave equation

$$\frac{\partial^2 z}{\partial x^2} + \frac{\partial^2 z}{\partial y^2} = \frac{1}{v^2} \frac{\partial^2 z}{\partial t^2}, \tag{48}$$

where $z(x,y,t)$ is the vertical displacement of a point on the membrane at position (x, y) and time t. Use SEPARATION OF VARIABLES to look for solutions OF THE FORM

$$z(x,y,t) = X(x)Y(y)T(t). \tag{49}$$

Plugging (49) into (48) gives

$$YT \frac{d^2 X}{dx^2} + XT \frac{d^2 Y}{dy^2} = \frac{1}{v^2} XY \frac{d^2 T}{dt^2}, \tag{50}$$

where the partial derivatives have now become complete derivatives. Multiplying (50) by v^2/XYT gives

$$\frac{v^2}{X} \frac{d^2 X}{dx^2} + \frac{v^2}{Y} \frac{d^2 Y}{dy^2} = \frac{1}{T} \frac{d^2 T}{dt^2}. \tag{51}$$

The left and right sides must both be equal to a constant, so we can separate the equation by writing the right side as

$$\frac{1}{T} \frac{d^2 T}{dt^2} = -\omega^2. \tag{52}$$

This has solution

$$T(t) = C_\omega \cos(\omega t) + D_\omega \sin(\omega t). \tag{53}$$

Plugging (52) back into (51),

$$\frac{v^2}{X} \frac{d^2 X}{dx^2} + \frac{v^2}{Y} \frac{d^2 Y}{dy^2} = -\omega^2, \tag{54}$$

which we can rewrite as

$$\frac{1}{X} \frac{d^2 X}{dx^2} = -\frac{1}{Y} \frac{d^2 Y}{dy^2} - \frac{\omega^2}{v^2} = -k_x^2 \tag{55}$$

since the left and right sides again must both be equal to a constant. We can now separate out the $Y(y)$ equation

$$\frac{1}{Y}\frac{d^2Y}{dy^2} = k_x^2 - \frac{\omega^2}{v^2} \equiv -k_y^2, \tag{56}$$

where we have defined a new constant k_y satisfying

$$k_x^2 + k_y^2 = \frac{\omega^2}{v^2}. \tag{57}$$

Equations (55) and (56) have solutions

$$X(x) = E\cos(k_x x) + F\sin(k_x x) \tag{58}$$

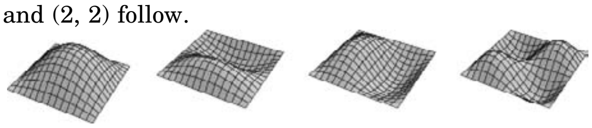
$$Y(y) = G\cos(k_y y) + H\sin(k_y y). \tag{59}$$

We now apply the boundary conditions to (58) and (59). The conditions $z(0,y,t)=0$ and $z(x,0,t)=0$ mean that

$$E = 0 \quad G = 0. \tag{60}$$

Similarly, the conditions $z(L_x, y, t) = 0$ and $z(x, L_y, t) = 0$ give $\sin(k_x L_x) = 0$ and $\sin(k_y L_y) = 0$, so $L_x k_x = p\pi$ and $L_y k_y = q\pi$, where p and q are INTEGERS. Solving for the allowed values of k_x and k_y then gives

$$k_x = \frac{p\pi}{L_x} \quad k_y = \frac{q\pi}{L_y}. \tag{61}$$



Plugging (54), (58), (59), (60), and (61) back into (24) gives the solution for particular values of p and q,

$$z_{pq}(x,y,t) = [C_\omega \cos(\omega t) + D_\omega \sin(\omega t)]\left[F_p \sin\left(\frac{p\pi x}{L_x}\right)\right] \times \left[H_q \sin\left(\frac{q\pi y}{L_y}\right)\right]. \tag{62}$$

Lumping the constants together by writing $A_{pq} \equiv C_\omega F_p H_q$ (we can do this since ω is a function of p and q, so C_ω can be written as C_{pq}) and $B_{pq} \equiv D_\omega F_p H_q$, we obtain

$$z_{pq}(x,y,t) = \left[A_{pq}\cos(\omega_{pq}t) + B_{pq}\sin(\omega_{pq}t)\right] \times \sin\left(\frac{p\pi x}{L_x}\right)\sin\left(\frac{q\pi y}{L_y}\right). \tag{63}$$

Plots of the spatial part for modes (1, 1), (1, 2), (2, 1), and (2, 2) follow.

The general solution is a sum over all possible values of p and q, so the final solution is

$$z(x,y,t) = \sum_{p=1}^{\infty}\sum_{q=1}^{\infty}[A_{pq}\cos(\omega_{pq}t) + B_{pq}\sin(\omega_{pq}t)]\sin\left(\frac{p\pi x}{L_x}\right)\sin\left(\frac{q\pi y}{L_y}\right), \tag{64}$$

where ω is defined by combining (57) and (61) to yield

$$\omega_{pq} \equiv \pi v\sqrt{\left(\frac{p}{L_z}\right)^2 + \left(\frac{q}{L_y}\right)^2}. \tag{65}$$

Given the initial conditions $z(x,y,0)$ and $\frac{\partial z}{\partial t}(x,y,0)$, we can compute the A_{pq}s and B_{pq}s explicitly. To accomplish this, we make use of the orthogonality of the SINE function in the form

$$I \equiv \int_0^L \sin\left(\frac{m\pi x}{L}\right)\sin\left(\frac{n\pi x}{L}\right)dx = \tfrac{1}{2}L\delta_{mn}, \tag{66}$$

where δ_{mn} is the KRONECKER DELTA. This can be demonstrated by direct INTEGRATION. Let $u \equiv \pi x/L$ so $du = (\pi/L)\,dx$ in (66), then

$$I = \frac{L}{\pi}\int_0^\pi \sin(mu)\sin(nu)\,du. \tag{67}$$

Now use the trigonometric identity

$$\sin\alpha\sin\beta = \tfrac{1}{2}[\cos(\alpha-\beta) - \cos(\alpha+\beta)] \tag{68}$$

to write

$$I = \frac{L}{2\pi}\int_0^\pi \cos[(m-n)u]\,du + \int_0^\pi \cos[(m+n)u]\,du. \tag{69}$$

Note that for an INTEGER $l \neq 0$, the following INTEGRAL vanishes

$$\int_0^\pi \cos(lu)\,du = \frac{1}{l}[\sin(lu)]_0^\pi = \frac{1}{l}[\sin(lu) - \sin 0] = \frac{1}{l}\sin(l\pi) = 0, \tag{70}$$

since $\sin(l\pi) = 0$ when l is an INTEGER. Therefore, $I = 0$ when $l \equiv m - n \neq 0$. However, I does *not* vanish when $l = 0$, since

$$\int_0^\pi \cos(0\cdot u)\,du = \int_0^\pi du = \pi. \tag{71}$$

We therefore have that $I = L\delta_{mn}/2$, so we have derived (66). Now we multiply $z(x,y,0)$ by two sine terms and integrate between 0 and L_x and between 0 and L_y,

$$I = \int_0^{L_y}\left[\int_0^{L_x} z(x,y,0)\sin\left(\frac{p\pi x}{L_x}\right)dx\right]\sin\left(\frac{q\pi y}{L_y}\right)dy. \tag{72}$$

Now plug in $z(x,y,t)$, set $t = 0$, and prime the indices to distinguish them from the p and q in (72),

$$I = \sum_{q'=1}^{\infty} \int_0^{L_y} \left[\sum_{p'=1}^{\infty} A_{p'q'} \int_0^{L_x} \sin\left(\frac{p\pi x}{L_x}\right) \sin\left(\frac{p'\pi x}{L_x}\right) dx \right]$$
$$\times \sin\left(\frac{q\pi y}{L_y}\right) \sin\left(\frac{q'\pi y}{L_y}\right) dy. \quad (73)$$

Making use of (66) in (73),

$$I = \sum_{q'=1}^{\infty} \int_0^{L_y} \sum_{p'=1}^{\infty} A_{p'q'} \frac{L_x}{2} \delta_{p,p'} \left(\frac{q\pi y}{L_y}\right) \sin\left(\frac{q'\pi y}{L_y}\right) dy, \quad (74)$$

so the sums over p' and q' collapse to a single term

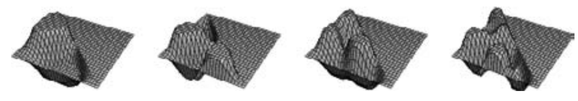
$$I = \frac{L_x}{2} \sum_{p=1}^{\infty} A_{pq'} \frac{L_y}{2} \delta_{q,q'} \frac{L_x L_y}{4} A_{pq}. \quad (75)$$

Equating (74) and (75) and solving for A_{pq} then gives

$$A_{pq} = \frac{4}{L_x L_y} \int_0^{L_y} \left[\int_0^{L_x} z(x,y,0) \sin\left(\frac{p\pi x}{L_x}\right) dx \right] \sin\left(\frac{q\pi x}{L_y}\right) dy. \quad (76)$$

An analogous derivation gives the B_{pq}s as

$$B_{pq} = \frac{4}{\omega_{pq} L_x L_y} \int_0^{L_y} \left[\int_0^{L_x} \frac{\partial z}{\partial t}(x,y,0) \sin\left(\frac{p\pi x}{L_x}\right) dx \right]$$
$$\times \sin\left(\frac{q\pi x}{L_y}\right) dy. \quad (77)$$



The equation of motion for a membrane shaped as a RIGHT ISOSCELES TRIANGLE of length c on a side and with the sides oriented along the POSITIVE x and y axes is given by

$$\psi(x,y,t) = \left[C_{pq} \cos(\omega_{pq} t) + D_{pq} \sin(\omega_{pq} t)\right]$$
$$\times \left[\sin\left(\frac{p\pi x}{c}\right) \sin\left(\frac{q\pi y}{c}\right) - \sin\left(\frac{q\pi x}{c}\right) \sin\left(\frac{p\pi y}{c}\right) \right], \quad (78)$$

where

$$\omega_{pq} = \frac{\pi v}{c} \sqrt{p^2 + q^2} \quad (79)$$

and p, q INTEGERS with $p > q$. This solution can be obtained by subtracting two wave solutions for a square membrane with the indices reversed. Since points on the diagonal which are equidistant from the center must have the same wave equation solution (by symmetry), this procedure gives a wavefunction which will vanish along the diagonal *as long as p and q are both EVEN or ODD.* We must further restrict the modes since those with $p < q$ give wavefunctions which are just the NEGATIVE of (q, p) and (p, p) give an identically zero wavefunction. The following plots show (3, 1), (4, 2), (5, 1), and (5,3).

Wave Operator

An OPERATOR relating the asymptotic state of a DYNAMICAL SYSTEM governed by the Schrödinger equation

$$i \frac{d}{dt} \psi(t) = H \psi(t)$$

to its original asymptotic state.

See also SCATTERING OPERATOR

Wave Surface

A SURFACE represented parametrically by ELLIPTIC FUNCTIONS.

Wavelet

Wavelets are a class of a functions used to localize a given function in both space and scaling. A family of wavelets can be constructed from a function $\psi(x)$, sometimes known as a "mother wavelet," which is confined in a finite interval. "Daughter wavelets" $\psi^{a,b}(x)$ are then formed by translation (b) and contraction (a). Wavelets are especially useful for compressing image data, since a WAVELET TRANSFORM has properties which are in some ways superior to a conventional FOURIER TRANSFORM.

An individual wavelet can be defined by

$$\psi^{a,b}(x) = |a|^{-1/2} \psi\left(\frac{x-b}{a}\right). \quad (1)$$

Then

$$W_\psi(f)(a,b) = \frac{1}{\sqrt{a}} \int_{-\infty}^{\infty} f(t) \psi\left(\frac{t-b}{a}\right) dt, \quad (2)$$

and CALDERÓN'S FORMULA gives

$$f(x) = C_\psi \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \langle f, \psi^{a,b} \rangle \psi^{a,b}(x) a^{-2}\, da\, db. \qquad (3)$$

A common type of wavelet is defined using HAAR FUNCTIONS.

Wavelet Matrix

Any discrete finite WAVELET TRANSFORM can be REPRESENTED AS a matrix, and such a wavelet matrix can be computed in $\mathcal{O}(n)$ steps, compared to $\mathcal{O}(n \lg n)$ for the FOURIER MATRIX, where $\lg x = \log_2 x$ is the base-2 LOGARITHM. A single wavelet matrix can be built using HAAR FUNCTIONS.

See also FOURIER MATRIX, HAAR FUNCTION, WAVELET, WAVELET TRANSFORM

Wavelet Transform

A transform which localizes a function both in space and scaling and has some desirable properties compared to the FOURIER TRANSFORM. The transform is based on a WAVELET MATRIX, which can be computed more quickly than the analogous FOURIER MATRIX.

Weak Convergence

Weak convergence is usually either denoted $x_n \to^w x$ or $x_n \rightharpoonup x$. A SEQUENCE $\{x_n\}$ of VECTORS in an INNER PRODUCT SPACE E is called weakly convergent to a VECTOR in E if

$$\langle x_n, y \rangle \to \langle x, y \rangle \quad as\ n \to \infty, \quad \text{for all } y \in E.$$

Every STRONGLY CONVERGENT sequence is also weakly convergent (but the opposite does not usually hold). This can be seen as follows. Consider the sequence $\{x_n\}$ that converges strongly to x, i.e., $\|x_n - x\| \to 0$ as $n \to \infty$. SCHWARZ'S INEQUALITY now gives

$$|\langle x_n - x, y \rangle| \le \|x_n - x\| \|y\| \quad as\ n \to \infty.$$

The definition of weak convergence is therefore satisfied.

See also Inner Product Space, Schwarz's Inequality, Strong Convergence

Weak Law of Large Numbers

A result in probability theory also known as Bernoulli's theorem or the weak law of large numbers (in contrast to the strong law of large numbers). Let X_1, ..., X_n be a sequence of independent and identically distributed random variables, each having a mean $\langle X_i \rangle = \mu$ and standard deviation σ. Define a new variable

$$X \equiv \frac{X_1 + \ldots + X_n}{n}. \quad (1)$$

Then, as $n \to \infty$, the sample mean $\langle x \rangle$ equals the population mean μ of each variable.

$$\langle X \rangle = \left\langle \frac{X_1 + \ldots + X_n}{n} \right\rangle = \frac{1}{n}(\langle X_1 \rangle + \ldots + \langle X_n \rangle)$$

$$= \frac{n\mu}{n} = \mu. \quad (2)$$

In addition,

$$\operatorname{var}(X) = \operatorname{var}\left(\frac{X_1 + \ldots + X_2}{n}\right)$$

$$= \operatorname{var}\left(\frac{X_1}{n}\right) + \ldots + \operatorname{var}\left(\frac{X_n}{n}\right)$$

$$= \frac{\sigma^2}{n^2} + \ldots + \frac{\sigma^2}{n^2} = \frac{\sigma^2}{n}. \quad (3)$$

Therefore, by the Chebyshev inequality, for all $\epsilon > 0$,

$$P(|X - \mu| \geq \epsilon) \leq \frac{\operatorname{var}(X)}{\epsilon^2} = \frac{\sigma^2}{n\epsilon^2}. \quad (4)$$

As $n \to \infty$, it then follows that

$$\lim_{n \to \infty} P(|X - \mu| \geq \epsilon) = 0. \quad (5)$$

(Khintchine 1929). Stated another way, the probability that the average $|(X_1 + \ldots + X_n)/n - \mu| < \epsilon$ for ϵ an arbitrary positive quantity approaches 1 as $n \to \infty$ (Feller 1968, pp. 228–29).

Weakly Binary Tree

N.B. A detailed online essay by S. Finch was the starting point for this entry.

A rooted tree for which the root node is adjacent to at most two vertices, and all nonroot vertices are adjacent to at most three vertices. Let $b(n)$ be the number of weakly binary trees of order n, then $b(5) = 6$. Let

$$g(z) = \sum_{i=0}^{\infty} g_i z^i, \quad (1)$$

where

$$g_0 = 0 \quad (2)$$

$$g_1 = g_2 = g_3 = 1 \quad (3)$$

$$g_{2i+1} = \sum_{j=1}^{i} g_{2i+1-j} g_j \quad (4)$$

$$g_{2i} = \tfrac{1}{2} g_i (g_i + 1) \sum_{j=1}^{i-1} g_{2i-j} g_j. \quad (5)$$

Otter (Otter 1948, Harary and Palmer 1973, Knuth 1969) showed that

$$\lim_{n \to \infty} \frac{b(n) n^{3/2}}{\xi^n} = \eta, \quad (6)$$

where

$$\xi = 2.48325\ldots \quad (7)$$

is the unique positive root of

$$g\left(\frac{1}{x}\right) = 1, \quad (8)$$

and

$$\eta = 0.7916032\ldots. \quad (9)$$

ξ_1 is also given by

$$\xi = \lim_{n \to \infty} (c_n)^{2-n}, \quad (10)$$

where c_n is given by

$$c_0 = 2 \quad (11)$$

$$c_n = (c_{n-1})^2 + 2, \quad (12)$$

giving

$$\eta = \frac{1}{2}\sqrt{\frac{\xi}{\pi}}\sqrt{3+\frac{1}{c_1}+\frac{1}{c_1 c_2}+\frac{1}{c_1 c_2 c_3}+\ldots} \tag{13}$$

Weakly Complete Sequence

A SEQUENCE of numbers $V = \{v_n\}$ is said to be weakly complete if every POSITIVE INTEGER n beyond a certain point N is the sum of some SUBSEQUENCE of V (Honsberger 1985). Dropping two terms from the FIBONACCI NUMBERS produces a SEQUENCE which is not even weakly complete. However, the SEQUENCE

$$F'_n \equiv F_n - (-1)^n$$

is weakly complete, even with any finite subsequence deleted (Graham 1964).

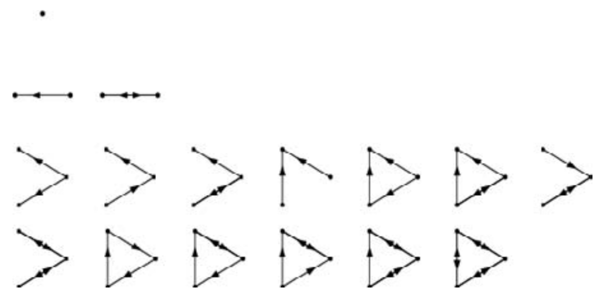
Weakly Connected Component



A weakly connected component is a maximal SUBGRAPH of a DIRECTED GRAPH such that for every pair of vertices u, v in the SUBGRAPH, there is an undirected path from u to v and a directed path from v to u. Weakly connected components can be found using `StronglyConnectedComponents[g]` in the *Mathematica* add-on package `DiscreteMath‘Combinatorica‘` (which can be loaded with the command `<<DiscreteMath‘`) (Skiena 1990, p. 172).

Weakly Connected Digraph

A DIRECTED GRAPH in which it is possible to reach any node starting from any other node by traversing edges in some direction (i.e., not necessarily in the direction they point). The nodes in a strongly connected digraph therefore must all have either OUT-DEGREE or INDEGREE of at least 1. The numbers of nonisomorphic simple weakly connected digraphs on $n = 1, 2, \ldots$ nodes are 1, 2, 13, 199, 9364, ... (Sloane's A003085).

Weakly Differentiable

See also DIFFERENTIABLE

Weakly Independent

An infinite sequence $\{a_i\}$ of POSITIVE INTEGERS is called weakly independent if any relation $\Sigma \epsilon_i a_i$ with $\epsilon_i = 0$ or ± 1 and $\epsilon_i = 0$, except finitely often, IMPLIES $\epsilon_i = 0$ for all i.

Weber Differential Equations

Consider the differential equation satisfied by

$$w = z^{-1/2} W_{k,-1/4}\left(\tfrac{1}{2}z^2\right), \quad (1)$$

where W is a WHITTAKER FUNCTION, which is given by

$$\frac{d}{z\,dz}\left[\frac{d(wz^{1/2})}{z\,dz}\right] + \left(-\frac{1}{4} + \frac{2k}{z^2} + \frac{3}{4z^4}\right) wz^{1/2} = 0 \quad (2)$$

$$\frac{d^2w}{dz^2} + \left(2k - \tfrac{1}{4}z^2\right) w = 0 \quad (3)$$

(Moon and Spencer 1961, p. 153; Zwillinger 1997, p. 128). This is usually rewritten

$$\frac{d^2 D_n(z)}{dz^2} + \left(n + \tfrac{1}{2} - \tfrac{1}{4}z^2\right) D_n(z) = 0. \quad (4)$$

The solutions are PARABOLIC CYLINDER FUNCTIONS.

The equations

$$\frac{d^2U}{du^2} - (c + k^2u^2)U = 0 \quad (5)$$

$$\frac{d^2V}{du^2} - (c - k^2v^2)V = 0, \quad (6)$$

which arise by separating variables in LAPLACE'S EQUATION in PARABOLIC CYLINDRICAL COORDINATES, are also known as the Weber differential equations. As above, the solutions are known as PARABOLIC CYLINDER FUNCTIONS.

Zwillinger (1997, p. 127) calls

$$y^n + \frac{y'}{x} + \left(1 - \frac{v^2}{x^2}\right) y = -\frac{1}{\pi x^2}[x + v + (x - v)\cos(v\pi)] \quad (7)$$

the Weber differential equation (Gradshteyn and Ryzhik 2000, p. 989).

Weber Functions

Although BESSEL FUNCTIONS OF THE SECOND KIND are sometimes called Weber functions, Abramowitz and Stegun (1972) define a separate Weber function as

$$\mathscr{E}_v(z) = \frac{1}{\pi}\int_0^\pi \sin(v\theta - z\sin\theta)\,d\theta. \quad (1)$$

Letting $\zeta_n = e^{2\pi i/n}$ be a ROOT OF UNITY, another set of Weber functions is defined as

$$f(z) = \frac{\eta\left(\tfrac{1}{2}(z+1)\right)}{\zeta_{48}\eta(z)} \quad (2)$$

$$f_1(z) = \frac{\eta\left(\tfrac{1}{2}z\right)}{\eta(z)} \quad (3)$$

$$f_2(z) = \sqrt{2}\frac{\eta(2z)}{\eta(z)} \quad (4)$$

$$\gamma_2 = \frac{f^{24}(z) - 16}{f^8(z)} \quad (5)$$

$$\gamma_3 = \frac{[f^{24}(z) + 8][f_1^8(z) - f_2^8(z)]}{f^8(z)} \quad (6)$$

(Weber 1902, Atkin and Morain 1993), where $\eta(z)$ is the DEDEKIND ETA FUNCTION. The Weber functions satisfy the identities

$$f(z+1) = \frac{f_1(z)}{\zeta_{48}} \quad (7)$$

$$f_1(z+1) = \frac{f(z)}{\zeta_{48}} \quad (8)$$

$$f_2(z+1) = \zeta_{24} f_2(z) \quad (9)$$

$$f\left(-\frac{1}{z}\right) = f(z) \quad (10)$$

$$f_1\left(-\frac{1}{z}\right) = f_2(z) \quad (11)$$

$$f_2\left(-\frac{1}{z}\right) = f_1(z) \quad (12)$$

(Weber 1902, Atkin and Morain 1993).

Wedderburn's Theorem

A FINITE DIVISION RING is a FIELD.

Weddle's Rule

Let the values of a function $f(x)$ be tabulated at points x_i equally spaced by $h = x_{i+1} - x_i$, so $f_1 = f(x_1)$, $f_2 = f(x_2)$, ..., $f_7 = f(x_7)$. Then Weddle's rule approximating the integral of $f(x)$ is given by the NEWTON-COTES-like formula

$$\int_{x_1}^{x_{6n}} f(x)\,dx = \tfrac{3}{10}h(f_1 + 5f_2 + f_3 + 6f_4 + 5f_5 + f_6 + \ldots + 5f_{6n-1} + f_{6n})$$

Wedge

The term "wedge" has a number of meanings in mathematics. It is sometimes used as another name for the CARET symbol, as well as being the notation ($\wedge$) for logical AND.

In SOLID GEOMETRY, a wedge is a right triangular PRISM turned so that it rests on one of its lateral rectangular faces (left figure). Harris and Stocker (1998) define a more general type of wedge in which the top edge is symmetrically shortened, causing the end triangles to slant obliquely (right figure).

For a wedge of base lengths a and b, height h, and top edge length c, the VOLUME of the wedge is

$$V = \tfrac{1}{6}h(2a + c).$$

In the case $c = a$, this simplifies to $V = ha/2$. The CENTROID is located at a height

$$\bar{z} = \frac{(a+c)h}{2(2a+c)}$$

above the base, which simplifies to h^3 for $c = a$.

Wedge Product

The wedge product is the product in an EXTERIOR ALGEBRA. If α and β are DIFFERENTIAL K-FORMS of degrees p and q, respectively, then

$$\alpha\wedge\beta = (-1)^{pq}\beta\wedge\alpha. \tag{1}$$

It is not (in general) COMMUTATIVE, but it is ASSOCIATIVE,

$$(\alpha\wedge\beta)\wedge u = \alpha\wedge(\beta\wedge u), \tag{2}$$

and BILINEAR

$$(c_1\alpha_1 + c_2\alpha_2)\wedge\beta = c_1(\alpha_1\wedge\beta) + c_2(\alpha_2\wedge\beta) \tag{3}$$

$$\alpha\wedge(c_1\beta_1 + c_2\beta_2) = c_1(\alpha\wedge\beta_1) + c_2(\alpha\wedge\beta_2) \tag{4}$$

(Spivak 1999, p. 203), where c_1 and c_2 are constants. The alternating algebra is generated by elements of degree one, and so the wedge product can be defined using a basis e_i for V:

$$\left(e_{i_1}\wedge\ldots\wedge e_{i_p}\right)\wedge\left(e_{j_1}\wedge\ldots\wedge e_{j_q}\right) = e_{i_1}\wedge\ldots\wedge e_{i_p} \wedge e_{j_1}\wedge\ldots\wedge e_{j_q} \tag{5}$$

when the indices $i_1,\ldots,i_p, i_1,\ldots,i_q$ are distinct, and the product is zero otherwise.

While the formula $\alpha\wedge\alpha = 0$ holds when α has degree one, it does not hold in general. For example, consider $\alpha = e_1\wedge e_2 + e_3\wedge e_4$:

$$\begin{aligned}\alpha\wedge\alpha &= (e_1\wedge e_2)\wedge(e_1\wedge e_2) + (e_1\wedge e_2)\wedge(e_3\wedge e_4)\\ &\quad+(e_3\wedge e_4)\wedge(e_1\wedge e_2) + (e_3\wedge e_4)\wedge(e_3\wedge e_4)\\ &= 0 + e_1\wedge e_2\wedge e_3\wedge e_4 + e_3\wedge e_4\wedge e_1\wedge e_2 + 0\\ &= 2e_1\wedge e_2\wedge e_3\wedge e_4\end{aligned} \tag{6}$$

If $\alpha_1,\ldots,\alpha_k$ have degree one, then they are linearly independent IFF $\alpha_1\wedge\ldots\wedge\alpha_k \neq 0$.

The wedge product is the "correct" type of product to use in computing a VOLUME ELEMENT

$$dV = dx_1\wedge\ldots\wedge dx_n. \tag{7}$$

The wedge product can therefore be used to calculate DETERMINANTS and volumes of PARALLELEPIPEDS. For example, write $\det A = \det(c_1,\ldots,c_n)$ where c_i are the columns of A. Then

$$c_1\wedge\ldots\wedge c_n = \det(c_1,\ldots,c_n)e_1\wedge\ldots\wedge e_n \tag{8}$$

and $|\det(c_1,\ldots,c_n)|$ is the volume of the PARALLELEPIPED spanned by $c_1,\ldots,c_n$.

In *Mathematica*, a k-form can be written as an ANTISYMMETRIC k-tensor. Using this format, the following *Mathematica* function computes the wedge product. vars.

```
Alt[x_List] := Module[
   {
   p = TensorRank[x],   perms
   },
   perms = Permutations[Range[p]];
      Sum[Signature[perms[[i]]]  Transpose[x,
perms[[i]]],{i, p!}]/p!
 ] Wedge1[a_List, b_List] := Alt[Outer[Times,
a, b]]
```

It is also possible to use an n-nested binary tree to represent the algebra of differential forms. Using this format, the following *Mathematica* function computes the wedge product recursively.

```
Wedge2[{a_?(! ListQ[#1] &), b_?(! ListQ[#1]
&)}, {c_?(! ListQ[#1] &), d_?(! ListQ[#1]
&)}] := {a d + b c, b d} sgn2[a_?ListQ] :=
MapIndexed[(Times[#1, Power[-1, Tr[#2]]] &),
a, {TensorRank[a]}]; Wedge2[{a_List, b_List},
{c_List, d_List}] :=
     {Wedge2[a, d] + Wedge2[sgn2[b], c],
Wedge2[b, d]}
```

Weibull Distribution

The Weibull distribution is given by

$$P(x) = \alpha\beta^{-\alpha}x^{\alpha-1}e^{-(x/\beta)^\alpha} \tag{1}$$

$$D(x) = 1 - e^{-(x/\beta)^\alpha} \tag{2}$$

for $x \in [0, \infty)$, and is implemented in *Mathematica* as `WeibullDistribution[`a`, `b`]` in the *Mathematica* add-on package `Statistics`ContinuousDistributions`` (which can be loaded with the command `<<Statistics``). The RAW MOMENTS of the distribution are

$$\mu_1' = b\Gamma(1+\alpha^{-1}) \tag{3}$$

$$\mu_2' = b^2\Gamma(1+2\alpha^{-1}) \tag{4}$$

$$\mu_3' = b^3\Gamma(1+3\alpha^{-1}) \tag{5}$$

$$\mu_4' = b^4\Gamma(1+4\alpha^{-1}), \tag{6}$$

and the MEAN, VARIANCE, SKEWNESS, and KURTOSIS of are

$$\mu = \beta\Gamma(1+\alpha^{-1}) \tag{7}$$

$$\sigma^2 = \beta^2[\Gamma(1+2\alpha^{-1}) - \Gamma^2(1+\alpha^{-1})] \tag{8}$$

$$\gamma_1 = \frac{2\Gamma^3(1+\alpha^{-1}) - 3\Gamma(1+\alpha^{-1})\Gamma(1+2\alpha^{-1})}{[\Gamma(1+2\alpha^{-1}) - \Gamma^2(1+\alpha^{-1})]^{3/2}} + \frac{\Gamma(1+3\alpha^{-1})}{[\Gamma(1+2\alpha^{-1}) - \Gamma^2(1+\alpha^{-1})]^{3/2}} \tag{9}$$

$$\gamma_2 = \frac{f(a)}{[\Gamma(1+2\alpha^{-1}) - \Gamma^2(1+\alpha^{-1})]^2}, \tag{10}$$

where $\Gamma(z)$ is the GAMMA FUNCTION and

$$f(a) \equiv -6\Gamma^4(1+\alpha^{-1}) + 12\Gamma^4(1+\alpha^{-1})\Gamma(1+2\alpha^{-1}) - 3\Gamma^2(1+2\alpha^{-1}) - 4\Gamma(1+\alpha^{-1})\Gamma(1+3\alpha^{-1}) + \Gamma(1+4\alpha^{-1}). \tag{11}$$

A slightly different form of the distribution is defined by

$$P(x) = \frac{\alpha}{\beta}x^{\alpha-1}e^{-x^\alpha/\beta} \tag{12}$$

$$D(x) = 1 - e^{-x^\alpha/\beta} \tag{13}$$

(Mendenhall and Sincich 1995). This has RAW MOMENTS

$$\mu_1 = \beta^{1/\alpha}\Gamma(1+\alpha^{-1}) \tag{14}$$

$$\mu_2 = \beta^{2/\alpha}\Gamma(1+2\alpha^{-1}) \tag{15}$$

$$\mu_3 = \beta^{3/\alpha}\Gamma(1+3\alpha^{-1}) \tag{16}$$

$$\mu_4 = \beta^{4/\alpha}\Gamma(1+4\alpha^{-1}) \tag{17}$$

so the MEAN and VARIANCE for this form are

$$\mu = \beta^{1/\alpha}\Gamma(1+\alpha^{-1}) \tag{18}$$

$$\sigma^2 = \beta^{2/\alpha}[\Gamma(1+2\alpha^{-1}) - \Gamma^2(1+\alpha^{-1})] \tag{19}$$

The Weibull distribution gives the distribution of lifetimes of objects. It was originally proposed to quantify fatigue data, but it is also used in analysis of systems involving a "weakest link."

Weierstrass Approximation Theorem

If f is a continuous real-valued function on $[a, b]$ and if any $\epsilon > 0$ is given, then there exists a POLYNOMIAL p on $[a, b]$ such that

$$|f(x) - P(x)| < \epsilon$$

for all $x \in [a, b]$. In words, any continuous function on a closed and bounded interval can be uniformly approximated on that interval by POLYNOMIALS to any degree of accuracy.

Weierstrass Elliptic Function

The Weierstrass elliptic functions (or Weierstrass $\wp$-functions, voiced "p-functions") are elliptic functions which, unlike the JACOBI ELLIPTIC FUNCTIONS, have a second-order POLE at $z=0$. The above plots show the Weierstrass elliptic function $\wp(z)$ and its derivative $\wp'(z)$ for invariants (defined below) of $g_2=0$ and $g_3=0$. The Weierstrass elliptic function is implemented in *Mathematica* as `WeierstrassP[u, {g1, g2}]`.

The plots above show the derivatives of the Weierstrass $\wp$-function.

Weierstrass elliptic functions are denoted $\wp(z)$ and can be defined by

$$\wp(z)=\frac{1}{z^2}+\sum_{m,n=-\infty}^{\infty}{}'\left[\frac{1}{(z-2m\omega_1-2n\omega_2)^2}-\frac{1}{(2m\omega_1+2n\omega_2)^2}\right] \tag{1}$$

(Whittaker and Watson 1990, p. 434). Write $\Omega_{mn}\equiv 2m\omega_1+2n\omega_2$. Then this can be written

$$\wp(z)=z^{-2}+\sum_{m,n}{}'\left[(z-\Omega_{mn})^{-2}-\Omega_{mn}^{-2}\right]. \tag{2}$$

An equivalent definition which converges more rapidly is

$$\wp(z)=\left(\frac{\pi}{2\omega_1}\right)^2\left[-\frac{1}{3}+\sum_{n=-\infty}^{\infty}\csc^2\left(\frac{z-2n\omega_2}{2\omega_1}\pi\right)\right.$$

$$\left.-\sum_{n=-\infty}^{\infty}{}'\csc^2\left(\frac{n\omega_2}{\omega_1}\pi\right)\right] \tag{3}$$

(Whittaker and Watson 1990, p. 434). $\wp(z)$ is an EVEN FUNCTION since $\wp(-z)$ gives the same terms in a different order. To specify $\wp$ completely, its periods or invariants, written $\wp(z|\omega_1,\omega_2)$ and $\wp(z;g_1,g_2)$, respectively, must also be specified.

The series expansion of $\wp(z)$ is given by

$$\wp(z)=z^{-2}-\sum_{k=2}^{\infty}c_k z^{2k-2}, \tag{4}$$

where

$$c_2=\frac{g_2}{20} \tag{5}$$

$$c_3=\frac{g_3}{28} \tag{6}$$

and

$$c_k = \frac{3}{(2k+1)(k-3)} \sum_{m=2}^{k-2} c_m c_{k-m} \qquad (7)$$

for $k \geq 4$ (Abramowitz and Stegun 1972, p. 635). The first few values for c_k for $k \geq 4$ in terms of c_2 and c_3 are given by

$$c_4 = \tfrac{1}{3} c_2^2 \qquad (8)$$

$$c_5 = \tfrac{1}{11}(3c_2c_3) \qquad (9)$$

$$c_6 = \tfrac{1}{39}(2c_2^3 + 3c_3^2) \qquad (10)$$

$$c_7 = \tfrac{2}{33} 2c_2^2 c_3 \qquad (11)$$

$$c_8 = \tfrac{5}{7293}(11c_2^4 + 36c_2c_3^2) \qquad (12)$$

$$c_9 = \tfrac{29}{2717}(c_2^3 c_3 + 11c_3^2) \qquad (13)$$

$$c_{10} = \tfrac{1}{240669}(242c_2^5 + 1455c_2^2c_3^2) \qquad (14)$$

(Abramowitz and Stegun 1972, p. 636).

The Weierstrass elliptic function describes how to get from a TORUS giving the solutions of an ELLIPTIC CURVE to the algebraic form of the ELLIPTIC CURVE.

The differential equation from which Weierstrass elliptic functions arise can be found by expanding about the origin the function $f(z) \equiv \wp(z) - z^{-2}$.

$$\wp(z) - z^{-2} = f(0) + f'(0)z + \frac{1}{2!} f''(0)z^2 + \frac{1}{3!} f'''(0)z^3 + \frac{1}{4} f^{(4)}(0)z^4 + \ldots. \qquad (15)$$

But $f(0) = 0$ and the function is even, so $f'(0) = f'''(0) = 0$ and

$$f(z) = \wp(z) - z^{-2} = \frac{1}{2!} f''(0)z^2 + \frac{1}{4} f^{(4)}(0)z^4 + \ldots. \qquad (16)$$

Taking the derivatives

$$f' = -2\Sigma'(z - \Omega_{mn})^{-3} \qquad (17)$$

$$f'' = 6\Sigma'(z - \Omega_{mn})^{-4} \qquad (18)$$

$$f''' = -24\Sigma'(z - \Omega_{mn})^{-5} \qquad (19)$$

$$f^{(4)} = 120\Sigma'(z - \Omega_{mn})^{-6}. \qquad (20)$$

So

$$f''(0) = 6\Sigma'\Omega_{mn}^{-4} \qquad (21)$$

$$f^{(4)}(0) = 120\Sigma'\Omega_{mn}^{-6}. \qquad (22)$$

Plugging in,

$$\wp(z) - z^{-2} = 3\Sigma'\Omega_{mn}^{-4} z^2 + 5\Sigma'\Omega_{mn}^{-6} z^4 + \mathcal{O}(z^6) \qquad (23)$$

Define the INVARIANTS

$$g_2 \equiv 60\Sigma'\Omega_{mn}^{-4} \qquad (24)$$

$$g_3 \equiv 140\Sigma'\Omega_{mn}^{-6}, \qquad (25)$$

then

$$\wp(z) = z^{-2} + \tfrac{1}{20} g_2 z^2 + \tfrac{1}{28} g_3 z^4 + \mathcal{O}(z^6) \qquad (26)$$

$$\wp'(z) = -2z^{-3} + \tfrac{1}{10} g_2 z + \tfrac{1}{7} g_3 z^3 + \mathcal{O}(z^5). \qquad (27)$$

Now cube (26) and square (27)

$$\wp^3(z) = z^{-6} + \tfrac{3}{20} g_2 z^{-2} + \tfrac{3}{28} g_3 + \mathcal{O}(z^2) \qquad (28)$$

$$\wp'^2(z) = 4z^{-6} - \tfrac{2}{5} g_2 z^{-2} - \tfrac{4}{7} g_3 + \mathcal{O}(z^2). \qquad (29)$$

Taking (29) minus 4× (28) cancels out the z^{-6} term, giving

$$\wp'^2(z) - 4\wp^3(z) = \left(-\tfrac{2}{5} - \tfrac{3}{5}\right) g_2 z^{-2} + \left(-\tfrac{4}{7} - \tfrac{3}{7}\right) g_3 + \mathcal{O}(z^2)$$
$$= -g_2 z^{-2} - g_3 + \mathcal{O}(z^2) \qquad (30)$$

$$\wp'^2(z) - 4\wp^3(z) + g_2 z^{-2} + g_3 = \mathcal{O}(z^2). \qquad (31)$$

But, from (16)

$$\wp(z) = z^{-2} + \tfrac{1}{2!} f''(0)z^2 + \tfrac{1}{4} f^{(4)}(0)z^4 + \ldots, \qquad (32)$$

so $\wp(z) = z^{-2} + \mathcal{O}(z^2)$ and (31) can be written

$$\wp'^2(z) - 4\wp^3(z) + g_2\wp(z) + g_3 = \mathcal{O}(z^2). \qquad (33)$$

But the Weierstrass elliptic function is analytic at the origin and therefore at all points congruent to the origin. There are no other places where a singularity can occur, so this function is an ELLIPTIC FUNCTION with no SINGULARITIES. By LIOUVILLE'S ELLIPTIC FUNCTION THEOREM, it is therefore a constant. But as $z \to 0$, $\mathcal{O}(z^2) \to 0$, so

$$\wp'^2(z) = 4\wp^3(z) - g_2\wp(z) - g_3 \qquad (34)$$

(Whittaker and Watson 1990, pp. 436–37).

The solution to the differential equation

$$y'^2 = 4y^3 - g_2 y - g_3 \qquad (35)$$

is therefore given by $y = \wp(z + \alpha)$, providing that numbers ω_1 and ω_2 exist which satisfy the equations defining the INVARIANTS. Writing the differential equation in terms of its roots e_1, e_2, and e_3,

$$y'^2 = 4y^3 - g_2 y - g_3 = 4(y - e_1)(y - e_2)(y - e_3) \qquad (36)$$

(Rainville 1971, p. 312),

$$2\ln(y') = \ln 4 + \sum_{r=1}^{3} \ln(y - e_r) \qquad (37)$$

$$\frac{2y''}{y'} = y' \sum_{r=1}^{3} (y - e_r)^{-1} \qquad (38)$$

$$\frac{2y''}{y'^2}=\sum_{r=1}^{3}(y-e_r)^{-1} \quad (39)$$

$$2\frac{y'^2y'''-y''(2y'y'')}{y'^4}=-y'\sum_{r=1}^{3}(y-e_r)^{-2} \quad (40)$$

$$\frac{2y'''}{y'^3}-\frac{4y''^2}{y'^4}=-\sum_{r=1}^{3}(y-e_r)^{-2}. \quad (41)$$

Now take (41) divided by 4 plus [(41) divided by 4] quantity squared,

$$\left(\frac{y'''}{2y'^3}-\frac{y''^2}{y'^4}\right)+\left(\frac{y''^2}{4y'^4}\right)$$
$$=-\frac{1}{4}\sum_{r=1}^{3}(y-e_r)^{-2}+\frac{1}{16}\left[\sum_{r=1}^{3}(y-e_r)^{-1}\right]^2 \quad (42)$$

$$\frac{3y''^2}{4y'^4}-\frac{y'''}{2y'^3}=\tfrac{3}{16}\sum_{r=1}^{3}(y-e_r)^{-2}-\tfrac{3}{8}y\prod_{r=1}^{3}(y-e_r)^{-1}. \quad (43)$$

The term on the right is half the SCHWARZIAN DERIVATIVE.

The DERIVATIVE of the Weierstrass elliptic function is given by

$$\wp'(z)=\frac{d}{dz}\wp(z)=-2\sum_{m,n}\frac{1}{(z-\Omega_{mn})^3}$$
$$=-2z^{-3}-2\sum_{m,n}{}'(z-\Omega_{mn})^{-3}. \quad (44)$$

This is an ODD FUNCTION which is itself an elliptic function with pole of order 3 at $z=0$. T he INTEGRAL is given by

$$z=\int_{\wp(z)}^{\infty}(4t^3-g_2t-g_3)^{-1/2}dt. \quad (45)$$

The second derivative satisfies

$$\wp''\left(\tfrac{1}{2}\omega_1\right)=2(e_1-e_2)(e_1-e_3) \quad (46)$$

(Apostol 1997, p. 23).

A duplication formula is obtained as follows.

$$\wp(2z)=\lim_{y\to z}\wp(y+z)$$
$$=\frac{1}{4}\lim_{y\to z}\left[\frac{\wp'(z)-\wp'(y)}{\wp(z)-\wp(y)}\right]^2-\wp(z)-\lim_{y\to z}\wp(y)$$
$$=\frac{1}{4}\lim_{h\to 0}\left[\frac{\wp(z)-\wp'(z+h)}{\wp(z)-\wp(z+h)}\right]^2-2\wp(z)$$
$$=\frac{1}{4}\left\{\left[\lim_{h\to 0}\frac{\wp'(z)-\wp'(z+h)}{h}\right]\right.$$
$$\left.\times\left[\lim_{h\to 0}\frac{h}{\wp(z)-\wp(z+h)}\right]\right\}^2-2\wp(z)$$
$$=\frac{1}{4}\left[\frac{\wp''(z)}{\wp'(z)}\right]^2-2\wp(z) \quad (47)$$

(Apostol 1997, p. 24).

A general addition theorem is obtained as follows. Given

$$\wp'(z)=A\wp(z)+B \quad (48)$$

$$\wp'(y)=A\wp(y)+B \quad (49)$$

with zero y and z where $z\not\equiv\pm y(\mathrm{mod}\ 2\omega_1, 2\omega_2)$, find the third zero ζ. Consider $\wp'(\zeta)-A\wp(\zeta)-B$. This has a pole of order three at $\zeta=0$, but the sum of zeros $(=0)$ equals the sum of poles for an ELLIPTIC FUNCTION, so $z+y+\zeta=0$ and $\zeta=-z-y$.

$$\wp'(-z-y)=A\wp(-z-y)+B \quad (50)$$

$$-\wp'(z+y)=A\wp(z+y)+B. \quad (51)$$

Combining (48), (49), and (51) gives

$$\begin{bmatrix}\wp(z) & \wp'(z) & 1\\ \wp(y) & \wp'(y) & 1\\ \wp(z+y) & -\wp(z+y) & 1\end{bmatrix}\begin{bmatrix}A\\ -1\\ B\end{bmatrix}=\begin{bmatrix}0\\0\\0\end{bmatrix}, \quad (52)$$

so

$$\begin{vmatrix}\wp(z) & \wp'(z) & 1\\ \wp(y) & \wp'(y) & 1\\ \wp(z+y) & -\wp(z+y) & 1\end{vmatrix}=0. \quad (53)$$

Defining $u+v+w=0$ where $u\equiv z$ and $v\equiv y$ gives the symmetric form

$$\begin{vmatrix}\wp(u) & \wp'(u) & 1\\ \wp(v) & \wp'(v) & 1\\ \wp(w) & \wp(w) & 1\end{vmatrix}=0 \quad (54)$$

(Whittaker and Watson 1990, p. 440). To get the expression explicitly, start again with

$$\wp'(\zeta)-A\wp(\zeta)-B=0, \quad (55)$$

where $\zeta=z, y, -z-y$.

$$\wp'^2(\zeta)-[A\wp(\zeta)+B]^2=0. \quad (56)$$

But from (34), $\wp'^2(\zeta)=4\wp^3(\zeta)-g_2\wp(\zeta)-g_3$, so

$$4\wp^3(\zeta)-A^2\wp^2(\zeta)-(2AB+g_2)\wp(\zeta)-(B^2+g_3)=0. \quad (57)$$

The solutions $\wp(\zeta)\equiv z$ are given by

$$4z^3-A^2z^2-(2AB+g_2)z-(B^2+g_3)=0. \quad (58)$$

But the sum of roots equals the COEFFICIENT of the squared term, so

$$\wp(z)+\wp(y)+\wp(z+y)=\tfrac{1}{4}A^2 \quad (59)$$

$$\wp'(z) - \wp'(y) = A[\wp(z) - \wp(y)] \tag{60}$$

$$A = \frac{\wp'(z) - \wp'(y)}{\wp(z) - \wp(y)} \tag{61}$$

$$\wp(z+y) = \frac{1}{4}\left[\frac{\wp'(z) - \wp'(y)}{\wp(z) - \wp(y)}\right]^2 - \wp(z) - \wp(y) \tag{62}$$

(Whittaker and Watson 1990, p. 441).

Half-period identities include

$$x \equiv \wp\left(\tfrac{1}{2}\omega_1\right) = \wp(-h\omega_1 + \omega_1) = e_1 + \frac{(e_1 - e_2)(e_1 - e_3)}{\wp\left(-\tfrac{1}{2}\omega_1\right) - e_1}$$

$$= e_1 + \frac{(e_1 - e_2)(e_1 - e_3)}{x - e_1}. \tag{63}$$

Multiplying through,

$$x^2 - e_1 x = e_1 x - e_1^2 + (e_1 - e_2)(e_1 - e_3) \tag{64}$$

$$x^2 - 2e_1 + \left[e_1^2 - (e_1 - e_2)(e_1 - e_3)\right] = 0, \tag{65}$$

which gives

$$\wp\left(\tfrac{1}{2}\omega_1\right) = \tfrac{1}{2}\left\{2e_1 \pm \sqrt{4e_1^2 - 4[e_1^2 - (e_1 - e_2)(e_1 - e_3)]}\right\}$$

$$= e_1 \pm \sqrt{(e_1 - e_2)(e_1 - e_3)}. \tag{66}$$

From Whittaker and Watson (1990, p. 445),

$$\wp'\left(\tfrac{1}{2}\omega_1\right) = -2\sqrt{(e_1 - e_2)(e_1 - e_3)} \times \left(\sqrt{e_1 - e_2} + \sqrt{e_1 - e_3}\right). \tag{67}$$

The function is HOMOGENEOUS,

$$\wp(\lambda z|\lambda\omega_1, \lambda\omega_2) = \lambda^{-2}\wp(z|\omega_1, \omega_2) \tag{68}$$

$$\wp\left(\lambda z; \lambda^{-4}g_2, \lambda^{-6}g_3\right) = \lambda^{-2}\wp(z; g_2, g_3). \tag{69}$$

To invert the function, find $2\omega_1$ and $2\omega_2$ of $\wp(z|\omega_1, \omega_2)$ when given $\wp(z; g_1, g_2)$. Let e_1, e_2, and e_3 be the roots such that $(e_1 - e_2)/(e_1 - e_3)$ is not a REAL NUMBER > 1 or < 0. Determine the PARAMETER τ from

$$\frac{e_1 - e_2}{e_1 - e_3} = \frac{\vartheta_4^4(0|\tau)}{\vartheta_3^4(0|\tau)}. \tag{70}$$

Now pick

$$A \equiv \frac{\sqrt{e_1 - e_2}}{\vartheta_4^2(0|\tau)}. \tag{71}$$

As long as $g_2^3 \neq 27g_3$, the periods are then

$$2\omega_1 = \pi A \tag{72}$$

$$2\omega_2 = \frac{\pi\tau}{A}. \tag{73}$$

Weierstrass elliptic functions can be expressed in terms of JACOBI ELLIPTIC FUNCTIONS by

$$\wp(u; g_2, g_3) = e_3 + (e_1 - e_3)\,\mathrm{ns}^2\left(u\sqrt{e_1 - e_3}, \sqrt{\frac{e_2 - e_3}{e_1 - e_3}}\right), \tag{74}$$

where

$$\wp(\omega_1) = e_1 \tag{75}$$

$$\wp(\omega_2) = e_2 \tag{76}$$

$$\wp(\omega_3) = -\wp(-\omega_1 - \omega_2) = e_3, \tag{77}$$

and the INVARIANTS are

$$g_2 \equiv 60 \sum_{m,n}{}' \Omega_{mn}^{-4} \tag{78}$$

$$g_3 \equiv 140 \sum_{m,n}{}' \Omega_{mn}^{-6}. \tag{79}$$

Here, $\Omega_{mn} \equiv 2m\omega_1 - 2n\omega_2$.

An addition formula for the Weierstrass elliptic function can be derived as follows.

$$\wp(z + \omega_1) + \wp(z) + \wp(\omega_1) = \frac{1}{4}\left[\frac{\wp'(z) - \wp'(\omega_1)}{\wp(z) - \wp(\omega_1)}\right]^2 = \frac{1}{4}\frac{\wp'^2(z)}{[\wp(z) - e_1]^2}. \tag{80}$$

Use

$$\wp'(z) = 4\prod_{r=1}^{3}[\wp(z) - e_r], \tag{81}$$

so

$$\wp(z + \omega_1) = -\wp(z) - e_1 + \frac{1}{4}\frac{4\prod_{r=1}^{3}[\wp(z) - e_r]}{[\wp(z) - e_1]^2}$$

$$= -\wp(z) - e_1 + \frac{[\wp(z) - e_2][\wp(z) - e_3]}{\wp(z) - e_1}. \tag{82}$$

Use $\Sigma_{r=1}^{3} e_r = 0$,

$$\wp(z + \omega_1) = e_1 + \frac{[-2e_1 - \wp(z)][\wp(z) - e_1]}{\wp(z) - e_1} + \frac{\wp^2(z) - \wp(z)(e_2 + e_3) + e_2 e_3}{\wp(z) - e_1}$$

$$= e_1 + \frac{-\wp(z)(e_1 + e_2 + e_3) + e_2 e_3 + 2e_1^2}{\wp(z) - e_1}. \tag{83}$$

But $\Sigma_{r=1}^{3} e_r = 0$ and

$$2e_1^2 + e_2 e_3 = e_1^2 - e_1(e_2 + e_3) + e_2 e_3 = (e_1 - e_2)(e_1 - e_3), \tag{84}$$

so

$$\wp(z+\omega_1) = e_1 + \frac{(e_1 - e_2)(e_1 - e_3)}{\wp(z) - e_1}. \quad (85)$$

The periods of the Weierstrass elliptic function are given as follows. When g_2 and g_3 are REAL and $g_2^3 - 27g_3^2 > 0$, then e_1, e_2, and e_3 are REAL and defined such that $e_1 > e_2 > e_3$.

$$\omega_1 = \int_{e_1}^{\infty} \left(4t^3 - g_2 t - g_3\right)^{-1/2} dt \quad (86)$$

$$\omega_3 = -i\int_{-\infty}^{e_3} \left(g_3 + g_2 t - 4t^3\right)^{-1/2} dt \quad (87)$$

$$\omega_2 = -\omega_1 - \omega_3. \quad (88)$$

The roots of the Weierstrass elliptic function satisfy

$$e_1 = \wp(\omega_1) \quad (89)$$

$$e_2 = \wp(\omega_2) \quad (90)$$

$$e_3 = \wp(\omega_3), \quad (91)$$

where $\omega_3 \equiv -\omega_1 - \omega_2$. The e_is are ROOTS of $4t^3 - g_2 t - g_3$ and are unequal so that $e_1 \neq e_2 \neq e_3$.. They can be found from the relationships

$$e_1 + e_2 + e_3 = -a_2 = 0 \quad (92)$$

$$e_2 e_3 + e_3 e_1 + e_1 e_2 = a_1 = -\tfrac{1}{4} g_2 \quad (93)$$

$$e_1 e_2 e_3 = -a_0 = \tfrac{1}{4} g_3. \quad (94)$$

Weierstrass Extreme Value Theorem

EXTREME VALUE THEOREM

Weierstrass Factor Theorem

Let any finite or infinite set of points having no finite LIMIT POINT be prescribed, and associate with each of its points a definite positive integer as its order. Then there exists an ENTIRE FUNCTION which has zeros to the prescribed orders at precisely the prescribed points, and is otherwise different from zero. Moreover, this function can be REPRESENTED AS a product from which one can read off again the positions and orders of the zeros. Furthermore, if $G_0(z)$ is one such function, then

$$G(z) = e^{h(z)} G_0(z)$$

is the most general function satisfying the conditions of the problem, where $h(z)$ denotes an arbitrary ENTIRE FUNCTION.

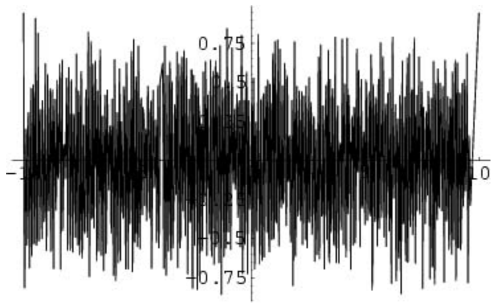
Weierstrass Factorization Theorem

WEIERSTRASS FACTOR THEOREM



Weierstrass Form

A general form into which an ELLIPTIC CURVE over any FIELD K can be transformed is called the Weierstrass form, and is given by

$$y^2 + ay = x^3 + bx^2 + cxy + dx + e,$$

where a, b, c, d, and e are elements of K.

Weierstrass Function

A CONTINUOUS FUNCTION which is nowhere DIFFERENTIABLE. It is given by

$$f(x)=\sum_{n=1}^{\infty} b^n \cos(a^n \pi x)$$

where a is an ODD NUMBER, $b\in(0,1)$, and $ab>1+3\pi/2$. The above plot is for $a=19$ and $b=1/2$.

Weierstrass Intermediate Value Theorem

If a continuous function defined on an interval is sometimes POSITIVE and sometimes NEGATIVE, it must be 0 at some point.

Weierstrass M-Test

Let $\Sigma_{k=1}^{\infty} u_n(x)$ be a SERIES of functions all defined for a set E of values of x. If there is a CONVERGENT series of constants

$$\sum_{n=1}^{\infty} M_n,$$

such that

$$|u_n(x)|\leq M_n$$

for all $x\in E$, then the series exhibits ABSOLUTE CONVERGENCE for each $x\in E$ as well as UNIFORM CONVERGENCE in E.

See also ABSOLUTE CONVERGENCE, UNIFORM CONVERGENCE

Weierstrass Sigma Function

The QUASIPERIODIC FUNCTION defined by

$$\frac{d}{dz}\ln\sigma(z)=\zeta(z), \tag{1}$$

where $\zeta(z)$ is the WEIERSTRASS ZETA FUNCTION and

$$\lim_{z\to\infty}\frac{\sigma(z)}{z}=1. \quad (2)$$

Then

$$\sigma(z)=z\prod_{m,n=-\infty}^{\infty}{}'\left[\left(1-\frac{z}{\Omega_{mn}}\right)\exp\left(\frac{z}{\Omega_{mn}}+\frac{z^2}{2\Omega_{mn}^2}\right)\right], \quad (3)$$

where the term with $m=n=0$ is omitted from the product. In addition, $\sigma(z)$ satisfies

$$\sigma(z+2\omega_1)=-e^{2\eta_1(z+\omega_1)}\sigma(z) \quad (4)$$

$$\sigma(z+2\omega_2)=-e^{2\eta_2(z+\omega_2)}\sigma(z) \quad (5)$$

and

$$\sigma_r(z)=\frac{e^{-\eta_r z}\sigma(z+\omega_r)}{\sigma(\omega_r)} \quad (6)$$

for $r=1, 2, 3$.

$\sigma(z)$ can be expressed in terms of JACOBI THETA FUNCTIONS using the expression

$$\sigma(z|\omega_1,\omega_2)=\frac{2\omega_1}{\pi\vartheta_1'}\exp\left(-\frac{v^2\vartheta_1'''}{6\vartheta_1'}\right)\vartheta_1\left(v\left|\frac{\omega_2}{\omega_1}\right.\right), \quad (7)$$

where $v\equiv \pi z/(2\omega_1)$, and

$$\eta_1=-\frac{\pi^2\vartheta_1'''}{12\omega_1\vartheta_1'} \quad (8)$$

$$\eta_2=-\frac{\pi^2\omega_2\vartheta_1'''}{12\omega_1^2\vartheta_1'}-\frac{\pi i}{2\omega_1}. \quad (9)$$

There is a beautiful series expansion for $\sigma(z)$, given by the DOUBLE SUM

$$\sigma(z)=\sum_{m,n=0}^{\infty}a_{mn}\left(\tfrac{1}{2}g_2\right)^m(2g_3)^n\frac{z^{4m+6n+1}}{(4m+6n+1)!}, \quad (10)$$

where $a_{00}=1$, $a_{mn}=0$ for either subscript negative, and other values are gives by the RECURRENCE RELATION

$$a_{mn}=3(m+1)a_{m+1,n+1}+\tfrac{16}{3}(n+1)a_{m-2,n+1}$$
$$-\tfrac{1}{3}(2m+3n-1)(4m+6n-1)a_{m-1,n} \quad (11)$$

(Abramowitz and Stegun 1972, pp. 635–36). The following table gives the values of the a_{mn} coefficients for small m and n.

	$n=0$	$n=1$	$n=2$	$n=3$
a_{0n}	1	−3	−54	14904
a_{1n}	−1	−18	4968	502200
a_{2n}	−9	513	257580	162100440
a_{3n}	69	33588	20019960	−9465715080
a_{4n}	321	2808945	−376375410	−4582619446320
a_{5n}	160839	−41843142	−210469286736	−1028311276281264

Weierstrass Zeta Function

The QUASIPERIODIC FUNCTION defined by

$$\frac{d\zeta(z)}{dz}\equiv-\wp(z) \quad (1)$$

with

$$\lim_{z\to 0}\left|\zeta(z)-z^{-1}\right|=0. \quad (2)$$

Then

$$\zeta(z)-z^{-1}=-\int_0^z\left[\wp(z)-z^{-2}\right]dz$$

$$=-\Sigma'\int_0^z\left[(z-\Omega_{mn})^{-2}-\Omega_{mn}^{-2}\right]dz \quad (3)$$

$$\zeta(z)=z^{-1}+\sum_{m,n=-\infty}^{\infty}{}'\left[(z-\Omega_{mn})^{-1}+\Omega_{mn}^{-1}+z\Omega_{mn}^{-2}\right] \quad (4)$$

so $\zeta(z)$ is an ODD FUNCTION. Integrating $\wp(z+2\omega_1)=\wp(z)$ gives

$$\zeta(z+2\omega_1)=\zeta(z)+2\eta_1. \quad (5)$$

Letting $z=-\omega_1$ gives $\zeta(-\omega_1)+2\eta_1=-\zeta(\omega_1)+2\eta_1$, so $\eta_1=\zeta(\omega_1)$. Similarly, $\eta_2=\zeta(\omega_2)$. From Whittaker and Watson (1990),

$$\eta_1\omega_2-\eta_2\omega_1=\tfrac{1}{2}\pi i \quad (6)$$

If $x+y+z=0$, then

$$[\zeta(x)+\zeta(y)+\zeta(z)]^2+\zeta'(x)+\zeta'(y)+\zeta'(z)=0 \quad (7)$$

(Whittaker and Watson 1990, p. 446). Also,

$$2\frac{\begin{vmatrix}1 & \wp(x) & \wp^2(x)\\ 1 & \wp(y) & \wp^2(y)\\ 1 & \wp(z) & \wp^2(z)\end{vmatrix}}{\begin{vmatrix}1 & \wp(x) & \wp'(x)\\ 1 & \wp(y) & \wp'(y)\\ 1 & \wp(z) & \wp'(z)\end{vmatrix}} = \zeta(x+y+z)-\zeta(x)-\zeta(y)-\zeta(z) \quad (8)$$

(Whittaker and Watson 1990, p. 446).

The series expansion of $\zeta(z)$ is given by

$$\zeta(z) = z^{-1} - \sum_{k=2}^{\infty} \frac{c_k z^{2k-1}}{2k-1}, \quad (9)$$

where

$$c_2 = \frac{g_2}{20} \quad (10)$$

$$c_3 = \frac{g_3}{28} \quad (11)$$

and

$$c_k = \frac{3}{(2k+1)(k-3)} \sum_{m=2}^{k-2} c_m c_{k-m} \quad (12)$$

for $k \geq 4$ (Abramowitz and Stegun 1972, p. 635).

Weierstrass's Double Series Theorem

Let all of the functions

$$f_n(z) = \sum_{k=0}^{\infty} a_k^{(n)} (z-z_0)^k$$

with $n = 0, 1, 2, ...,$ be regular at least for $|z-z_0| < r$, and let

$$F(z) = \sum_{n=0}^{\infty} f_n(z)$$

$$= [a_0^{(0)} + a_1^{(0)}(z-z_0) + \ldots + a_k^{(0)}(z-z_0)^k + \ldots]$$

$$+ \left[a_0^{(1)} + a_1^{(1)}(z-z_0) + \ldots + a_k^{(1)}(z-z_0)^k + \ldots\right] + \ldots$$

$$+ \left[a_0^{(n)} + a_1^{(n)}(z-z_0) + \ldots + a_k^{(n)}(z-z_0)^k + \ldots\right] + \ldots$$

be uniformly convergent for $z - z_0 \leq \rho < r$ for every $\rho < r$. Then the coefficients in any column form a convergent series. Furthermore, setting

$$a_k^{(0)} + a_k^{(1)} + \ldots + a_k^{(n)} + \ldots = \sum_{n=0}^{\infty} a_k^{(n)} = A_k$$

for $k = 0, 1, 2, ...,$ it then follows that

$$\sum_{k=0}^{\infty} A_k (z-z_0)^k$$

is the POWER SERIES for $F(z)$, which converges at least for $|z-z_0| < r$.

Weierstrass's Gap Theorem

Given a succession of nonsingular points which are on a nonhyperelliptic curve of GENUS p, but are not a group of the canonical series, the number of groups of the first k which cannot constitute the group of simple POLES of a RATIONAL FUNCTION is p. If points next to each other are taken, then the theorem becomes: Given a nonsingular point of a nonhyperelliptic curve of GENUS p, then the orders which it cannot possess as the single pole of a RATIONAL FUNCTION are p in number.

Weierstrass's Theorem

There are at least two theorems known as Weierstrass's theorem. The first states that the only HYPERCOMPLEX NUMBER systems with commutative multiplication and addition are the algebra with one unit such that $e = e^2$ and the GAUSSIAN INTEGERS.

In harmonic analysis, let $U \subseteq \mathbb{C}$ be any OPEN SET, and let a_1, a_2, ..., be a finite or infinite sequence in U (possibly with repetitions) that has no ACCUMULATION POINT in U. There there exists an ANALYTIC FUNCTION f on U whose zero set is precisely $\{a_j\}$ (Krantz 1999, p. 111).

Weighing

n weighings are SUFFICIENT to find a bad COIN among $(3^n - 1)/2$ COINS (Steinhaus 1983, p. 61). vos Savant (1993) gives an algorithm for finding a bad ball among 12 balls in three weighings (which, in addition, determines if the bad ball is heavier or lighter than the other 11), and Steinhaus (1983, pp. 58–1) gives an algorithm for 13 balls.

Bachet's weights problem asks for the *minimum number* of weights (which can be placed in *either* pan of a two-arm balance) required to weigh any integral number of pounds from 1 to 40 (Steinhaus 1983, p. 52). The solution is 1, 3, 9, and 27: 1, $2 = -1+3$, 3, $4 = 1+3$, $5 = -1-3+9$, $6 = -3+9$, $7 = 1-3+9$, $8 = -1+9$, 9, $10 = 1+9$, $11 = -1+3+9$, $12 = 3+9$, $13 = 1+3+9$, $14 = -1-3-9+27$, $15 = -3-9+27$, $16 = 1-3-9+27$, $17 = -1-9+27$, and so on.

Weight

The word weight has many uses in mathematics. It can refer to a function $w(x)$ (also called a WEIGHTING FUNCTION or WEIGHT FUNCTION) used to normalize ORTHOGONAL FUNCTIONS. It can also be used to indicate one of a set of a multiplicative constants placed in front of terms in a MOVING AVERAGE, NEWTON-COTES FORMULAS, edge or vertex of a GRAPH

or TREE, etc. It also refers to the power k in the multiplicative factor $(c\tau+d)^k$ defining a MODULAR FORM.

The weight of a TREE at a point u is the maximum number of edges in any BRANCH at u (Harary 1994, p. 35).

See also MODULAR FORM, MOVING AVERAGE, NEWTON-COTES FORMULAS, WEIGHTED TREE, WEIGHTING FUNCTION

References

Harary, F. *Graph Theory.* Reading, MA: Addison-Wesley, p. 35, 1994.

Weight (Lie Algebra)

Consider a collection of DIAGONAL MATRICES $H_1, \ldots, H_k$, which SPAN a subspace $\mathfrak{h}$. Then the ith EIGENVALUE, i.e., the ith entry along the diagonal, is a LINEAR FUNCTIONAL on $\mathfrak{h}$, and is called a weight.

The general setting for weights occurs in a REPRESENTATION of a SEMISIMPLE LIE ALGEBRA, in which case the CARTAN SUBALGEBRA $\mathfrak{h}$ is ABELIAN and can be put into diagonal form. For example, consider the standard representation of the SPECIAL LINEAR LIE ALGEBRA $\mathfrak{sl}_3(\mathbb{C})$ on $\mathbb{C}^3$. Then

$$H_1 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{bmatrix} \qquad (1)$$

and

$$H_2 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \qquad (2)$$

span the CARTAN SUBALGEBRA $\mathfrak{h}$. There are three weights,

$$\alpha_1(h_{ij}) = h_{11} \qquad (3)$$

$$\alpha_2(h_{ij}) = h_{22} \qquad (4)$$

and

$$\alpha_3(h_{ij}) = h_{33}, \qquad (5)$$

corresponding to the decomposition of

$$\mathbb{C}^3 = \langle e_1 \rangle \oplus \langle e_2 \rangle \oplus \langle e_3 \rangle \qquad (6)$$

into its eigenspaces. Note that $\alpha_1+\alpha_2+\alpha_3=0$, because the matrices have zero TRACE. The eigenvectors e_1, e_2, e_3 are called WEIGHT VECTORS, and the corresponding eigenspaces are called WEIGHT SPACES.

In the important special case of the ADJOINT REPRESENTATION of a SEMISIMPLE LIE ALGEBRA, the weights are called ROOTS and the WEIGHT SPACE is called the ROOT SPACE. The roots generate a DISCRETE LATTICE, called the ROOT LATTICE, in the DUAL SPACE $\mathfrak{h}^*$. The set of all possible weights forms a WEIGHT LATTICE, which contains the ROOT LATTICE. The REPRESENTATIONS of $\mathfrak{g}$ can be classified using the WEIGHT LATTICE.

Weight Function

WEIGHTING FUNCTION

Weighted Graph

A TREE in which each branch is given a numerical WEIGHT. A weighted graph is therefore a special type of LABELED GRAPH in which the labels are numbers (which are usually taken to be positive).

See also LABELED GRAPH, TAYLOR'S CONDITION, WEIGHTED TREE

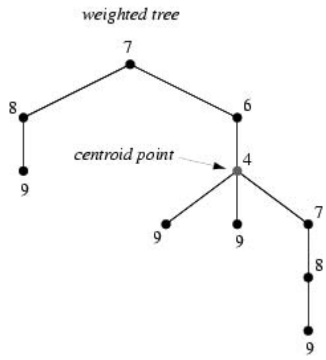
Weighted Inversion Statistic

A STATISTIC w on the SYMMETRIC GROUP S_n is called a weighted inversion statistic if there exists an UPPER TRIANGULAR MATRIX $\mathrm{W} = (w_{ij})$ such that

$$w(\sigma) = \sum_{i<j} \chi(\sigma_i > \sigma_j) w_{ij},$$

where χ is the CHARACTERISTIC FUNCTION.

The inversion count ($w_{ij}=1$ for $i<j$) defined by Cramer (1750) and the major index ($w_{i,i+1}=i$; $w_{ij}=0$ otherwise) defined by MacMahon (1913) are both weighted inversion statistics (Degenhardt and Milne).



See also INVERSION STATISTIC, SYMMETRIC GROUP

MacMahon, P. A. "The Indices of Permutations." *Amer. J. Math.* **35**, 281–22, 1913.

Weighted Tree

A TREE to whose nodes and/or edges labels (usually number) are assigned.

The word "weight" also has a more specific meaning when applied to trees, namely the weight of a TREE at a point u is the maximum number of edges in any BRANCH at u (Harary 1994, p. 35), as illustrated above. A point having minimal weight for the tree is called a CENTROID POINT, and the TREE CENTROID is the set of all CENTROID POINTS.

See also CENTROID POINT, LABELED GRAPH, TAYLOR'S CONDITION, TREE, TREE CENTROID, WEIGHTED GRAPH

Weingarten Equations

The Weingarten equations express the derivatives of the NORMAL to a surface using derivatives of the position vector. Let $\mathbf{x} : U \to \mathbb{R}^3$ be a REGULAR PATCH, then the SHAPE OPERATOR S of $\mathbf{x}$ is given in terms of the basis $\{\mathbf{x}_u, \mathbf{x}_v\}$ by

$$-S(\mathbf{x}_u) = \mathbf{N}_u = \frac{fF - eG}{EG - F^2}\mathbf{x}_u + \frac{eF - fE}{EG - F^2}\mathbf{x}_v \qquad (1)$$

$$-S(\mathbf{x}_v) = \mathbf{N}_v = \frac{gF - fG}{EG - F^2}\mathbf{x}_u + \frac{fF - gE}{EG - F^2}\mathbf{x}_v, \qquad (2)$$

where $\mathbf{N}$ is the NORMAL VECTOR, E, F, and G the coefficients of the first FUNDAMENTAL FORM

$$ds^2 = E\, du^2 + 2F\, du\, dv + G\, dv^2, \qquad (3)$$

and e, f, and g the coefficients of the second FUNDAMENTAL FORM given by

$$e = -\mathbf{N}_u \cdot \mathbf{x}_u = \mathbf{N} \cdot \mathbf{x}_{uu} \qquad (4)$$

$$f = -\mathbf{N}_v \cdot \mathbf{x}_u = \mathbf{N} \cdot \mathbf{x}_{uv}$$

$$= \mathbf{N}_{vu} \cdot \mathbf{x}_{vu} = -\mathbf{N}_u \cdot \mathbf{x}_v \qquad (5)$$

$$g = -\mathbf{N}_v \cdot \mathbf{x}_v = \mathbf{N} \cdot \mathbf{x}_{vv} \qquad (6)$$

SHAPE OPERATOR

Weird Number

A number which is ABUNDANT without being SEMIPERFECT. (A SEMIPERFECT NUMBER is the sum of any set of its own DIVISORS.) The first few weird numbers are 70, 836, 4030, 5830, 7192, 7912, 9272, 10430, ... (Sloane's A006037). No ODD weird numbers are known, but an infinite number of weird numbers are known to exist. The SEQUENCE of weird numbers has POSITIVE SCHNIRELMANN DENSITY.

See also ABUNDANT NUMBER, SCHNIRELMANN DENSITY, SEMIPERFECT NUMBER

Welch Apodization Function

The APODIZATION FUNCTION

$$A(x) = 1 - \frac{x^2}{a^2}.$$

Its FULL WIDTH AT HALF MAXIMUM is $\sqrt{2}a$. Its INSTRUMENT FUNCTION is

$$\begin{aligned} I(k) &= 2a\sqrt{2\pi}\frac{J_{3/2}(2\pi ka)}{(2\pi ka)^{3/2}} \\ &= a\frac{\sin(2\pi ka) - 2\pi ak\cos(2\pi ak)}{2a^3k^3\pi^3}, \end{aligned}$$

where $J_\nu(z)$ is a BESSEL FUNCTION OF THE FIRST KIND. It has a width of 1.59044, a maximum of $\frac{4}{3}$, maximum NEGATIVE sidelobe of -0.0861713 times the peak, and maximum POSITIVE sidelobe of 0.356044 times the peak.

See also APODIZATION FUNCTION, INSTRUMENT FUNCTION

Well Defined

An expression is called "well defined" (or UNAMBIGUOUS) if its definition assigns it a unique interpretation or value. Otherwise, the expression is said to not be well defined or to be AMBIGUOUS.

For example, the expression abc (the PRODUCT) is well defined if a, b, and c are integers. Because integers are ASSOCIATIVE, abc has the same value whether it is interpreted to mean $(ab)c$ or $a(bc)$. However, if a, b, and c are CAYLEY NUMBERS, then the expression abc is *not* well defined, since CAYLEY NUMBER are not, in general, ASSOCIATIVE, so that the two interpretations $(ab)c$ and $a(bc)$ can be different.

Sometimes, ambiguities are implicitly resolved by notational convention. For example, the conventional interpretation of $a \wedge b \wedge c = a^{b^c}$ is $a^{(b^c)}$, never $(a^b)^c$, so that the expression $a \wedge b \wedge c$ is well defined even though exponentiation is nonassociative.

The term "well defined" also has a technical meaning in field of PARTIAL DIFFERENTIAL EQUATIONS. A solution to a PARTIAL DIFFERENTIAL EQUATION that is a continuous function of its values on the boundary is said to be well defined. Otherwise, a solution is called ILL DEFINED.

See also AMBIGUOUS, ILL DEFINED, UNDEFINED

Well Order

WELL ORDERED SET

Well Ordered Set

A TOTALLY ORDERED SET $(A, \leq)$ is said to be well ordered IFF every nonempty SUBSET of A has a least element (Ciesielski 1997, p. 38; Moore 1982, p. 2; Rubin 1967, p. 159; Suppes 1972, p. 75). Every finite TOTALLY ORDERED SET is well ordered. The set of integers $\mathbf{Z}$, which has no least element, is an example of a set that is *not* well ordered.

An ORDINAL NUMBER is the ORDER TYPE of a well ordered set.

Well-Poised

A GENERALIZED HYPERGEOMETRIC FUNCTION

$$ {}_pF_q\left[\begin{matrix}\alpha_1, \alpha_2, \ldots, \alpha_p \\ \beta_1, \beta_2, \ldots, \beta_q\end{matrix}; z\right] $$

is said to be well-poised if $p = q + 1$ and

$$1 + \alpha_1 = \beta_1 + a_2 = \ldots = \beta_q + \alpha_{p+1}$$

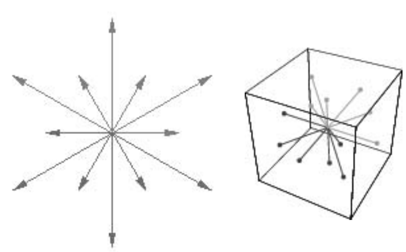
Weyl Character Formula

References



Hsiang, W. Y. "Weyl Character Formula and the Classification of Complex Irreducible Representations." Lec. 4, §4 in *Lectures on Lie Groups.* Singapore: World Scientific, pp. 74–7, 2000.

Weyl Group

Let $\mathscr{L}$ be a finite-dimensional split SEMISIMPLE LIE ALGEBRA over a FIELD of CHARACTERISTIC 0, $\mathscr{H}$ a splitting CARTAN SUBALGEBRA, and Λ a weight of $\mathscr{H}$ in a representation of $\mathscr{L}$. Then

$$\Lambda' = \Lambda S_\alpha = \lambda - \frac{2(\Lambda, \alpha)}{(\alpha, \alpha)}(\alpha)$$

is also a weight. Furthermore, the reflections S_α with α a root, generate a group of linear transformations in $\mathscr{H}_0^*$ called the Weyl group W of $\mathscr{L}$ relative to $\mathscr{H}$, where $\mathscr{H}^*$ is the CONJUGATE SPACE of $\mathscr{H}$ and $\mathscr{H}_0^*$ is the Q-SPACE spanned by the roots (Jacobson 1979, pp. 112, 117, and 119).

The Weyl group acts on the roots of a semisimple Lie algebra, and it is a finite group. The animations above illustrate this action for Weyl Group acting on the roots of a homotopy from one Weyl matrix to the next one (i.e., it slides the arrows from g to h) in the first two figures, while the third figure shows the Weyl Group acting on the roots of the CARTAN MATRIX of the infinite family of semisimple lie algebras A_3 (cf. DYNKIN DIAGRAM), which is the SPECIAL LINEAR LIE ALGEBRA, $\mathfrak{sl}_4$.

Weyl Tensor

The TENSOR C_{abcd} defined by

$$R_{abcd} = C_{abcd} + \frac{2}{n-2}\left(g_{a[c}R_{d]b} - g_{b[c}R_{d]a}\right) - \frac{2}{(n-1)(n-2)} R g_{a[c} g_{d]b}, \tag{1}$$

where R_{abcd} is the RIEMANN TENSOR, R is the SCALAR CURVATURE, g_{ab} is the METRIC TENSOR, and $T_{[a_1 \ldots a_n]}$ denotes the ANTISYMMETRIC TENSOR part (Wald 1984, p. 40).

The Weyl tensor is defined so that every CONTRACTION between indices gives 0. In particular,

$$C^{\lambda}{}_{\mu\lambda\kappa} = 0 \tag{2}$$

(Weinberg 1972, p. 146). The number of independent components for a Weyl tensor in N-D for $N \geq 3$ is given by

$$C_N = \tfrac{1}{12} N(N+1)(N+2)(N-3) \tag{3}$$

(Weinberg 1972, p. 146). For $N = 3$, 4, ..., this gives 0, 10, 35, 84, 168, ... (Sloane's A052472).

Weyl's Criterion

A SEQUENCE $\{x_1, x_2, \ldots\}$ is EQUIDISTRIBUTED IFF

$$\lim_{N\to\infty} \frac{1}{N} \sum_{n<N} e^{2\pi i m x_n} = 0$$

for each $m = 1$, 2, ... A consequence of this result is that the sequence $\{\text{frac}(nx)\}$ is dense and EQUIDISTRIBUTED in the interval $[0, 1]$ for irrational x, where $n = 1$, 2, ... and $\text{frac}(x)$ is the FRACTIONAL PART of x (Finch).

W-Function

LAMBERT'S W-FUNCTION

Wheat and Chessboard Problem

Let one grain of wheat be placed on the first square of a CHESSBOARD, two on the second, four on the third, eight on the fourth, etc. How many grains total are placed on an 8×8 CHESSBOARD? Since this is a GEOMETRIC SERIES, the answer for n squares is

$$\sum_{i=0}^{n-1} 2^i = 2^n - 1,$$

a MERSENNE NUMBER. Plugging in $n = 8 \times 8 = 84$ then gives $2^{64} - 1 - = 18446744073709551615$.

Wheel

ARISTOTLE'S WHEEL PARADOX, BENHAM'S WHEEL, WHEEL GRAPH

Wheel Graph

$\mathbf{W_4}$ $\mathbf{W_5}$ $\mathbf{W_6}$

A GRAPH W_n of order n which contains a CYCLE of order $n-1$, and for which every NODE in the cycle is connected to one other NODE (which is known as the HUB). The edges of a wheel which include the HUB are called spokes (Skiena 1990, p. 146). The wheel W_n can be defined as the graph $K_1 + C_{n-1}$, where K_1 is the (trivial) COMPLETE GRAPH on 1 node and C_n is the CYCLE GRAPH. Wheel graphs can be constructed using `Wheel[n]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`).

In a wheel graph, the HUB has DEGREE $n-1$, and other nodes have degree 3. Wheel graphs are 3-connected. $W_4 = K_4$, where K_4 is the COMPLETE GRAPH of order four. The CHROMATIC NUMBER of W_n is

$$\chi(W_n) = \begin{cases} 4 & \text{for } n \text{ odd} \\ 3 & \text{for } n \text{ even.} \end{cases}$$

Whipple's Identity

Whipple derived a great many identities for GENERALIZED HYPERGEOMETRIC FUNCTIONS, many of which are consequently known as Whipple's identities (transformations, etc.). Among Whipple's identities include

$${}_3F_2\left[\begin{matrix} a, 1-a, c \\ e, 1+2c-e \end{matrix}; 1\right] = \frac{2^{1-2c}\pi\Gamma(e)\Gamma(1+2c-e)}{\Gamma\left[\frac{1}{2}(a+e)\right]\Gamma\left[\frac{1}{2}(a+1+2c-e)\right]}$$

$$\times \frac{1}{\Gamma\left[\frac{1}{2}(1-a+e)\right]\Gamma\left[\frac{1}{2}(2+2c-a-e)\right]}$$

(Bailey 1935, p. 15; Koepf 1998, p. 32), where ${}_3F_2(a,b,c;d,e;z)$ is a GENERALIZED HYPERGEOMETRIC FUNCTION and $\Gamma(z)$ is a GAMMA FUNCTION, and

$${}_6F_5\left[\begin{matrix} a, & 1+\frac{1}{2}a, & b, & c, & d, & e \\ & \frac{1}{2}a, & 1+a-b, & 1-a+c, & 1+a-d, & 1+a-e \end{matrix}; 1\right]$$

$$= \frac{\Gamma(1+a-d)\Gamma(1+a-e)}{\Gamma(1+a)\Gamma(1+a-d-e)}\,{}_3F_2\left[\begin{matrix} 1+a-b-c, d, e; \\ 1+a-b, 1+a-c \end{matrix}\right]$$

(Bailey 1935, p. 28).

See also GENERALIZED HYPERGEOMETRIC FUNCTION, WATSON'S THEOREM

References

Whipple's Transformation

$$ {}_7F_6\left[\begin{matrix} a, 1+\frac{1}{2}a, b, c, d, e, -m \\ \frac{1}{2}a, 1+a-b, 1+a-c, \\ 1+a-d, 1+a-e, 1+a+m \end{matrix}\right] $$

$$ = \frac{(1+a)_m(1+a-d-e)_m}{(1+a-d)_m(1+a-e)_m} $$

$$ \times {}_4F_3\left[\begin{matrix} 1+a-b-c, d, e, -m \\ 1+a-b, 1+a-c, d+e-a-m \end{matrix}\right], $$

where ${}_7F_6$ and ${}_4F_3$ are GENERALIZED HYPERGEOMETRIC FUNCTIONS and $\Gamma(z)$ is the GAMMA FUNCTION.

Another transformation due to Whipple (1926) is given by

$$ {}_4F_3\left[\begin{matrix} a, b, -z, -n \\ u, v, w \end{matrix}; 1\right] $$

$$ = \frac{\Gamma(u+z+n)\Gamma(w+z+n)\Gamma(v)\Gamma(w)}{\Gamma(v+z)\Gamma(v+n)\Gamma(w+n)\Gamma(w+z)} $$

$$ \times {}_4F_3\left[\begin{matrix} u-a, u-b, -z, -n \\ 1-v-z-n, 1-w-z-n, u \end{matrix}; 1\right] \quad (1) $$

for one of z and n a NONNEGATIVE INTEGER (Andrews and Burge 1993).

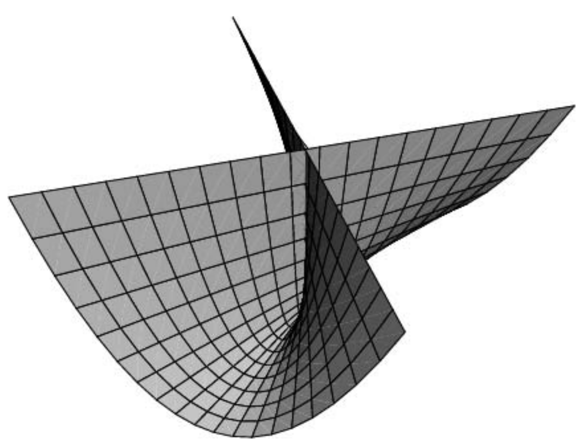
Whitehead's Theorem

MAPS between CW-COMPLEXES that induce ISOMORPHISMS on all HOMOTOPY GROUPS are actually HOMOTOPY equivalences.

See also CW-COMPLEX, HOMOTOPY GROUP, ISOMORPHISM

Whitney Singularity

PINCH POINT



Whitney Sum

An operation that takes two VECTOR BUNDLES over a fixed SPACE and produces a new VECTOR BUNDLE over the same SPACE. If E_1 and E_2 are VECTOR BUNDLES over B, then the Whitney sum $E_1 \oplus E_2$ is the VECTOR BUNDLE over B such that each FIBER over B is naturally the DIRECT SUM of the E_1 and E_2 FIBERS over B.

The Whitney sum is therefore the FIBER for FIBER DIRECT SUM of the two BUNDLES E_1 and E_2. An easy formal definition of the Whitney sum is that $E_1 \oplus E_2$ is the pull-back BUNDLE of the diagonal map from B to $B \times B$, where the BUNDLE over $B \times B$ is $E_1 \times E_2$.

See also BUNDLE, FIBER, VECTOR BUNDLE

Whitney Umbrella

A surface which can be interpreted as a self-intersecting RECTANGLE in 3-D. It is given by the parametric equations

$$x = uv \quad (1)$$

$$y = u \quad (2)$$

$$z = v^2 \quad (3)$$

for $u, v \in [-1, 1]$. The center of the "plus" shape which is the end of the line of self-intersection is a PINCH POINT. The coefficients of the FIRST FUNDAMENTAL FORM are

$$E = 1 + v^2 \quad (4)$$

$$F = uv \quad (5)$$

$$G = u^2 + 4v^2 \quad (6)$$

and the SECOND FUNDAMENTAL FORM are

$$e = 0 \quad (7)$$

$$f = \frac{2u}{\sqrt{u^2 + 4v^2 + 4v^4}} \quad (8)$$

$$g = -\frac{2u}{\sqrt{u^2 + 4v^2 + 4v^4}} \quad (9)$$

giving AREA ELEMENT

$$dA = \sqrt{u^2 + 4v^2(1 + v^2)} \quad (10)$$

and GAUSSIAN CURVATURE and MEAN CURVATURE

$$K = -\frac{4v^2}{(u^2 + 4v^2 + 4v^4)^2} \quad (11)$$

$$H = -\frac{u(1 + 3v^2)}{(u^2 + 4v^2 + 4v^4)^{3/2}} \quad (12)$$

Whitney-Graustein Theorem

A 1937 theorem which classified planar regular closed curves up to regular HOMOTOPY by their WINDING NUMBERS. In his thesis, S. Smale generalized this result to regular closed curves on an n-MANIFOLD.

Whitney-Mikhlin Extension Constants

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let $B_n(r)$ be the n-D closed BALL of RADIUS $r > 1$ centered at the ORIGIN. A function which is defined on $B(r)$ is called an extension to $B(r)$ of a function f defined on $B(1)$ if

$$F(x) = f(x) \ \forall x \in B(1) \quad (1)$$

Given 2 BANACH SPACES of functions defined on $B(1)$ and $B(r)$, find the extension operator from one to the other of minimal norm. Mikhlin (1986) found the best constants χ such that this condition, corresponding to the Sobolev $W(1, 2)$ integral norm, is satisfied,

$$\sqrt{\int_{B(1)}\left[[f(x)]^2+\sum_{j=1}^{n}\left(\frac{\partial f}{\partial x_j}\right)^2\right]dx}$$

$$\leq \chi\sqrt{\int_{B(r)}\left[[F(x)]^2+\sum_{j=1}^{n}\left(\frac{\partial F}{\partial x_j}\right)^2\right]dx}. \quad (2)$$

$\chi(1, r) = 1$. Let

$$v = \tfrac{1}{2}(n-2), \quad (3)$$

then for $n > 2$,

$$\chi(n, r) = \sqrt{1+\frac{I_v(1)}{I_{v+1}(1)}\frac{I_v(r)K_{v+1}(1)+K_v(r)I_{v+1}(1)}{I_v(r)K_v(1)-K_v(r)I_v(1)}}, \quad (4)$$

where $I_v(z)$ is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND and $K_v(z)$ is a MODIFIED BESSEL FUNCTION OF THE SECOND KIND. For $n = 2$,

$$\chi(2, r) = \max\left\{\sqrt{1+\frac{I_v(1)}{I_{v+1}(1)}\frac{I_v(r)K_{v+1}(1)+K_v(r)I_{v+1}(1)}{I_v(r)K_v(1)-K_v(r)I_v(1)}},\right.$$

$$\left.\sqrt{1+\frac{I_1(1)}{I_1(1)+I_2(1)}\left[1+\frac{I_1(r)K_0(1)+K_1(r)I_0(1)}{I_1(r)K_1(1)-K_1(r)I_1(1)}\right]}\right\}, \quad (5)$$

For $r \to \infty$,

$$\chi(n, \infty) = \sqrt{1+\frac{I_v(1)}{I_{v+1}(1)}\frac{K_v(1)}{K_v(1)}}, \quad (6)$$

which is bounded by

$$n-1 < \chi(n, \infty) < \sqrt{(n-1)^2+4} \quad (7)$$

For ODD n, the RECURRENCE RELATIONS

$$a_{k+1} = a_{k-1} - (2k-1)a_k \quad (8)$$

$$b_{k+1} = b_{k-1} - (2k-1)b_k \quad (9)$$

with

$$a_0 = e + e^{-1} \quad (10)$$

$$a_1 = e - e^{-1} \quad (11)$$

$$b_0 = e^{-1} \quad (12)$$

$$b_1 = e^{-1} \quad (13)$$

where E is the constant 2.71828..., give

$$\chi(2k+1, \infty) = \sqrt{1+\frac{a_k}{a_{k+1}}\frac{b_{k+1}}{b_k}}. \quad (14)$$

The first few are

$$\chi(3, \infty) = e \quad (15)$$

$$\chi(5, \infty) = \sqrt{\frac{e^2}{e^2-7}} \quad (16)$$

$$\chi(7, \infty) = \sqrt{\frac{2}{7}}\sqrt{\frac{e^2}{37-5e^2}} \quad (17)$$

$$\chi(9, \infty) = \frac{1}{\sqrt{37}}\sqrt{\frac{e^2}{18e^2-133}} \quad (18)$$

$$\chi(11, \infty) = \frac{1}{\sqrt{133}}\sqrt{\frac{e^2}{2431-329e^2}} \quad (19)$$

$$\chi(13, \infty) = \sqrt{\frac{2}{2431}}\sqrt{\frac{e^2}{3655e^2-27007}}. \quad (20)$$

Similar formulas can be given for even n in terms of $I_0(1)$, $I_1(1)$, $K_0(1)$, $K_1(1)$.

Whittaker Differential Equation

$$\frac{d^2u}{dz^2}+\frac{du}{dz}+\left(\frac{k}{z}+\frac{\frac{1}{4}-m^2}{z^2}\right)u = 0 \quad (1)$$

Let $u \equiv e^{-z/2}W_{k,m}(z)$, where $W_{k,m}(z)$ denotes a WHITTAKER FUNCTION. Then (1) becomes

$$\frac{d}{dz}\left(-\tfrac{1}{2}e^{-z/2}W+e^{-z/2}W'\right)+\left(-\tfrac{1}{2}e^{-z/2}W+e^{-z/2}W'\right)$$

$$+\left(\frac{k}{z}+\frac{\frac{1}{4}-m^2}{z^2}\right)e^{-z/2}W = 0. \quad (2)$$

Rearranging,

$$\left(\tfrac{1}{4}e^{-z/2}W-\tfrac{1}{2}e^{-z/2}W'-\tfrac{1}{2}e^{-z/2}W'+e^{-z/2}W''\right)p$$

$$+\left(-\tfrac{1}{2}e^{-z/2}W+e^{-z/2}W'\right)+\left(\frac{k}{z}+\frac{\frac{1}{4}-m^2}{z^2}\right)e^{-z/2}W = 0 \quad (3)$$

$$-\tfrac{1}{4}e^{-z/2}W+e^{-z/2}W''+\left(\frac{k}{z}+\frac{\frac{1}{4}-m^2}{z^2}\right)e^{-z/2}W = 0, \quad (4)$$

so

$$W''+\left(-\frac{1}{4}+\frac{k}{z}+\frac{\frac{1}{4}-m^2}{z^2}\right)W = 0, \quad (5)$$

where $W' \equiv dW/dz$ (Abramowitz and Stegun 1972, p. 505; Zwillinger 1997, p. 128). The solutions are known as WHITTAKER FUNCTIONS. Replacing $W(z)$ by $y(x)$, the solutions can also be written in the form

$$y = e^{-x/2} x^{m+1/2} [C_1 U(\tfrac{1}{2} - k + m, 2m+1, x) + C_2 L^{2m}_{-1/2+k-m}(x)], \qquad (6)$$

where $U(a, b, z)$ is a CONFLUENT HYPERGEOMETRIC FUNCTION OF THE SECOND KIND and $L_n^a(x)$ is a generalized LAGUERRE POLYNOMIAL.

Whittaker Function

Solutions to the WHITTAKER DIFFERENTIAL EQUATION. The linearly independent solutions are

$$M_{k,m}(z) \equiv z^{1/2+m} e^{-z/2} \times \left[1 + \frac{\frac{1}{2} + m - k}{1!(2m+1)} z + \frac{\left(\frac{1}{2} + m - k\right)\left(\frac{3}{2} + m - k\right)}{2!(2m+1)(2m+2)} z^2 + \ldots\right], \qquad (1)$$

and $M_{k,-m}(z)$, where $M_{k,m}(z)$ is a CONFLUENT HYPERGEOMETRIC FUNCTION. In terms of CONFLUENT HYPERGEOMETRIC FUNCTIONS, the Whittaker functions are

$$M_{k,m}(z) = e^{-z/2} z^{m+1/2} {}_1F_1\left(\tfrac{1}{2} + m - k, 1 + 2m; z\right) \qquad (2)$$

$$W_{k,m}(z) = e^{-z/2} z^{m+1/2} U\left(\tfrac{1}{2} + m - k, 1 + 2m; z\right) \qquad (3)$$

(Abramowitz and Stegun 1972, p. 505; Whittaker and Watson 1990, pp. 339–51). However, the CONFLUENT HYPERGEOMETRIC FUNCTION disappears when $2m$ is an INTEGER, so Whittaker functions are often defined instead. The Whittaker functions are related to the PARABOLIC CYLINDER FUNCTIONS. When $|\arg z| < 3\pi/2$ and $2m$ is not an INTEGER,

$$W_{k,m}(z) = \frac{\Gamma(-2m)}{\Gamma\left(\frac{1}{2} - m - k\right)} M_{k,m}(z) + \frac{\Gamma(2m)}{\Gamma\left(\frac{1}{2} + m - k\right)} M_{k,-m}(z). \qquad (4)$$

When $|\arg(-z)| < 3\pi/2$ and $2m$ is not an INTEGER,

$$W_{-k,m}(-z) = \frac{\Gamma(-2m)}{\Gamma\left(\frac{1}{2} - m - k\right)} M_{-k,m}(-z) + \frac{\Gamma(2m)}{\Gamma\left(\frac{1}{2} + m + k\right)} M_{-k,-m}(-z). \qquad (5)$$

Whittaker functions satisfy the RECURRENCE RELATIONS

$$W_{k,m}(z) = z^{1/2} W_{k-1/2, m-1/2}(z) + \left(\tfrac{1}{2} - k + m\right) W_{k-1,m}(z) \qquad (6)$$

$$W_{k,m}(z) = z^{1/2} W_{k-1/2, m+1/2}(z) + \left(\tfrac{1}{2} - k - m\right) W_{k-1,m}(z) \qquad (7)$$

$$z W'_{k,m}(z) = \left(k - \tfrac{1}{2} z\right) W_{k,m}(z) - \left[m^2 - \left(k - \tfrac{1}{2}\right)^2\right] W_{k-1,m}(z). \qquad (8)$$

Whole Number

One of the numbers 1, 2, 3, ... (Sloane's A000027), also called the COUNTING NUMBERS or NATURAL NUMBERS. 0 is sometimes included in the list of "whole" numbers (Bourbaki 1968, Halmos 1974), but there seems to be no general agreement. Some authors also interpret "whole number" to mean "a number having FRAC-

TIONAL PART of zero," making the whole numbers equivalent to the integers.

Due to lack of standard terminology, the following terms are recommended in preference to "COUNTING NUMBER," "NATURAL NUMBER," and "whole number."

set	name	symbol
..., -2, -1, 0, 1, 2, ...	INTEGERS	Z
1, 2, 3, 4, ...	POSITIVE INTEGERS	Z+
0, 1, 2, 3, 4, ...	NONNEGATIVE INTEGERS	Z*
0, -1, -2, -3, -4, ...	NONPOSITIVE INTEGERS	
-1, -2, -3, -4, ...	NEGATIVE INTEGERS	Z−

The only Wiedersehen manifolds are the standard round spheres, as was established by proof of the BLASCHKE CONJECTURE.

See also BLASCHKE CONJECTURE

Wieferich Prime

A Wieferich prime is a PRIME p which is a solution to the CONGRUENCE equation

$$2^{p-1} \equiv 1 \pmod{p^2}.$$

Note the similarity of this expression to the special case of FERMAT'S LITTLE THEOREM

$$2^{p-1} \equiv 1 \pmod{p},$$

which holds for *all* ODD PRIMES. However, the only Wieferich primes less than 4×10^{12} are $p = 1093$ and 3511 (Lehmer 1981, Crandall 1986, Crandall *et al.* 1997). Interestingly, one less than these numbers have suggestive periodic BINARY representations

$$1092 = 10001000100_2$$

$$3510 = 110110110110_2.$$

A PRIME factor p of a MERSENNE NUMBER $M_q = 2^q - 1$ is a Wieferich prime IFF $p^2 | 2^q - 1$. Therefore, MERSENNE PRIMES are *not* Wieferich primes.

If the first case of FERMAT'S LAST THEOREM is false for exponent p, then p must be a Wieferich prime (Wieferich 1909). If $p | 2^n \pm 1$ with p and n RELATIVELY PRIME, then p is a Wieferich prime IFF p^2 also divides $2^n \pm 1$. The CONJECTURE that there are no three POWERFUL NUMBERS implies that there are infinitely many Wieferich primes (Granville 1986, Vardi 1991). In addition, the ABC CONJECTURE implies that there are at least $C \ln x$ Wieferich primes $\leq x$ for some constant C (Silverman 1988, Vardi 1991).

Wielandt's Theorem

Let the $n \times n$ MATRIX A satisfy the conditions of the PERRON-FROBENIUS THEOREM and the $n \times n$ MATRIX $\mathsf{C} = c_{ij}$ satisfy

$$|c_{ij}| \leq a_{ij}$$

for $i, j = 1, 2, ..., n$. Then any EIGENVALUE λ_0 of C satisfies the inequality $|\lambda_0| \leq R$ with the equality sign holding only when there exists an $n \times n$ MATRIX $\mathsf{D} = \delta_{ij}$ (where δ_{ij} is the KRONECKER DELTA) and

$$\mathsf{C} = \frac{\lambda_0}{R} \mathsf{DAD}^{-1}.$$

Wiener Numbers

A sequence of UNCORRELATED NUMBERS α_n developed by Wiener (1926–927). The numbers are constructed by beginning with

$$\{1, -1\},$$

then forming the outer product with $\{1, -1\}$ to obtain

$$\{\{\{1, 1\}, \{1, -1\}\}, \{\{-1, 1\}, \{-1, -1\}\}\}.$$

This row is repeated twice, and its outer product is then taken to give

$$\{\{\{1, 1, 1\}, \{1, 1, -1\}, \{1, -1, 1\}, \{1, -1, -1\}\},$$
$$\{\{-1, 1, 1\}, \{-1, 1, -1\}, \{-1, -1, 1\}, \{-1, -1, -1\}\}\}.$$

This is then repeated four times. The procedure is repeated, and the result repeated eight times, and so on. The sequences from each stage are then concatenated to form the sequence 1, -1, 1, 1, 1, -1, -1, 1, -1, -1, 1, 1, 1, -1, -1, 1, -1, -1, ...

Wiener Process

A continuous-time stochastic process $W(t)$ for $t \geq 0$ with $W(0) = 0$ and such that the increment $W(t) - W(s)$ is Gaussian with mean 0 and variance $t - s$ for any $0 \leq s < t$, and increments for nonoverlapping time intervals are independent. Brownian motion (i.e., random walk with random step sizes) is the most common example of a Wiener process.

Wiener Space

MALLIAVIN CALCULUS, WIENER MEASURE

Wiener-Khintchine Theorem

Recall the definition of the AUTOCORRELATION function $C(t)$ of a function $E(t)$,

$$C(t) \equiv \int_{-\infty}^{\infty} \bar{E}(\tau) E(t + \tau)\, d\tau. \qquad (1)$$

Also recall that the FOURIER TRANSFORM of $E(t)$ is defined by

$$E(\tau) \equiv \int_{-\infty}^{\infty} E_\nu e^{-2\pi i \nu \tau} d\nu, \qquad (2)$$

giving a COMPLEX CONJUGATE of

$$\bar{E}(\tau) \equiv \int_{-\infty}^{\infty} \bar{E}_\nu e^{2\pi i \nu \tau} d\nu \qquad (3)$$

Plugging $\bar{E}(\tau)$ and $E(t + \tau)$ into the AUTOCORRELATION function therefore gives

$$C(t)=\int_{-\infty}^{\infty}\left[\int_{-\infty}^{\infty}\bar{E}_\nu e^{2\pi i\nu\tau}d\nu\right]\left[\int_{-\infty}^{\infty}\bar{E}_{\nu'}e^{-2\pi i\nu'(t+\tau)}d\nu'\right]d\tau$$
$$=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\bar{E}_\nu E_{\nu'}e^{-2\pi i\tau(\nu'-\nu)}e^{-2\pi i\nu' t}\,d\tau\,d\nu\,d\nu'$$
$$=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\bar{E}_\nu E_{\nu'}\delta(\nu'-\nu)e^{-2\pi i\nu' t}d\nu\,d\nu'$$
$$=\int_{\infty}^{\infty}\bar{E}_\nu E_\nu e^{-2\pi i\nu t}d\nu$$
$$=\int_{-\infty}^{\infty}|E_\nu|^2 e^{-2\pi i\nu t}d\nu$$
$$=\mathcal{F}\left[|E_\nu|^2\right], \quad (4)$$

so, amazingly, the AUTOCORRELATION is simply given by the FOURIER TRANSFORM of the ABSOLUTE SQUARE of $E(\nu)$,

$$C(t)=\mathcal{F}\left[|E(\nu)|^2\right]. \quad (5)$$

The Wiener-Khintchine theorem is a special case of the CROSS-CORRELATION THEOREM with $f=g$.

See also AUTOCORRELATION, CROSS-CORRELATION THEOREM, FOURIER TRANSFORM

Wiener-Lee Transform

The integral transform obtained by defining

$$\omega\equiv-\tan\left(\tfrac{1}{2}\delta\right), \quad (1)$$

and writing

$$H(\omega)=R(\omega)+iX(\omega), \quad (2)$$

where $R(\omega)$ and $X(\omega)$ are a HILBERT TRANSFORM pair as

$$H(\omega)=\rho(\delta)-i\chi(\delta) \quad (3)$$

(Papoulis 1962, p. 201).

Wiener-Lévy Process

WIENER PROCESS

Wigner 3j-Symbol

The Wigner $3j$-symbols are written

$$\begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix} \quad (1)$$

and are sometimes expressed using the related CLEBSCH-GORDAN COEFFICIENTS

$$C^j_{m_1m_2}=(j_1j_2m_1m_2|j_1j_2jm) \quad (2)$$

(Condon and Shortley 1951, pp. 74–5; Wigner 1959, p. 206), or RACAH V-COEFFICIENTS

$$V(j_1j_2j;m_1m_2m). \quad (3)$$

The allowed values of j_1, j_2, j_3, m_1, m_2, and m_3 are given by the constraints placed on CLEBSCH-GORDAN COEFFICIENTS. The Wigner $3j$-symbols are returned by the *Mathematica* function ThreeJSymbol[{*j1*, *m1*}, {*j2*, *m2*}, {*j3*, *m3*}].

Connections among the Wigner $3j$, Clebsch-Gordan, and Racah V symbols are given by

$$(j_1j_2m_1m_2|j_1j_2jm)=(-1)^{m+j_1-j_2}\sqrt{2j+1}\begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & -m \end{pmatrix} \quad (4)$$

$$(j_1j_2m_1m_2|j_1j_2jm)=(-1)^{j+m}\sqrt{2j+1}V(j_1j_2j;m_1m_2-m) \quad (5)$$

$$V(j_1j_2j;m_1m_2-m)=(-1)^{-j_1+j_2+j}\begin{pmatrix} j_1 & j_2 & j_1 \\ m_2 & m & m_2 \end{pmatrix}. \quad (6)$$

The Wigner $3j$-symbols have the symmetries

$$\begin{pmatrix} j_1 & j_2 & j_1 \\ m_1 & m_2 & m \end{pmatrix}=\begin{pmatrix} j_1 & j & j_1 \\ m_2 & m & m_1 \end{pmatrix}$$
$$=\begin{pmatrix} j & j_2 & j_2 \\ m & m_1 & m_2 \end{pmatrix}$$
$$=(-1)^{j_1+j_2+j}\begin{pmatrix} j_2 & j_1 & j \\ m_2 & m_1 & m \end{pmatrix}$$
$$=(-1)^{j_1+j_2+j}\begin{pmatrix} j_1 & j & j_2 \\ m_1 & m & m_2 \end{pmatrix}$$
$$=(-1)^{j_1+j_2+j}\begin{pmatrix} j & j_2 & j_1 \\ m & m_2 & m_1 \end{pmatrix}$$
$$=(-1)^{j_1+j_2+j}\begin{pmatrix} j & j_2 & j \\ -m_1 & -m_2 & -m \end{pmatrix}. \quad (7)$$

The symbols obey the orthogonality relations

$$\sum_{j,m}(2j+1)\begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & m \end{pmatrix}\begin{pmatrix} j_1 & j_2 & j \\ m_1' & m_2' & m \end{pmatrix}=\delta_{m_1m_1'}\delta_{m_2m_2'} \quad (8)$$

$$\sum_{m_1,m_2}(2j+1)\begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & m \end{pmatrix}\begin{pmatrix} j_1 & j_2 & j' \\ m_1 & m_2 & m' \end{pmatrix}=\delta_{jj'}\delta_{mm'}, \quad (9)$$

where δ_{ij} is the KRONECKER DELTA.

General formulas are very complicated, but some specific cases are

$$\begin{pmatrix} j_1 & j_2 & j_1+j_2 \\ m_1 & m_2 & -m_1-m_2 \end{pmatrix} = (-1)^{j_1-j_2+m_1+m_2}$$

$$\times \left[\frac{(2j_1)!(2j_2)!}{(2j_1+2j_2+1)(j_1+m_1)} \right.$$

$$\left. \times \frac{(j_1+j_2+m_1+m_2)!(j_1+j_2-m_1-m_2)!}{(j_1-m_1)(j_2+m_2)(j_2-m_2)!} \right]^{1/2} \quad (10)$$

$$\begin{pmatrix} j_1 & j_2 & j \\ j_1 & -j_1 & -m \end{pmatrix} = (-1)^{-j_1+j_2+m}$$

$$\times \left[\frac{(2j_1)!(-j_1+j_2+j)!}{(j_1+j_2+j+1)!(j_1-j_2+j)!} \right.$$

$$\left. \times \frac{(j_1+j_2+m_1+m_2)!(j_1+j_2-m_1-m_2)!}{(j_1+j_2-j)!(j_1+j_2-j)!(-j_1+j_2-m)!(j+m)!} \right] \quad (11)$$

$$\begin{pmatrix} j_1 & j_2 & j \\ 0 & 0 & 0 \end{pmatrix} = \begin{cases} (-1)^g \sqrt{\frac{(2g-2j_1)(2g-2j_2)!(2g-2j)!}{(2g+1)!}} \\ \quad \times \frac{g!}{(g-j_1)!(g-j_2)!(g-j)!} \\ \quad \text{if } J=2g \\ 0 \\ \quad \text{if } J=2g+1, \end{cases} \quad (12)$$

for $J \equiv j_1+j_2+j$.

For SPHERICAL HARMONICS $Y_l^m(\theta, \phi)$,

$$Y_{l_1}^{m_1}(\theta,\phi) Y_{l_2}^{m_2}(\theta,\phi) = \sum_{l,m} \sqrt{\frac{(2l_1+1)(2l_2+1)(2l+1)}{4\pi}} \times \begin{pmatrix} l_1 & l_2 & l \\ m_1 & m_2 & m \end{pmatrix} \bar{Y}_l^m(\theta,\phi) \begin{pmatrix} l_1 & l_2 & l \\ 0 & 0 & 0 \end{pmatrix}. \quad (13)$$

For values of l_3 obeying the TRIANGLE CONDITION $\Delta(l_1 l_2 l_3)$,

$$\int Y_{l_1}^{m_1}(\theta,\phi) Y_{l_2}^{m_2}(\theta,\phi) Y_{l_3}^{m_3}(\theta,\phi) \sin\theta \, d\theta \, d\phi = \sqrt{\frac{(2l_1+1)(2l_2+1)(2l_3+1)}{4\pi}} \begin{pmatrix} l_1 & l_2 & l_3 \\ 0 & 0 & 0 \end{pmatrix} \times \begin{pmatrix} l_1 & l_2 & l_3 \\ m_1 & m_2 & m_3 \end{pmatrix} \quad (14)$$

and

$$\frac{1}{2} \int Pl_1(\cos\theta) Pl_2(\cos\theta) \sin\theta \, d\theta = \begin{pmatrix} l_1 & l_2 & l_3 \\ 0 & 0 & 0 \end{pmatrix}^2. \quad (15)$$

Wigner 6j-Symbol

A generalization of CLEBSCH-GORDAN COEFFICIENTS and WIGNER 3*J*-SYMBOL which arises in the coupling of three angular momenta. The Wigner 6*j*-symbols are returned by the *Mathematica* function `SixJSymbol[{j1, j2, j3}, {j4, j5, j6}]`.

Let tensor operators $T^{(k)}$ and $U^{(k)}$ act, respectively, on subsystems 1 and 2 of a system, with subsystem 1 characterized by angular momentum $\mathbf{j}_1$ and subsystem 2 by the angular momentum $\mathbf{j}_2$. Then the matrix elements of the scalar product of these two tensor operators in the coupled basis $J = \mathbf{j}_1 + \mathbf{j}_2$ are given by

$$(\tau_1' j_1' \tau_2' j_2' J' M' | T^{(k)} \cdot U^{(k)} | \tau_1 j_1 \tau_2 j_2 J M) = \delta_{JJ'} \delta_{MM'} (-1)^{j_1+j_2'+J} \begin{Bmatrix} J & j_2' & j_1' \\ k & j_1 & j_2 \end{Bmatrix} \times (\tau_1' j_1' \| T^{(k)} \| \tau_1 j_1)(\tau_1' j_2' \| U^{(k)} \| \tau_2 j_2), \quad (1)$$

where

$$\begin{Bmatrix} J & j_2' & j_1' \\ k & j_1 & j_2 \end{Bmatrix}$$

is the Wigner 6*j*-symbol and τ_1 and τ_2 represent additional pertinent quantum numbers characterizing subsystems 1 and 2 (Gordy and Cook 1984).

Edmonds (1968) gives analytic forms of the 6*j*-symbol for simple cases, and Shore and Menzel (1968) and Gordy and Cook (1984) give

$$\begin{Bmatrix} a & b & c \\ 0 & c & b \end{Bmatrix} = \frac{(-1)^s}{\sqrt{(2b+1)(2c+1)}} \tag{2}$$

$$\begin{Bmatrix} a & b & c \\ 1 & c & b \end{Bmatrix} = \frac{2(-1)^{s+1}X}{\sqrt{2b(2b+1)(2b+2)2c(2c+1)(2c+2)}} \tag{3}$$

$$\begin{Bmatrix} a & b & c \\ 2 & c & b \end{Bmatrix} = \frac{2(-1)^s[3X(X-1)-4b(b+1)c(c+1)]}{\sqrt{(2b-1)2b(2b+1)(2b+2)(2b+3)(2c-1)2c(2c+1)(2c+2)(2c+3)}}, \tag{4}$$

where

$$s \equiv a+b+c \tag{5}$$

$$X \equiv b(b+1)+c(c+1)-a(a+1). \tag{6}$$

Wigner 9j-Symbol

A generalization of CLEBSCH-GORDAN COEFFICIENTS and WIGNER 3*J*- and WIGNER 6*J*-SYMBOLS which arises in the coupling of four angular momenta and can be written in terms of the WIGNER 3*J*- and WIGNER 6*J*-SYMBOLS. Let tensor operators $T^{(k_1)}$ and $U^{(k_2)}$ act, respectively, on subsystems 1 and 2. Then the reduced matrix element of the product $T^{(k_1)} \times U^{(k_2)}$ of these two irreducible operators in the coupled representation is given in terms of the reduced matrix elements of the individual operators in the uncoupled representation by

$$\left(\tau'\tau'_1 j'_1 \tau'_2 j'_2 J' \| \left[T^{(k_1)} \times U^{(k_2)}\right]^{(k)} \| \tau\tau_1 j_1 \tau_2 j_2 J\right)$$

$$= \sqrt{(2J+1)(2J'+1)(2k+1)} \sum_{\tau''} \begin{Bmatrix} j'_1 & j_1 & k_1 \\ j'_2 & j_2 & k_2 \\ J' & J & k \end{Bmatrix}$$

$$\times \left(\tau'\tau'_1 j'_1 \| T^{(k_1)} \| \tau''\tau_1 j_1\right)\left(\tau''\tau'_2 j'_2 \| U^{(k_2)} \| \tau\tau_2 j_2\right), \tag{1}$$

where

$$\begin{Bmatrix} j'_1 & j_1 & k_1 \\ j'_2 & j_2 & k_2 \\ J' & J & k \end{Bmatrix}$$

is a Wigner 9*j*-symbol (Gordy and Cook 1984).

Shore and Menzel (1968) give the explicit formulas

$$\begin{Bmatrix} a & b & C \\ d & e & F \\ G & H & J \end{Bmatrix} = \sum_x (-1)^{2x}(2x+1)$$

$$\times \begin{Bmatrix} a & b & C \\ F & J & x \end{Bmatrix} \begin{Bmatrix} d & e & F \\ b & x & H \end{Bmatrix} \begin{Bmatrix} G & H & J \\ x & a & d \end{Bmatrix} \tag{2}$$

$$\begin{Bmatrix} a & b & J \\ c & d & J \\ K & K & 0 \end{Bmatrix} = \frac{(-1)^{b+c+J+K}}{\sqrt{(2J+1)(2K+1)}} \begin{Bmatrix} a & b & J \\ d & c & K \end{Bmatrix} \tag{3}$$

$$\begin{Bmatrix} S & S & 1 \\ L & L & 2 \\ J & J & 1 \end{Bmatrix} = \frac{\begin{Bmatrix} S & L & J \\ L & S & 1 \end{Bmatrix} \begin{Bmatrix} J & L & S \\ L & J & 1 \end{Bmatrix}}{5 \begin{Bmatrix} 2 & L & L \\ L & 1 & 1 \end{Bmatrix}} + \frac{(-1)^{S+L+J+1}}{15(2L+1)} \frac{\begin{Bmatrix} S & L & J \\ L & S & 1 \end{Bmatrix}}{\begin{Bmatrix} 2 & L & L \\ L & 1 & 1 \end{Bmatrix}}. \tag{4}$$

Wigner-Eckart Theorem

A theorem of fundamental importance in spectroscopy and angular momentum theory which provides both (1) an explicit form for the dependence of all matrix elements of irreducible tensors on the projection quantum numbers and (2) a formal expression of the conservation laws of angular momentum (Rose 1995).

The theorem states that the dependence of the matrix element $(j'm'|T_{LM}|jm)$ on the projection quantum numbers is entirely contained in the WIGNER 3*J*-SYMBOL (or, equivalently, the CLEBSCH-GORDAN COEFFICIENT), given by

$$(j'm'|T_{LM}|jm) = C(jLj'; mMm')(j'\|T_L\|j),$$

where $C(jLj';mMm')$ is a CLEBSCH-GORDAN COEFFICIENT and T_{LM} is a set of tensor operators (Rose 1995, p. 85).

Wilbraham-Gibbs Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let a piecewise smooth function f with only finitely many discontinuities (which are all jumps) be defined on $[-\pi, \pi]$ with FOURIER SERIES

$$a_k = \frac{1}{\pi}\int_{-\pi}^{\pi} f(t)\cos(kt)\,dt \tag{1}$$

$$b_k = \frac{1}{\pi}\int_{-\pi}^{\pi} f(t)\sin(kt)\,dt, \tag{2}$$

$$S_n(f,x) = \tfrac{1}{2}a_0 + \left\{\sum_{k=1}^{n}[a_k\cos(kx) + b_k\sin(kx)]\right\}. \tag{3}$$

Let a discontinuity be at $x = c$, with

$$\lim_{x\to c^-} f(x) > \lim_{x\to c^+} f(x), \tag{4}$$

so

$$D \equiv \left[\lim_{x\to c^-} f(x)\right] - \left[\lim_{x\to c^+} f(x)\right] > 0. \tag{5}$$

Define

$$\phi(c) = \tfrac{1}{2}\left[\lim_{x\to c^-} f(x) + \lim_{x\to c^+} f(x)\right], \tag{6}$$

and let $x = x_n < c$ be the first local minimum and $x = \xi_n > c$ the first local maximum of $S_n(f,x)$ on either side of x_n. Then

$$\lim_{n\to\infty} S_n(f,x_n) = \phi(c) + \frac{D}{\pi}G' \tag{7}$$

$$\lim_{n\to\infty} S_n(f,\xi_n) = \phi(c) - \frac{D}{\pi}G', \tag{8}$$

where

$$G' \equiv \int_0^{\pi} \operatorname{sinc}\theta\,d\theta = 1.851937052\ldots \tag{9}$$

Here, $\operatorname{sinc} x \equiv \sin x/x$ is the SINC FUNCTION. The FOURIER SERIES of $y = x$ therefore does not converge to $-\pi$ and π at the ends, but to $-2G'$ and $2G'$. This phenomenon was observed by Wilbraham (1848) and Gibbs (1899). Although Wilbraham was the first to note the phenomenon, the constant G' is frequently (and unfairly) credited to Gibbs and known as the GIBBS CONSTANT. A related constant sometimes also called the GIBBS CONSTANT is

$$\begin{aligned} G &\equiv \frac{2}{\pi}G' = \frac{2}{\pi}\int_0^{\pi}\operatorname{sinc} x\,dx \\ &= 1.17897974447216727\ldots \end{aligned} \tag{10}$$

(Le Lionnais 1983).

Wilcoxon Rank Sum Test

A nonparametric alternative to the two-sample t-test.

See also PAIRED T-TEST, PARAMETRIC TEST

Wilcoxon Signed Rank Test

A nonparametric alternative to the PAIRED T-TEST which is similar to the FISHER SIGN TEST. This test assumes that there is information in the magnitudes of the differences between paired observations, as well as the signs. Take the paired observations, calculate the differences, and rank them from smallest to largest by ABSOLUTE VALUE. Add all the ranks associated with POSITIVE differences, giving the T_+ statistic. Finally, the P-VALUE associated with this statistic is found from an appropriate table. The Wilcoxon test is an R-ESTIMATE.

See also FISHER SIGN TEST, HYPOTHESIS TESTING, PAIRED T-TEST, PARAMETRIC TEST

Wild Knot

A KNOT which is not a TAME KNOT.

See also TAME KNOT

References

Milnor, J. "Most Knots are Wild." *Fund. Math.* **54**, 335–38, 1964.

Wild Point

For any point P on the boundary of an ordinary BALL, find a NEIGHBORHOOD of P in which the intersection with the BALL's boundary cuts the NEIGHBORHOOD into two parts, each HOMEOMORPHIC to a BALL. A wild point is a point on the boundary that has no such NEIGHBORHOOD.

See also BALL, HOMEOMORPHIC, NEIGHBORHOOD

Wilf Class

Two sets T_1 and T_2 belong to the same Wilf class if $|S_n(T_1)| = |S_n(T_2)|$ for all n, where $S_n(T)$ denotes the set of permutations on $\{1, \ldots, n\}$ that AVOID the pattern T. Two sets having the same Wilf class are said to be WILF EQUIVALENT.

See also AVOIDED PATTERN, WILF EQUIVALENT, PERMUTATION PATTERN

Wilf-Zeilberger Pair

A pair of CLOSED FORM functions (F, G) is said to be a Wilf-Zeilberger pair if

$$F(n+1,k) - F(n,k) = G(n,k+1) - G(n,k). \tag{1}$$

The Wilf-Zeilberger formalism provides succinct proofs of *known* identities and allows new identities to be discovered whenever it succeeds in finding a proof certificate for a known identity. However, if the starting point is an unknown hypergeometric sum, then the Wilf-Zeilberger method cannot discover a closed form solution, while ZEILBERGER'S ALGORITHM can.

Wilf-Zeilberger pairs are very useful in proving HYPERGEOMETRIC IDENTITIES OF THE FORM

$$\sum_k t(n,k) = \text{rhs}(n) \tag{2}$$

for which the SUMMAND $t(n,k)$ vanishes for all k outside some finite interval. Now divide by the right-hand side to obtain

$$\sum_k F(n,k) = 1, \tag{3}$$

where

$$F(n,k) \equiv \frac{t(n,k)}{\text{rhs}(n)}. \tag{4}$$

Now use a RATIONAL FUNCTION $R(n,k)$ provided by ZEILBERGER'S ALGORITHM, define

$$G(n,k) \equiv R(n,k)F(n,k). \tag{5}$$

The identity (1) then results. Summing the relation over all integers then telescopes the right side to 0, giving

$$\sum_k F(n+1,k) = \sum_k F(n,k). \tag{6}$$

Therefore, $\Sigma_k F(n,k)$ is independent of n, and so must be a constant. If F is properly normalized, then it will be true that $\Sigma_k F(0,k) = 1$.

For example, consider the BINOMIAL COEFFICIENT identity

$$\sum_{k=0}^{n} \binom{n}{k} = 2^n, \tag{7}$$

the function $R(n,k)$ returned by ZEILBERGER'S ALGORITHM is

$$R(n,k) = \frac{k}{2(k-n-1)}. \tag{8}$$

Therefore,

$$F(n,k) = \binom{n}{k} 2^{-n} \tag{9}$$

and

$$G(n,k) \equiv R(n,k)F(n,k) = \frac{k}{2(k-n-1)} \binom{n}{k} 2^{-n}$$
$$= -\frac{kn!2^{-n}}{2(n+1-k)!k!(n-k)!} = -\binom{n}{k-1} 2^{-n-1}. \tag{10}$$

Taking

$$F(n+1,k)-F(n,k)=G(n,k+1)-G(n,k) \tag{11}$$

then gives the alleged identity

$$\binom{n+1}{k}2^{-n-1}-\binom{n}{k}2^{-n} = -\binom{n}{k}2^{-n-1}+\binom{n}{k-1}2^{-n-1}? \tag{12}$$

Expanding and evaluating shows that the identity does actually hold, and it can also be verified that

$$F(0,k)=\binom{0}{k}=\begin{cases}1 & \text{for } k=0\\ 0 & \text{otherwise,}\end{cases} \tag{13}$$

so $\Sigma_k F(0,k)=1$ (Petkovsek *et al.* 1996, pp. 25–7).

For any Wilf-Zeilberger pair (F, G),

$$\sum_{n=0}^{\infty} G(n,0)=\sum_{n=1}^{\infty}[F(n,n-1)+G(n-1,n-1)] \tag{14}$$

whenever either side converges (Zeilberger 1993). In addition,

$$\sum_{n=0}^{\infty} G(n,0)=\sum_{n=0}^{\infty}\left[F(s(n+1),n)+\sum_{i=0}^{s-1}G(sn+i,n)\right] - \lim_{n\to\infty}\sum_{k=0}^{n-1}F(sn,k), \tag{15}$$

$$\sum_{k=0}^{\infty} F(0,k)=\sum_{n=0}^{\infty}G(n,0)-\lim_{k\to\infty}\sum_{n=0}^{\infty}G(n,k), \tag{16}$$

and

$$\sum_{n=0}^{\infty} G(n,0)=\sum_{n=0}^{\infty}\left[\sum_{n=0}^{t-1}F(s(n+1),tn+j) + \sum_{n=0}^{s-1}G(sn+i,tn)\right]-\lim_{n\to\infty}\sum_{k=0}^{n-1}F_{s,t}(n,k), \tag{17}$$

where

$$F_{s,t}(n,k)=\sum_{j=0}^{t-1}F(sn,tk+j) \tag{18}$$

$$G_{s,t}(n,k)=\sum_{i=0}^{s-1}G(sn+i,tk) \tag{19}$$

(Amdeberhan and Zeilberger 1997). The latter identity has been used to compute APÉRY'S CONSTANT to a large number of decimal places (Wedeniwski).

Wilkie's Theorem

Let $\phi(x_1,\ldots,x_m)$ be an $\mathscr{L}_{\exp}$ formula, where $\mathscr{L}_{\exp}\equiv \mathscr{L}\cup\{e^x\}$ and $\mathscr{L}$ is the language of ordered rings $\mathscr{L}=\{+,-,\cdot,<,0,1\}$. Then there exist $n\geq m$ and $f_1,\ldots,f_s\in \mathbb{Z}[x_1,\ldots x_n,e^{x_1},\ldots e^{x_n}]$ such that $\phi(x_1,\ldots,x_n)$ is equivalent to

$$\exists x_{m+1}\cdots\exists x_n f_1(x_1,\ldots,x_n,e^{x_1},\ldots,e^{x_n}) = \ldots = f_s(x_1,\ldots,x_n,e^{x_1},\ldots,e^{x_n})=0$$

(Marker 1996, Wilkie 1996). In other words, every formula is equivalent to an existential formula and every definable set is the projection of an exponential variety (Marker 1996).

Wilson Plug

A 3-D surface with constant VECTOR FIELD on its boundary which traps at least one trajectory which enters it.

See also VECTOR FIELD

Wilson Polynomial

The orthogonal polynomial defined by

$$p_n(x;a,b,c,d) = (a+b)_n(a+c)_n(a+d)_n \times {}_4F_3\left(\begin{matrix}-n, a+b+c+d+n-1, a-x, a+x\\ a+b, a+c, a+d\end{matrix}; 1\right).$$

The first few are

$$p_0(x;a,b,c,d) = 1$$

$$p_1(x;a,b,c,d) = abc+abd+acd+bcd+(a+b+c+d)x^2.$$

The Wilson polynomials obey the identity

$$p_n(x;a,b,c,d) = p_n(x;b,a,c,d).$$

Wilson Prime

A PRIME satisfying

$$W(p) \equiv 0 \pmod{p},$$

where $W(p)$ is the WILSON QUOTIENT, or equivalently,

$$(p-1)! \equiv -1 \pmod{p^2}.$$

5, 13, and 563 (Sloane's A007540) are the only Wilson primes less than 5×10^8 (Crandall *et al.* 1997).

Wilson's Primality Test

WILSON'S THEOREM

Wilson's Theorem

IFF p is a PRIME, then $(p-1)!+1$ is a multiple of p, that is

$$(p-1)! \equiv -1 \pmod{p}.$$

This theorem was proposed by John Wilson in 1770 (although it was previously known to Leibniz) and proved by Lagrange in 1773. Unlike FERMAT'S LITTLE THEOREM, Wilson's theorem is both NECESSARY and SUFFICIENT for primality. For a COMPOSITE NUMBER, $(n-1)! \equiv 0 \pmod{n}$ except when $n = 4$.

See also FERMAT'S LITTLE THEOREM, WILSON'S THEOREM COROLLARY, WILSON'S THEOREM (GAUSS'S GENERALIZATION)

Wilson's Theorem (Gauss's Generalization)

Let $P(n)$ be the product of INTEGERS that are less than or equal to and RELATIVELY PRIME to an integer n. Then

$$P(n) \equiv \prod_{\substack{k=2 \\ k|n}}^{n} k = \begin{cases} -1 \pmod{n} & \text{for } n = 4, p^\alpha, 2p^\alpha \\ 1 \pmod{n} & \text{otherwise.} \end{cases}$$

When $m = 2$, this reduces to $P \equiv 1 \pmod{2}$ which is equivalent to $P \equiv -1 \pmod{2}$.

See also WILSON'S THEOREM, WILSON'S THEOREM COROLLARY

Wilson's Theorem Corollary

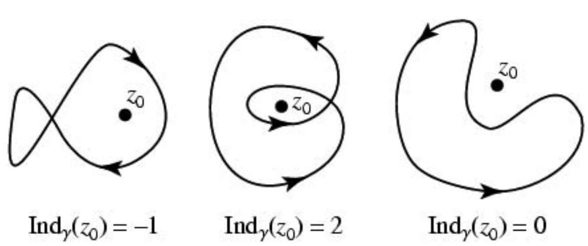
Iff a PRIME p is OF THE FORM $4x+1$, then

$$[(2x)!]^2 \equiv -1 \pmod{p}.$$

Wimp Transform

The INTEGRAL TRANSFORM defined by

$$(K\phi)(x)$$



$$= \int_{-\infty}^{\infty} G_{p+2,q}^{m,n+2}\left(t \left| \begin{matrix} 1-\nu+ix, 1-\nu-ix, (a_p) \\ (b_p) \end{matrix} \right.\right) \phi(t)\, dt,$$

where $G_{c,d}^{a,b}$ is MEIJER'S G-FUNCTION.

Winding Number (Contour)

The winding number of a CONTOUR γ about a point z_0, denoted $n(\gamma, z_0)$, is defined by

$$n(\gamma, a) = \frac{1}{2\pi i} \oint_\gamma \frac{dz}{z - z_0}$$

and gives the number of times γ curve passes around a point. The winding number is also called the index, and denoted $\text{Ind}_\gamma(z_0)$.

The contour winding number was part of the inspiration for the idea of the DEGREE of a MAP between two COMPACT, oriented MANIFOLDS of the same DIMENSION. In the language of the DEGREE of a MAP, if $\gamma : [0,1] \to \mathbb{C}$ is a closed curve (i.e., $\gamma(0) = \gamma(1)$), then it can be considered as a FUNCTION from $\mathbb{S}^1$ to $\mathbb{C}$. In that context, the winding number of γ around a point p in $\mathbb{C}$ is given by the degree of the MAP

$$\frac{\gamma - p}{|\gamma - p|}$$

from the CIRCLE to the CIRCLE.

See also RESIDUE (COMPLEX ANALYSIS)

References

Krantz, S. G. "The Index or Winding Number of a Curve about a Point." §4.4.4 in *Handbook of Complex Analysis.* Boston, MA: Birkhäuser, pp. 49–0, 1999.

Winding Number (Map)

The winding number $W(\theta)$ of a map $f(\theta)$ with initial value θ is defined by

$$W(\theta) \equiv \lim_{n \to \infty} \frac{f^n(\theta) - \theta}{n},$$

which represents the average increase in the angle θ per unit time (average frequency). A system with a RATIONAL winding number $W = p/q$ is MODE-LOCKED, whereas a system with an IRRATIONAL winding number is QUASIPERIODIC. Note that since the RATIONALS are a set of zero MEASURE on any finite interval, almost all winding numbers will be irrational, so almost all maps will be QUASIPERIODIC.

RECTANGLE FUNCTION

Winkler Conditions

Conditions arising in the study of the ROBBINS AXIOM and its connection with BOOLEAN ALGEBRA. Winkler studied Boolean conditions (such as idempotence or existence of a zero) which would make a ROBBINS ALGEBRA become a BOOLEAN ALGEBRA. Winkler showed that each of the conditions

$$\exists C, \exists D, C \vee D = C$$

$$\exists C, \exists D, !(C \vee D) = !C$$

where $A \vee B$ denotes OR and $!A$ denotes NOT, known as the first and second Winkler conditions, SUFFICES.

A computer proof demonstrated that every ROBBINS ALGEBRA satisfies the second Winkler condition, from which it follows immediately that all ROBBINS ALGEBRAS are BOOLEAN.

Winograd Transform

A discrete FAST FOURIER TRANSFORM ALGORITHM which can be implemented for $N = 2$, 3, 4, 5, 7, 8, 11, 13, and 16 points.

See also FAST FOURIER TRANSFORM

Wirtinger's Inequality

If y has period 2π, y' is L^2, and

$$\int_0^{2\pi} y\, dx = 0, \tag{1}$$

then

$$\int_0^{2\pi} y^2\, dx < \int_0^{2\pi} y'^2\, dx \tag{2}$$

unless

$$y = A\cos x + B\sin x \tag{3}$$

(Hardy *et al.* 1988).

Another inequality attributed to Wirtinger involves the KÄHLER FORM, which in $\mathbb{C}^n$ can be written

$$\omega = -\tfrac{1}{2} i \sum dz_k \wedge d\bar{z}_k. \tag{4}$$

Given $2k$ vectors $X_1, \ldots, X_{2k}$ in $\mathbb{R}^{2n} \simeq \mathbb{C}^n$, let $X = X_1 \wedge \cdots \wedge X_{2k}$ denote the oriented k-dimensional PARALLELEPIPED and $|X|$ its k-dimensional volume. Then

$$\omega^k(X) \leq k!|X|, \tag{5}$$

with equality IFF the vectors span a k-dimensional complex subspace of $\mathbb{C}^n$, and they are positively oriented. Here, ω^k is the kth EXTERIOR POWER for $1 \leq k \leq n$, and the orientation of a COMPLEX SUBSPACE is determined by its COMPLEX STRUCTURE.

Wishart Distribution

If X_i for $i = 1, \ldots, m$ has a GAUSSIAN MULTIVARIATE DISTRIBUTION with mean vector $\mu = 0$ and COVARIANCE MATRIX Σ, and X denotes the $m \times p$ matrix composed of the row vectors X_i, then the $p \times p$ matrix $\mathsf{X}^\mathrm{T}\mathsf{X}$ has a Wishart distribution with scale matrix Σ and degrees of freedom parameter m. The Wishart distribution is most typically used when describing the COVARIANCE MATRIX of multinormal samples.

See also F-DISTRIBUTION, GAUSSIAN MULTIVARIATE DISTRIBUTION, HOTELLING T-SQUARED DISTRIBUTION

Witch of Agnesi

A curve studied and named "versiera" (Italian for "she-devil" or "witch") by Maria Agnesi in 1748 in her book *Istituzioni Analitiche* (MacTutor Archive). It is also known as cubique d'Agnesi or agnésienne. Some suggest that Agnesi confused an old Italian word meaning "free to move" with another meaning "witch." The curve had been studied earlier by Fermat and Guido Grandi in 1703.

It is the curve obtained by drawing a line from the origin through the CIRCLE of radius a (OB), then picking the point with the y coordinate of the intersection with the circle and the x coordinate of the intersection of the extension of line OB with the line $y = 2a$. The curve has INFLECTION POINTS at $y = 3a/2$. The line $y = 0$ is an ASYMPTOTE to the curve.

In parametric form,

$$x = 2a\cot\theta \tag{1}$$

$$y = a[1 - \cos(2\theta)], \quad (2)$$

or

$$x = 2at \quad (3)$$

$$y = \frac{2a}{1+t^2}. \quad (4)$$

In rectangular coordinates,

$$y = \frac{8a^3}{x^2 + 4a^2}. \quad (5)$$

Witness

A witness is a number which, as a result of its number theoretic properties, guarantees either the compositeness or primality of a number n. Witnesses are most commonly used in connection with FERMAT'S LITTLE THEOREM CONVERSE. A PRATT CERTIFICATE uses witnesses to prove primality, and MILLER'S PRIMALITY TEST uses witnesses to prove compositeness.

Wolstenholme's Theorem

If p is a PRIME > 3, then the NUMERATOR of

$$1+\frac{1}{2}+\frac{1}{3}+\ldots+\frac{1}{p-1}$$

is divisible by p^2 and the NUMERATOR of

$$1+\frac{1}{2^2}+\frac{1}{3^2}+\ldots+\frac{1}{(p-1)^2}$$

is divisible by p. These imply that if $p \geq 5$ is PRIME, then

$$\binom{2p-1}{p-1} \equiv 1 \pmod{p^3}.$$

Writhe

Also called the TWIST NUMBER. The sum of crossings p of a LINK L,

$$w(L) = \sum_{p \in C(L)} \epsilon(p), \tag{1}$$

where $\epsilon(p)$ defined to be ± 1 if the overpass slants from top left to bottom right or bottom left to top right and $C(L)$ is the set of crossings of an oriented LINK. The writhe of a minimal knot diagram is *not* a KNOT INVARIANT, as exemplified by the PERKO PAIR, which have differing writhes (Hoste *et al.* 1998).

If a KNOT K is AMPHICHIRAL, then $w(K) = 0$ (Thistlethwaite). A formula for the writhe is given by

$$\mathrm{Wr}(K) = \frac{1}{4\pi} \int_K ds \int_K dt\, e^{\mu} \frac{de^{\mu}}{ds} \frac{de^{\alpha}}{dt} \tag{2}$$

where K is parameterized by $x^{\mu}(s)$ for $0 \leq s \leq L$ along the length of the knot by parameter s, and the FRAME K_f associated with K is

$$y^{\mu} = x^{\mu}(s) + \epsilon n^{\mu}(s), \tag{3}$$

where ϵ is a small parameter, $n^{\mu}(s)$ is a unit VECTOR FIELD normal to the curve at s, and the vector field e^{μ} is given by

$$e^{\mu}(s,t) = \frac{y^{\mu}(t) - x^{\mu}(s)}{|y(t) - x(s)|} \quad (4)$$

(Kaul 1999).

Letting Lk be the LINKING NUMBER of the two components of a ribbon, Tw be the TWIST, and Wr be the writhe, then the CALUGAREANU THEOREM states that

$$\mathrm{Lk}(K) = \mathrm{Tw}(K) + \mathrm{Wr}(K). \quad (5)$$

(Adams 1994, p. 187).

Wronskian

$$W(\phi_1, \ldots, \phi_n) \equiv \begin{vmatrix} \phi_1 & \phi_2 & \cdots & \phi_n \\ \phi_1' & \phi_2' & \cdots & \phi_n' \\ \vdots & \vdots & \ddots & \vdots \\ \phi_1^{(n-1)} & \phi_2^{(n-1)} & \cdots & \phi_n^{(n-1)} \end{vmatrix}.$$

If the Wronskian is NONZERO in some region, the functions ϕ_i are LINEARLY INDEPENDENT. If $W = 0$ over some range, the functions are linearly dependent somewhere in the range.

W-Transform

The W-transform of a function $f(x)$ is defined by the integral

$$(Wf)(x) = \left(W_{pq}^{mn} \left| \begin{matrix} \nu, (\alpha)_p \\ (\beta_q) \end{matrix} \right| f(t) \right)(x) \quad (1)$$

$$= \frac{1}{2\pi i} \int_{\sigma} \Gamma(\nu - ix - s, \nu + ix - s)$$

$$\times \Gamma \left[\begin{matrix} (\beta_m) + s, & 1 - (\alpha_n) - s \\ \left(\alpha_p^{n+1}\right) + s, & 1 - \left(\beta_q^{m+1}\right) - s \end{matrix} \right] f^*(1-s)\, ds, \quad (2)$$

where

$$\Gamma \left[\begin{matrix} (\beta_m) + s, & 1 - (\alpha_n) - s \\ \left(\alpha_p^{n+1}\right) + s, & 1 - \left(\beta_q^{m+1}\right) - s \end{matrix} \right]$$

$$= \Gamma \left[\begin{matrix} \beta_1 + s, & \ldots, & \beta_m + s, & 1 - \alpha_1 - s, & \ldots, & 1 - \alpha_n - s \\ \alpha_{n+1} + s, & \ldots, & \alpha_p + s & 1 - \beta_{m+1} - s, & \ldots & 1 - \beta_q - s \end{matrix} \right] \quad (3)$$

$$= \frac{\prod_{j=1}^{m} \Gamma(\beta_{j+s}) \prod_{j=1}^{n} \Gamma(1 - \alpha_j - s)}{\prod_{j=n+1}^{p} \Gamma(\alpha_{j+s}) \prod_{j=m+1}^{q} \Gamma(1 - \beta_j - s)}, \quad (4)$$

$\Re[\nu] > 1/2$, ν and the components of the vectors (α_p) and (β_q) are complex numbers satisfying the conditions $\Re[a_p]) \neq 1/2, 3/2, 5/2, \ldots,$ 3/2, 5/2, ... and $\Re[b_q] \neq -1/2, -3/2, -5/2, \ldots,$ $-3/2$, $-5/2$, ..., $f^*(s)$ is the MELLIN TRANSFORM of a function $f(x)$ and σ is the CONTOUR $\sigma = \{1/2 - i\infty, 1/2 + i\infty\}$.

Wulff Shape

An equilibrium MINIMAL SURFACE for a crystal or drop which has the least anisotropic surface free energy for a given volume. It is the anisotropic analog of a SPHERE. In the case of a sessile drop, the Wulff shapes becomes the Winterbottom shape (Dunlop and Magnen 1999, p. 31).

Wynn's Epsilon Method

A method for numerical evaluation of SUMS and PRODUCTS which samples a number of additional terms in the series and then tries to fit them to a POLYNOMIAL multiplied by a decaying exponential. Wynn's epsilon method can be applied to the terms of a series using the *Mathematica* command `SequenceLimit[l]`.

Wythoff Construction

A method of constructing UNIFORM POLYHEDRA.

See also UNIFORM POLYHEDRON

References

Har'El, Z. "Uniform Solution for Uniform Polyhedra." *Geometriae Dedicata* **47**, 57–10, 1993.

Wythoff Symbol

A symbol consisting of three rational numbers that can be used to describe UNIFORM POLYHEDRA based on how a point C in a spherical triangle can be selected so as to trace the vertices of regular polygonal faces. For example, the Wythoff symbol for the TETRAHEDRON is 3|23. There are four types of Wythoff symbols, $|p\ q\ r$, $p\ |\ q\ r$, $p\ q\ |\ r$ and $p\ q\ r\ |$, and one exceptional symbol, $\left|\ \frac{3}{2}\ \frac{5}{3}\ 3\ \frac{5}{2}\right.$ (which is used for the GREAT DIRHOMBICOSIDODECAHEDRON).

The meaning of the bars | may be summarized as follows (Wenninger 1989, p. 10; Messer). Consider a SPHERICAL TRIANGLE PQR whose angles are π/p, π/q, and π/r.

1. $|\ p\ q\ r$: C is a special point within PQR that traces snub polyhedra by even reflections .
2. $p\ |\ q\ r$ (or $p\ |\ r\ q$) : C is the vertex P.
3. $q\ r\ |\ p$ (or $r\ q\ |\ p$) : C lies on the are PQ and the bisector of the opposite angle R.
4. $pqr|$ (or any permutation of the three letters): C is the incenter of the triangle PQR.

Some special cases in terms of SCHLÄFLI SYMBOLS are

$$p\ |\ q\ 2 = p\ |\ 2\ q = \{q, p\}$$

$$2\ |\ p\ q = \begin{Bmatrix} p \\ q \end{Bmatrix}$$

$$p\ q\ |\ 2 = r\begin{Bmatrix} p \\ q \end{Bmatrix}$$

$$2\ q|\ p = t\{p, q\}$$

$$2\ p\ q\ |\ t = \begin{Bmatrix} p \\ q \end{Bmatrix}$$

$$|\ 2\ p\ q = s\begin{Bmatrix} p \\ q \end{Bmatrix}$$

Wythoff's Game

A game played with two heaps of counters in which a player may take any number from either heap or the same number from both. The player taking the last counter wins. The rth SAFE combination is $(x, x+r)$, where $x = \lfloor \phi r \rfloor$, with ϕ the GOLDEN RATIO and $\lfloor x \rfloor$ the FLOOR FUNCTION. It is also true that $x + r = \lfloor \phi^2 r \rfloor$. The first few SAFE combinations are (1, 2), (3, 5), (4, 7), (6, 10), ... (Sloane's A000201 and A001950), which are the pairs of elements from the complementary BEATTY SEQUENCES for ϕ and ϕ^2 (Wells 1986, p. 40).

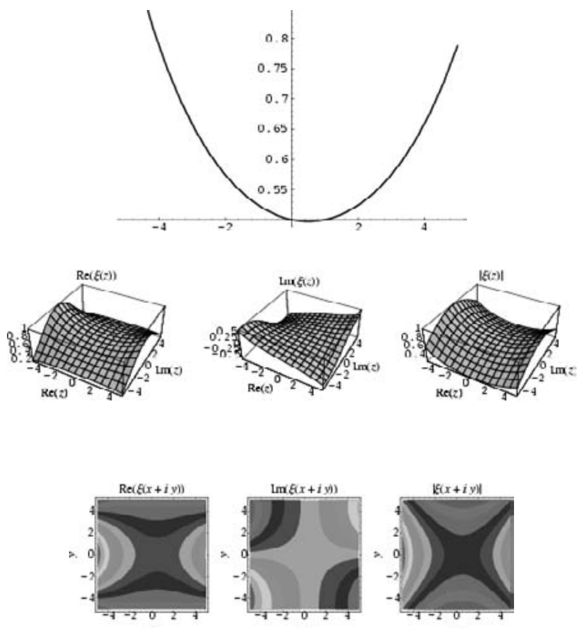
X



x-Axis

The horizontal axis of a 2-D plot in CARTESIAN COORDINATES. Physicists and astronomers sometimes call this axis the ABSCISSA, although that term is more commonly used to refer to coordinates along the X-AXIS.

See also ABSCISSA, ORDINATE, Y-AXIS, Z-AXIS

Xi Function

$$\xi(z) \equiv \tfrac{1}{2} z(z-1) \frac{\Gamma\left(\frac{1}{2}z\right)}{\pi^{z/2}} \zeta(z)$$

$$= \frac{(z-1)\Gamma\left(\frac{1}{2}z+1\right)\zeta(z)}{\sqrt{\pi^z}}, \quad (1)$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION and $\Gamma(z)$ is the GAMMA FUNCTION (Gradshteyn and Ryzhik 2000, p. 1076; Hardy 1999, p. 41). The ξ function satisfies the identity

$$\xi(1-z) = \xi(z). \quad (2)$$

The zeros of $\xi(z)$ and of its DERIVATIVES are all located on the CRITICAL STRIP $z = \sigma + it$, where $0 < \sigma < 1$. Therefore, the nontrivial zeros of the RIEMANN ZETA FUNCTION exactly correspond to those of $\xi(z)$. The function $\xi(z)$ is related to what Gradshteyn and Ryzhik (2000, p. 1074) call $\Xi(t)$ by

$$\Xi(t) \equiv \xi(z), \quad (3)$$

where $z \equiv \frac{1}{2} + it$. This function can also be defined as

$$\Xi(it) \equiv \tfrac{1}{2}\left(t^2 - \tfrac{1}{4}\right)\pi^{-t/2-1/4}\Gamma\left(\tfrac{1}{2}t + \tfrac{1}{4}\right)\zeta\left(t + \tfrac{1}{2}\right), \quad (4)$$

giving

$$\Xi(t) = -\tfrac{1}{2}\left(t^2 + \tfrac{1}{4}\right)\pi^{it/2-1/4}\Gamma\left(\tfrac{1}{4} - \tfrac{1}{2}it\right)\zeta\left(\tfrac{1}{2} - it\right). \quad (5)$$

The DE BRUIJN-NEWMAN CONSTANT is defined in terms of the $\Xi(t)$ function.

Simpson, R. E. "The Exclusive NOR (XNOR) Gate." §12.5.7 in *Introductory Electronics for Scientists and Engineers, 2nd ed.* Boston, MA: Allyn and Bacon, pp. 539 and 554, 1987.

XOR

Portions of this entry contributed by ROGER GERMUNDSSON

XOR gate

A CONNECTIVE in LOGIC known as the "exclusive or," or EXCLUSIVE DISJUNCTION. It yields true if exactly one (but not both) of two conditions is true. The XOR operation does not have a standard symbol, but is sometimes denoted $A \veebar B$ (this work) or $A \oplus B$ (Simpson 1987, pp. 539 and 550–54). $A \veebar B$ is read "A AUT B," where "aut" is Latin for "or, but not both." The circuit diagram symbol for an XOR gate is illustrated above. In SET THEORY, $A \veebar B$ is typically called the SYMMETRIC DIFFERENCE. The XOR function is implemented in *Mathematica* 4.1 as XOR.

The binary XOR operation $A \veebar B$ is identical to NONEQUIVALENCE $A \not\equiv B$. $A \veebar B$ can be implemented using AND and OR gates as

$$A \veebar B = (A \wedge !B) \vee (!A \wedge B) \quad (1)$$

$$= (A \vee) \wedge !(A \wedge B), \quad (2)$$

where $\wedge$ denotes AND and $\vee$ denotes OR, and can be implemented using only NOT and NAND gates as

$$A \veebar B = (A \barwedge !B) \barwedge (!A \barwedge B) \quad (3)$$

(Simpson 1987), where $\barwedge$ denotes NAND.

The BINARY XOR operator has the following TRUTH TABLE.

A	B	$A \veebar B$
T	T	F
T	F	T
F	T	T
F	F	F

The BINOMIAL COEFFICIENT $\binom{m}{n}$ mod 2 can be computed using the XOR operation n XOR m, making PASCAL'S TRIANGLE mod 2 very easy to construct.

For multiple arguments, XOR is defined to be true if an odd number of its arguments are true, and false otherwise. This definition is quite common in computer science, where XOR is usually thought of as addition modulo 2. In this context, it arises in polynomial algebra modulo 2, arithmetic circuits with a full adder, and in parity generating or checking. While this means that the multiargument "XOR" can no longer be thought of as "the exclusive OR" operation, this form is rarely used in mathematical logic and so does not cause very much confusion. The XOR operation is associative, so $a \veebar (b \veebar c)$ is the same as $(a \veebar b) \veebar c$. Computation of the multiargument XOR requires evaluation of all its arguments to determine the truth value, and hence there is no "lazy" special evaluation form (as there is for AND and OR).

The ternary XOR operator therefore has the following truth table.

A	B	C	$A \veebar B \veebar C$
T	T	T	T
T	T	F	F
T	F	T	F
T	F	F	T
F	T	T	F
F	T	F	T
F	F	T	T
F	F	F	F

Yahtzee

Yahtzee is a game played with five 6-sided DICE. Players take turns rolling the dice, and trying to get certain types of rolls, each with an assigned point value, as summarized in the following table. Players are allowed a total of three rolls, with any subset of dice capable of being set aside at each roll. In addition to runs of a single number, other rolls include 3 of a kind (three of the same number), 4 of a kind (four of the same number), full house (two of one number and three of another), small straight (4 numbers in a row), large straight (5 numbers in a row), Yahtzee (five of the same number), and chance (any roll).

aces	sum of 1s
twos	sum of 2s
threes	sum of 3s
fours	sum of 4s
fives	sum of 5s
sixes	sum of 6s
3 of a kind	sum of all dice
4 of a kind	sum of all dice
full house	25
sm. straight	30
lg. straight	40
Yahtzee	50
chance	sum of all dice

In a variant of the game known as triple Yahtzee, players try to get each type of roll three times over the course of the game instead of just once, with point values for each roll being placed in a single, double, or triple column, whose values are multiplied by the stated weight when scores are totaled. The following tables summarizes the probability of obtaining various rolls. In this table, lower-value rolls are excluded from the results, so, for example, the probability of obtaining a three of a kind excludes rolls that are actually fours of a kind or Yahtzees. Similarly, the three of a kind probability excludes rolls that are full houses, and the two of a kind probability excludes rolls that are small straights.

type	1	2	3	overall
2 of a kind	$\frac{65}{108}$	$\frac{65}{108}$	$\frac{65}{108}$	$\frac{1180205}{1259712}$

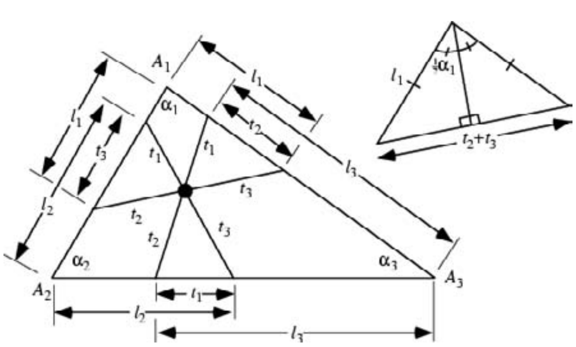
Zwillinger, D. *Handbook of Differential Equations, 3rd ed.* Boston, MA: Academic Press, p. 139, 1997.

y-Axis

The vertical axis of a 2-D plot in CARTESIAN COORDINATES. Physicists and astronomers sometimes call this axis the ORDINATE, although that term is more commonly used to refer to coordinates along the Y-AXIS.



See also ABSCISSA, ORDINATE, X-AXIS, Z-AXIS

Yff Center of Congruence

Let three ISOSCELIZERS be constructed on a TRIANGLE, one for each side. Now parallel-displace these ISOSCELIZERS until they concur in a single point. This point is called the Yff center of congruence and has TRIANGLE CENTER FUNCTION

$$\alpha = \sec\left(\tfrac{1}{2}A\right).$$

By analogy with the determination of the YFF CENTRAL TRIANGLE, the angle α_1 is related to the isoscelizer distance l_1 and the inner triangle side lengths t_i are given by

$$\sin\left(\tfrac{1}{2}\alpha_1\right) = \sqrt{\frac{1-\cos\alpha_1}{2}} = \frac{\frac{1}{2}(t_2+t_3)}{l_1}$$

and so on. Therefore, the length l_i and t_i can be determined by solving the six simultaneous equations

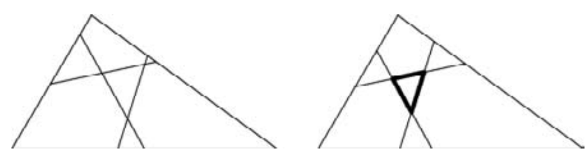
$$l_2 + l_3 - t_1 = s_1$$

$$l_1 + l_3 - t_2 = s_2$$

$$l_1 + l_2 - t_3 = s_3$$

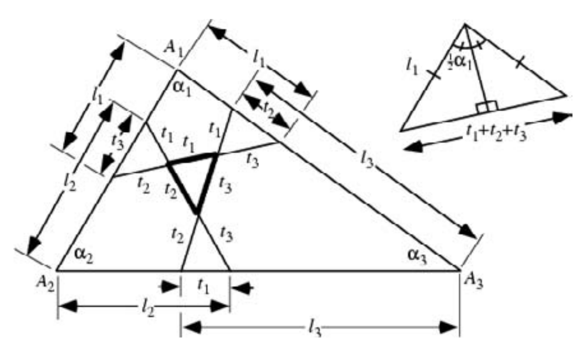
$$\left(\frac{t_2+t_3}{l_1}\right)^2 = 2\left(1 - \frac{s_2^2+s_3^2-s_1^2}{2s_2s_3}\right)$$

$$\left(\frac{t_1+t_3}{l_2}\right)^2 = 2\left(1 - \frac{s_1^2+s_3^2-s_2^2}{2s_1s_3}\right)$$



$$\left(\frac{t_1+t_2}{l_3}\right)^2 = 2\left(1 - \frac{s_1^2+s_2^2-s_3^2}{2s_1s_2}\right).$$

See also CONGRUENT ISOSCELIZERS POINT, ISOSCELIZER, YFF CENTRAL TRIANGLE



References

Kimberling, C. "Yff Center of Congruence." http://cedar.evansville.edu/~ck6/tcenters/recent/yffcc.html.

Yff Central Triangle

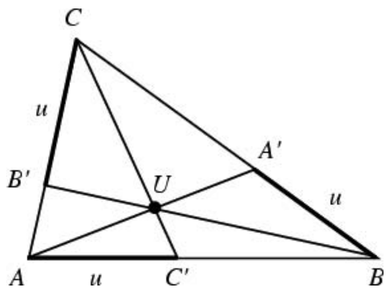
Let three ISOSCELIZERS be constructed on a TRIANGLE, one for each side. This makes all of the inner triangles SIMILAR to each other. However, there is a unique set of three isoscelizers for which the four interior triangles are congruent. The innermost triangle is called the Yff central triangle.

Let the side lengths be denoted s_i, the side lengths of the Yff central triangle t_i, and the distances of the

ISOSCELIZERS from the vertices l_i (for $i = 1, 2, 3$), then the LAW OF COSINES gives

$$\cos \alpha_1 = \frac{s_2^2 + s_3^2 - s_1^2}{2 s_2 s_3}$$

and so on, and trigonometry gives



$$\sin\left(\tfrac{1}{2}\alpha_1\right) = \sqrt{\frac{1-\cos\alpha_1}{2}} = \frac{\frac{1}{2}(t_1+t_2+t_3)}{l_1}$$

and so on. Three more equations are obtained by noting that the sums of lengths along each side must sum to that side length. Therefore, the size of the Yff central triangle and the positions of the ISOSCELIZERS can be determined by solving the six simultaneous equations

$$l_2 + l_3 - t_1 = s_1$$
$$l_1 + l_3 - t_2 = s_2$$
$$l_1 + l_2 - t_3 = s_3$$
$$\left(\frac{t_1+t_2+t_3}{l_1}\right)^2 = 2\left(1 - \frac{s_2^2+s_3^2-s_1^2}{2s_2s_3}\right)$$
$$\left(\frac{t_1+t_2+t_3}{l_2}\right)^2 = 2\left(1 - \frac{s_1^2+s_3^2-s_2^2}{2s_1s_3}\right)$$
$$\left(\frac{t_1+t_2+t_3}{l_3}\right)^2 = 2\left(1 - \frac{s_1^2+s_2^2-s_3^2}{2s_1s_2}\right).$$

See also ISOSCELIZER, YFF CENTER OF CONGRUENCE

Yff Points

Let points A', B', and C' be marked off some fixed distance x along each of the sides BC, CA, and AB. Then the lines AA', BB', and CC' concur in a point U known as the first Yff point if

$$x^3 = (a-x)(b-x)(c-x). \tag{1}$$

This equation has a single real root u, which can by obtained by solving the CUBIC EQUATION

$$f(x) = 2x^3 - px^2 + qx - r = 0, \tag{2}$$

where

$$p = a + b + c \tag{3}$$
$$q = ab + ac + bc \tag{4}$$
$$r = abc. \tag{5}$$

The ISOTOMIC CONJUGATE POINT U' is called the second Yff point. The TRIANGLE CENTER FUNCTIONS of the first and second points are given by

$$\alpha = \frac{1}{a}\left(\frac{c-u}{b-u}\right)^{1/3} \tag{6}$$

and

$$\alpha' = \frac{1}{a}\left(\frac{b-u}{c-u}\right)^{1/3}, \tag{7}$$

respectively. Analogous to the inequality $\omega \leq \pi/6$ for the BROCARD ANGLE ω, $u \leq p/6$ holds for the Yff points, with equality in the case of an EQUILATERAL TRIANGLE. Analogous to

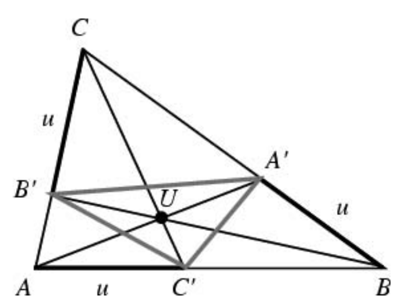
$$\omega < \alpha_i < \pi - 3\omega \tag{8}$$

for $i = 1, 2, 3$, the Yff points satisfy

$$u < a_i < p - 3u. \tag{9}$$

Yff (1963) gives a number of other interesting properties. The line UU' is PERPENDICULAR to the line containing the INCENTER I and CIRCUMCENTER O, and its length is given by

$$\overline{UU'} = \frac{4u\overline{IO}\Delta}{u^3 + abc}, \tag{10}$$



where Δ is the AREA of the TRIANGLE.

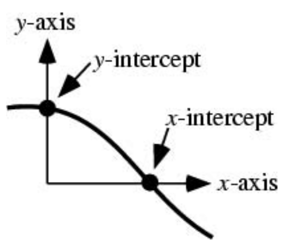
Yff Triangles

The TRIANGLE $\Delta A'B'C'$ formed by connecting the points used to construct the YFF POINTS is called the

first Yff triangle. The AREA of the triangle is

$$\Delta = \frac{u^3}{2R},$$



where R is the CIRCUMRADIUS of the original TRIANGLE ΔABC. The second Yff triangle is formed by connecting the ISOTOMIC CONJUGATE POINTS of A', B', and C'.

y-Intercept

The point at which a curve or function crosses the Y-AXIS (i.e., when $x = 0$ in 2-D).

See also LINE, X-INTERCEPT

Yin-Yang

A figure used in many Asian cultures to symbolize the unity of the two "opposite" male and female elements, the "yin" and "yang." The solid and hollow parts composing the symbol are similar and combine to make a CIRCLE. Each part consists of two equal oppositely oriented SEMICIRCLES of radius 1/2 joined at their edges, plus a SEMICIRCLE of radius 1 joining the other edges.

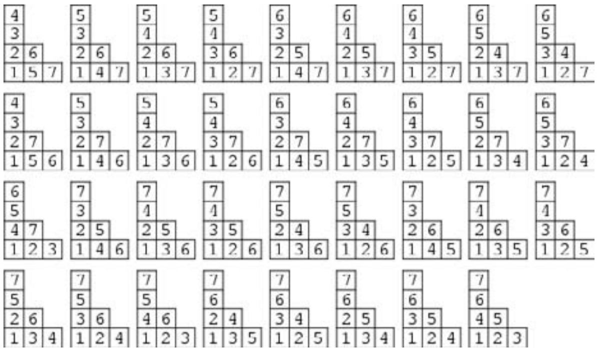
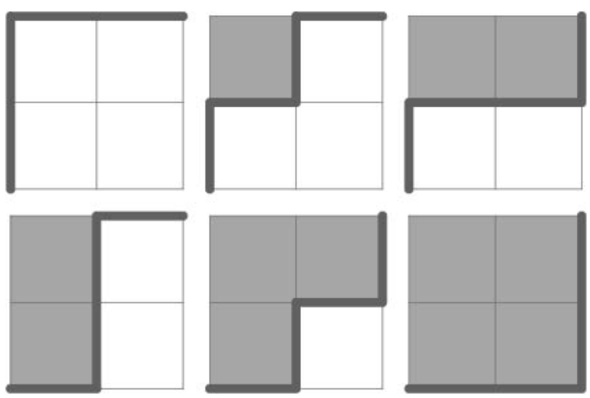
Young Tableau



The Young tableau (plural, "tableaux") of a FERRERS DIAGRAM is obtained by placing the numbers 1, ..., n in the n boxes of the diagram. A "standard" Young tableau is a Young tableau in which the numbers form a nondecreasing sequence along each line and along each column. For example, the standard Young tableaux of size $n = 3$ are given by $\{\{1, 2, 3\}\}$, $\{\{1, 3\}, \{2\}\}$, $\{\{1, 2\}, \{3\}\}$, and $\{\{1\}, \{2\}, \{3\}\}$, illustrated above. The BUMPING ALGORITHM is used to construct a standard Young tableau from a permutation of $\{1, \ldots, n\}$, and the number of standard Young tableaux of size 1, 2, 3, ... are 1, 2, 4, 10, 26, 76, 232, 764, 2620, 9496, ... (Sloane's A000085). These numbers can be generated by the RECURRENCE RELATION



$$a(n) = a(n-1) + (n-1)a(n-2)$$

with $a(1) = 1$ and $a(2) = 2$. This is the same as the number of INVOLUTIONS on n elements (Skiena 1990,

p. 32).

The number of all possible standard Young tableaux of a given shape can also be considered, and can be calculated with the HOOK LENGTH FORMULA. For example, the illustration above shows the 35 standard tableaux of shape $\{3,\ 2,\ 1,\ 1\}$.

The partitions of integers less than or equal to mn in which there are at most n parts and in which no part is larger than m correspond (1) to Young tableaux which fit inside and $m \times n$ rectangle and (2) to lattice paths which travel from the upper right corner of the rectangle to the lower left in $m+n$ leftward and downward steps. The number of Young diagrams fitting inside an $m \times n$ rectangle is given by the BINOMIAL COEFFICIENT $\binom{m+n}{m} = \binom{m+n}{n}$. The above example shows the

$$\binom{2+2}{2} = \binom{4}{2} = \frac{4!}{2!2!} = \frac{24}{4} = 6$$

Young 2×2 diagrams.

There is a correspondence between a PERMUTATION and a pair of Young tableaux, known as the SCHENSTED CORRESPONDENCE.

Young's Inequality

Let f be a real-valued, continuous, and strictly increasing function on $[0,\ c]$ with $c>0$. If $f(0)=0$, $a \in [0,\ c]$, and $b \in [0,\ f(c)]$, then

$$\int_0^a f(x)\,dx + \int_0^b f^{-1}(x)\,dx \geq ab, \tag{1}$$

where f^{-1} is the INVERSE FUNCTION of f. Equality holds IFF $b = f(a)$.

Taking the particular function $f(x) = x^{p-1}$ gives the special case

$$\frac{a^p}{p} + \left(\frac{p-1}{p}\right) b^{p/(p-1)} \geq ab, \tag{2}$$

which is often written in the symmetric form

$$\frac{a^p}{p} + \frac{b^q}{q} \geq ab, \tag{3}$$

where $a,\ b \geq 0$, $p > 1$, and

$$\frac{1}{p}+\frac{1}{q}=1. \tag{4}$$

Young's Integral

Let $f(x)$ be a REAL continuous monotonic strictly increasing function on the interval $[0, a]$ with $f(0)=0$ and $b \leq f(a)$, then

$$ab \leq \int_0^a f(x)\,dx + \int_0^b f^{-1}(y)\,dy,$$

where $f^{-1}(y)$ is the INVERSE FUNCTION. Equality holds IFF $b=f(a)$.

Zag Number

An EVEN ALTERNATING PERMUTATION number, more commonly called a TANGENT NUMBER.

See also ALTERNATING PERMUTATION, TANGENT NUMBER, ZIG NUMBER

Zak Transform

This entry contributed by RONALD M. AARTS

The Zak transform is a signal transform relevant to time-continuous signals sampled at a uniform rate and an arbitrary clock phase (Janssen 1988). The Zak transform of a signal can be considered as a mixed time-frequency representation of f

$$(Zf)_T(t,\ \nu)=T^{1/2}\sum_{k=-\infty}^{\infty} f(t+kT)e^{-2\pi ik\nu T}$$

for $0 \leq t \leq T$ and $0 \leq \nu \leq T^{-1}$. The Zak transform is sometimes also known as the Weil-Brezin map.

Zalcman's Lemma

Let f be a family of MEROMORPHIC FUNCTIONS on the UNIT DISK $\mathbb{D}$ which are not normal at 0. Then there exist sequences f_n in F, z_n, ρ_n, and a nonconstant function f meromorphic in the plane such that

$$f_n(z_n+\rho_n z) \to f(z),$$

locally and uniformly (in the spherical sense) in the COMPLEX PLANE $\mathbb{C}$ (Schwick 2000), where $z_n \to 0$ and $\rho_n \to 0$.

Zarankiewicz's Conjecture

The CROSSING NUMBER for a COMPLETE BIGRAPH is

$$\left\lfloor\frac{n}{2}\right\rfloor\left\lfloor\frac{n-1}{2}\right\rfloor\left\lfloor\frac{m}{2}\right\rfloor\left\lfloor\frac{m-1}{2}\right\rfloor,$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION. The original proof by Zarankiewicz (1954) contained an error, but was subsequently solved in some special cases by Guy (1969). The conjecture has been shown to be true for all $m, n \leq 7$, and Zarankiewicz has shown that in general, the FORMULA provides an upper bound to the actual number.

Zariski Topology

A TOPOLOGY of an infinite set whose OPEN SETS have finite complements. The Zariski topology is a TOPOLOGY which is well-suited for the study of polynomial equations in ALGEBRAIC GEOMETRY, since in Zariski topology, there are many fewer OPEN SETS than in the usual METRIC TOPOLOGY. In fact, the only CLOSED SETS are the ALGEBRAIC SETS, which are the zeros of polynomials.

For example, in $\mathbb{C}$, the only nontrivial closed sets are finite collections of points. In $\mathbb{C}^2$, there are also the zeros of polynomials such as lines $ax + by$ and cusps $x^2 + y^3$.

The Zariski topology is not HAUSDORFF. In fact, any two open sets must intersect, and cannot be DISJOINT. Also, the open sets are DENSE, in the Zariski topology as well as in the usual METRIC TOPOLOGY.

Because there are fewer open sets than in the usual topology, it is more difficult for a function to be continuous in Zariski topology. For example, a CONTINUOUS FUNCTION ($\mathbb{C}^n$, Zariski) $\to$ ($\mathbb{C}$, metric) must be a constant function. Conversely, when the range has the Zariski topology, it is easier for a function to be CONTINUOUS. In particular, the polynomials are CONTINUOUS FUNCTIONS ($\mathbb{C}^n$, Zariski) $\to$ ($\mathbb{C}$, Zariski).

Zeilberger-Bressoud Theorem

Dyson (1962abc) conjectured that the constant term in the LAURENT SERIES

$$\prod_{1\leq i\neq j\leq n}\left(1-\frac{x_i}{x_j}\right)^{a_i} \tag{1}$$

is

$$\frac{(a_1+a_2+\ldots+a_n)!}{a_1!a_2!\ldots a_n!}, \tag{2}$$

based on a problem in particle physics. The theorem is called DYSON'S CONJECTURE, and was proved by Wilson (1962) and independently by Gunson (1962). A definitive proof was subsequently published by Good (1970).

A q-analog of this theorem (Andrews 1975) states that the coefficient of $x_1^0\, x_2^0\, \ldots x_n^0$ in

$$\prod_{1\leq i\neq j\leq n}\left(\frac{x_i}{x_j}\,\epsilon_{ij};\, q\right)_{a_i} \tag{3}$$

where

$$\epsilon_{ij}\equiv\begin{cases}1 & \text{for } i<j\\ q & \text{for } i>j\end{cases} \tag{4}$$

is given by

$$\frac{(q;\, q)_{a_1+a_2+\ldots+a_n}}{(q;\, q)_{a_1}(q;\, q)_{a_2}\cdots(q;\, q)_{a_n}}. \tag{5}$$

This can also be stated in the form that the constant term of

$$\prod_{1\leq i<j\leq n}(1-x_i/x_j)(1-qx_i/q_j)\cdots(1-q^{a_i-1}x_i/x_j)$$
$$\times(1-qx_j/x_i)(1-q^2x_j/x_i)\cdots(1-q^{a_j}x_j/x_i), \tag{6}$$

is the Q-MULTINOMIAL COEFFICIENT

$$\frac{[a_1+\cdots+a_n]!}{[a_1]!\cdots[a_n]!}, \tag{7}$$

where

$$[n]!\equiv(1)(1+q)\cdots(1+q+\cdots+q^{n-1}). \tag{8}$$

The amazing proof of this theorem was given by Zeilberger and Bressoud (1985).

The full theorem reduces to Dyson's version when $q=1$. It also gives the Q-ANALOG of DIXON'S THEOREM as

$$\sum_{k=-\infty}^{\infty}(-1)^k q^{k(3k+1)/2}\binom{b+c}{c+k}\binom{c+a}{a+k}\binom{a+b}{b+k}$$
$$=\frac{(q;\, q)_{a+b+c}}{(q;\, q)_a(q;\, q)_b(q;\, q)_c} \tag{9}$$

(Andrews 1975, 1986). With $q=1$ and $a=b=c=p$, it gives the beautiful and well-known identity

$$\sum_{k=0}^{2p}(-1)^k\binom{2p}{k}^3=\frac{(-1)^p(3p)!}{(p!)^3} \tag{10}$$

(Andrews 1986).

Zeilberger's Algorithm

An ALGORITHM which finds a POLYNOMIAL recurrence for terminating HYPERGEOMETRIC IDENTITIES OF THE FORM

$$\sum_k\binom{n}{k}\frac{\prod_{i=1}^{A}(a_in+a_i'k+a_i'')!}{\prod_{i=1}^{B}(b_in+b_i'k+b_i'')!}z_k$$
$$=C\,\frac{\prod_{i=1}^{\bar A}(\bar a_in+\bar a_i')!}{\prod_{i=1}^{\bar B}(\bar b_in+\bar b_i')}\,\bar x^n,$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT, a_i, a_i', $\bar a_i$, b_i, b_i',

$\bar{b}_i$ are constant integers and a_i'', $\bar{a}'_i$, b_i'', $\bar{b}'_i$, C, x, and z are complex numbers (Zeilberger 1990). The method was called CREATIVE TELESCOPING by van der Poorten (1979), and led to the development of the amazing machinery of WILF-ZEILBERGER PAIRS.

The also exists a q-analog of the algorithm, called the q-ZEILBERGER ALGORITHM.

Zeisel Number

A number $N = p_1 p_2 \cdots p_n$ where the p_is are distinct PRIMES and $n \geq 3$ such that

$$p_i = Ap_{i-1} + B$$

for $i = 1, 2, ..., n$, p_0 taken as 1, and with A and B some fixed integers. For example, $1885 = 1 \cdot 5 \cdot 13 \cdot 29$ is a Zeisel number with $(A, B) = (2, 3)$ since

$$5 = 2 \cdot 1 + 3;\ 13 = 2 \cdot 5 + 3;\ 29 = 2 \cdot 13 + 3,$$

as is $114985 = 1 \cdot 5 \cdot 13 \cdot 29 \cdot 61$ since

$$5 = 2 \cdot 1 + 3;\ 13 = 2 \cdot 5 + 3;\ 29 = 2 \cdot 13 + 3;$$
$$61 = 2 \cdot 29 + 3.$$

The first few Zeisel numbers are 105, 1419, 1729, 1885, 4505, ... (Sloane's A051015), which correspond to constants (1, 2), (4, -1), (1, 6), (2, 3), (3, 2), ...

Zenithal Projection

AZIMUTHAL PROJECTION

Zeno's Paradoxes

A set of four PARADOXES dealing with counterintuitive aspects of continuous space and time.

1. Dichotomy paradox: Before an object can travel a given distance d, it must travel a distance $d/2$. In order to travel $d/2$, it must travel $d/4$, etc. Since this sequence goes on forever, it therefore appears that the distance d cannot be traveled. The resolution of the paradox awaited CALCULUS and the proof that infinite GEOMETRIC SERIES such as $\Sigma_{i=1}^{\infty}(1/2)^i = 1$ can converge, so that the infinite number of "half-steps" needed is balanced by the increasingly short amount of time needed to traverse the distances.
2. Achilles and the tortoise paradox: A fleet-of-foot Achilles is unable to catch a plodding tortoise which has been given a head start, since during the time it takes Achilles to catch up to a given position, the tortoise has moved forward some distance. But this is obviously fallacious since Achilles will clearly pass the tortoise! The resolution is similar to that of the dichotomy paradox.
3. Arrow paradox: An arrow in flight has an instantaneous position at a given instant of time. At that instant, however, it is indistinguishable

from a motionless arrow in the same position, so how is the motion of the arrow perceived?
4. Stade paradox: A paradox arising from the assumption that space and time can be divided only by a definite amount.

Zermelo Set Theory

The version of set theory obtained if Axiom 6 of ZERMELO-FRAENKEL SET THEORY is replaced by

6'. Selection axiom (or "axiom of subsets"): for any set-theoretic formula $A(u)$, $\forall x \exists y \forall u (u \in y \equiv u \in x \wedge A(u))$,

which can be deduced from Axiom 6. However, there seems to be some disagreement in the literature about just which axioms of ZERMELO-FRAENKEL SET THEORY constitute "Zermelo Set Theory." Mendelson (1997) does *not* include the AXIOMS OF CHOICE, FOUNDATION, REPLACEMENT In Zermelo set theory, but does includes 6'. However, Enderton (1977) includes the AXIOMS OF CHOICE and FOUNDATION, but does not include the AXIOMS OF REPLACEMENT or Selection.

Zermelo-Fraenkel Axioms

The Zermelo-Fraenkel axioms are the basis for ZERMELO-FRAENKEL SET THEORY. In the following (Iyanaga and Kawada 1980), $\exists$ stands for EXISTS, $\nexists$ for does not exist, $\in$ for "is an element of," $\varnothing$ for the EMPTY SET, $\forall$ for FOR ALL, $\Rightarrow$ for IMPLIES, ! for NOT (NEGATION), $\wedge$ for AND, $\vee$ for OR, $\equiv$ for "is EQUIVALENT to," and S denotes the union y of all the sets that are the elements of x.

1. AXIOM OF EXTENSIONALITY: $\forall x (x \in a \equiv x \in b) \Rightarrow a = b$.
2. AXIOM OF THE UNORDERED PAIR: $\exists x \forall y (y \in x \equiv y = a \vee y = b)$.
3. AXIOM OF THE SUM SET: $\exists x \forall y (y \in x \equiv \exists z \in a (y \in z))$.
4. AXIOM OF THE POWER SET: $\forall x \exists y y \in x \equiv \forall z \in y (z \in a))$.
5. AXIOM OF THE EMPTY SET: $\exists x \forall y (!y \in x)$.
6. AXIOM OF INFINITY: $\exists x (\varnothing \in x \vee \forall y \in x (y' \in x))$.
7. AXIOM OF SEPARATION: $\exists x \forall y (y \in x \equiv y \in a \wedge A(y))$.
8. AXIOM OF REPLACEMENT (or axiom of comprehension, or axiom of subsets): $\exists x \forall y \in a (\exists z A(y, z) \Rightarrow \exists z \in x A(y, z))$.
9. Axiom of regularity (or AXIOM OF FOUNDATION): $\exists x A(x) \Rightarrow \exists x (A(x) \wedge \forall y \in x (!A(y)))$.
10. AXIOM OF CHOICE: $\forall x \in a \exists A(x, y) \Rightarrow \exists y \forall x \in a A(x, y(x))$.

The system of axioms 1–9 is called ZERMELO-FRAENKEL SET THEORY, denoted "ZF." The system of axioms 1–9 minus the AXIOM OF REPLACEMENT (i.e., axioms 1–7 plus 8) is called ZERMELO SET THEORY, denoted "Z." The set of axioms 1–9 plus the AXIOM OF CHOICE is usually denoted "ZFC."

However, note that there seems to be some disagreement in the literature about just what axioms constitute "ZERMELO SET THEORY." Mendelson (1997) does *not* include the AXIOMS OF CHOICE, FOUNDATION, or REPLACEMENT in Zermelo set theory, but does include the AXIOM OF REPLACEMENT. However, Enderton (1977) includes the AXIOMS OF CHOICE and FOUNDATION, but does not include the AXIOM OF REPLACEMENT.

Abian (1969) proved CONSISTENCY and independence of four of the Zermelo-Fraenkel axioms.

Zermelo-Fraenkel Set Theory

A version of SET THEORY which is a formal system expressed in first-order predicate LOGIC. Zermelo-Fraenkel set theory is based on the ZERMELO-FRAENKEL AXIOMS.

ZERMELO-FRAENKEL SET THEORY is not finitely axiomatized. For example, the AXIOM OF REPLACEMENT is not really a single axiom, but an infinite family of axioms, since it is preceded by the stipulation that it is true "For any set-theoretic formula $A(u, v)$." Montague (1961) proved that ZERMELO-FRAENKEL SET THEORY is not finitely axiomatizable, i.e., there is no finite set of axioms which is logically equivalent to the infinite set of ZERMELO-FRAENKEL AXIOMS. VON NEUMANN-BERNAYS-GÖDEL SET THEORY provides an equivalent finitely axiomized system.

See also LOGIC, SET THEORY, VON NEUMANN-BERNAYS-GÖDEL SET THEORY, ZERMELO-FRAENKEL AXIOMS, ZERMELO SET THEORY

Zermelo's Axiom of Choice

AXIOM OF CHOICE

Zernike Polynomial

ORTHOGONAL POLYNOMIALS which arise in the expansion of a wavefront function for optical systems with circular pupils. The ODD and EVEN Zernike polynomials are given by

$$\begin{matrix} {}^{o}U_n^m(\rho, \phi) \\ {}^{e}U_n^m(\rho, \phi) \end{matrix} = R_n^m(\rho) \begin{matrix} \sin \\ \cos \end{matrix}(m\phi) \tag{1}$$

with radial function

$$R_n^m(\rho) = \sum_{l=0}^{(n-m)/2} \frac{(-1)^l (n-l)!}{l! \left[\tfrac{1}{2}(n+m) - l\right]! \left[\tfrac{1}{2}(n-m) - l\right]!} \rho^{n-2l} \tag{2}$$

for n and m integers with $n \geq m \geq 0$ and $n - m$ EVEN. Otherwise,

$$R_n^m(\rho) = 0. \tag{3}$$

Here, ϕ is the azimuthal angle with $0 \leq \phi < 2\pi$ and ρ is the radial distance with $0 \leq \rho \leq 1$ (Prata and Rusch 1989). The radial functions satisfy the orthogonality relation

$$\int_0^1 R_n^m(\rho) R_{n'}^m(\rho) \rho \, d\rho = \frac{1}{2(n+1)} \delta_{nn'}, \tag{4}$$

where δ_{ij} is the KRONECKER DELTA, and are related to the BESSEL FUNCTION OF THE FIRST KIND by

$$\int_0^1 R_n^m(\rho) J_m(v\rho) \rho \, d\rho = (-1)^{(n-m)/2} \frac{J_{n+1}(v)}{v} \tag{5}$$

(Born and Wolf 1989, p. 466). The radial Zernike polynomials have the GENERATING FUNCTION

$$\frac{\left[1 + z - \sqrt{1 - 2z(1 - 2\rho^2) + z^2}\right]^m}{(2z\rho)^m \sqrt{1 - 2z(1 - 2\rho^2) + z^2}} = \sum_{s=0}^{\infty} z^s R_{m+2s}^{\pm m}(\rho), \tag{6}$$

and are normalized so that

$$R_n^{\pm m}(1) = 1 \tag{7}$$

(Born and Wolf 1989, p. 465). The first few NONZERO radial polynomials are

$$R_0^0(\rho) = 1$$
$$R_1^1(\rho) = \rho$$
$$R_2^0(\rho) = 2\rho^2 - 1$$
$$R_2^2(\rho) = \rho^2$$
$$R_3^1(\rho) = 3\rho^3 - 2\rho$$
$$R_3^3(\rho) = \rho^3$$
$$R_4^0(\rho) = 6\rho^4 - 6\rho^2 + 1$$
$$R_4^2(\rho) = 4\rho^4 - 3\rho^2$$
$$R_4^4(\rho) = \rho^4$$

(Born and Wolf 1989, p. 465).

The Zernike polynomial is a special case of the JACOBI POLYNOMIAL with

$$P_{n'}^{(\alpha, \beta)}(x) = (-1)^{n'} \frac{R_n^m(\rho)}{\rho^\alpha} \tag{8}$$

and

$$x = 1 - 2\rho^2 \tag{9}$$
$$\beta = 0 \tag{10}$$
$$\alpha = m \tag{11}$$
$$n' = \tfrac{1}{2}(n - m). \tag{12}$$

The Zernike polynomials also satisfy the RECURRENCE RELATIONS

$$\rho R_n^m(\rho) = \frac{1}{2(n+1)} \times \left[(n+m+2)R_{n+1}^{m+1}(\rho) + (n-m)R_{n-1}^{m-1}(\rho)\right] \tag{13}$$

$$R_{n+2}^m(\rho) = \frac{n+2}{(n+2)^2 - m^2}\left\{\left[4(n+1)\rho^2 - \frac{(n+m)^2}{n} - \frac{(n-m+2)^2}{n+2}\right]R_n^m(\rho) - \frac{n^2-m^2}{n} R_{n-2}^m(\rho)\right. \tag{14}$$

$$R_n^m(\rho) + R_n^{m+2}(\rho) = \frac{1}{n+1}\frac{d\left[R_{n+1}^{m+1}(\rho) - R_{n-1}^{m+1}(\rho)\right]}{d\rho} \tag{15}$$

(Prata and Rusch 1989). The coefficients A_n^m and B_n^m in the expansion of an arbitrary radial function $F(\rho, \phi)$ in terms of Zernike polynomials

$$F(\rho, \phi) = \sum_{m=0}^{\infty}\sum_{n=m}^{\infty}[A_n^m {}^oU_n^m(\rho, \phi) + B_n^m {}^eU_n^m(\rho, \phi)] \tag{16}$$

are given by

$$\begin{matrix} A_n^m \\ B_n^m \end{matrix} = \frac{(n+1)}{\epsilon_{mn}^2 \pi}\int_0^1\int_0^{2\pi} F(\rho, \phi) \begin{matrix} {}^oU_n^m(\rho, \phi) \\ {}_eU_n^m(\rho, \phi) \end{matrix} \rho\, d\phi\, d\rho, \tag{17}$$

where

$$\epsilon_{mn} \equiv \begin{cases} \epsilon \equiv \frac{1}{\sqrt{2}} & \text{for } m=0,\ n \neq 0 \\ 1 & \text{otherwise} \end{cases} \tag{18}$$

Let a "primary" aberration be given by

$$\Phi = a'_{lmn}\bar{Y}_1^{2l+m}(\theta, \phi)\rho^n \cos^m \theta \tag{19}$$

with $2l+m+n=4$ and where $\bar{Y}$ is the COMPLEX CONJUGATE of Y, and define

$$A'_{lmn} = a'_{lmn}\bar{Y}_1^{2l+m}(\theta, \phi), \tag{20}$$

giving

$$\Phi = \frac{1}{\epsilon_{nm}^2} A_{lmn}R_n^m(\rho)\cos(m\theta). \tag{21}$$

Then the types of primary aberrations are given in the following table (Born and Wolf 1989, p. 470).

Aberration	l	m	n	A	A'
spherical aberration	0	4	0	$A'_{040}\rho^4$	$\epsilon A_{040}R_4^0(\rho)$
coma	0	3	1	$A'_{031}\rho^3 \cos\theta$	$A_{031}R_3^1(\rho)\cos\theta$
astigmatism	0	2	2	$A'_{022}\rho^2\cos^2\theta$	$A_{022}R_2^2(\rho)\cos(2\theta)$
field curvature	1	2	0	$A'_{120}\rho^2$	$\epsilon A_{120}R_2^0\rho$
distortion	1	1	1	$A'_{111}\rho\cos\theta$	$A_{111}R_1^1(\rho)\cos\theta$

Zero

The INTEGER denoted 0 which, when used as a counting number, means that no objects are present. It is the only INTEGER (and, in fact, the only REAL NUMBER) which is neither NEGATIVE nor POSITIVE. A number which is not zero is said to be NONZERO. A ROOT of a function f is also sometimes known as "a zero of f."

Because the number of PERMUTATIONS of 0 elements is 1, 0! (zero FACTORIAL) is defined as 1 (Wells 1986, p. 31). This definition is useful in expressing many mathematical identities in simple form. A number *other than 0* taken to the POWER 0 is defined to be 1, but 0^0 is undefined. Defining $0^0=1$ allows some formulas to be expressed simply (Knuth 1997, p. 56), although the same could be said for the alternate definition $0^0=0$ (Wells 1986, p. 26). An example of a formula which can be expressed concisely by defining $0^0=1$ is the beautiful analytical formula for the integral of the generalized SINC FUNCTION

$$\int_0^\infty \frac{\sin^a x}{x^b}\,dx = \frac{\pi^{1-c}(-1)^{\lfloor (a-b)/2\rfloor}}{2^{a-c}(b-1)!}$$

$$\times \sum_{k=0}^{\lfloor a/2 \rfloor - c} (-1)^k \binom{a}{k} (a-2k)^{b-1} [\ln(a-2k)]c$$

given by Kogan, where $a \geq b > c$, $c \equiv a - b \pmod 2$, and $\lfloor x \rfloor$ is the FLOOR FUNCTION.

The following table gives the first few numbers n such that the decimal expansion of k^n contains no zeros, for small k. The largest known n for which 2^n contain no zeros is 86 (Madachy 1979), with no other $n \leq 4.6 \times 10^7$ (M. Cook), improving the 3.0739×10^7 limit obtained by Beeler and Gosper (1972). The values $a(n)$ such that the positions of the right-most zero in $2^{a(n)}$ increases are 10, 20, 30, 40, 46, 68, 93, 95, 129, 176, 229, 700, 1757, 1958, 7931, 57356, 269518, ... (Sloane's A031140). The positions in which the right-most zeros occur are 2, 5, 8, 11, 12, 13, 14, 23, 36, 38, 54, 57, 59, 93, 115, 119, 120, 121, 136, 138, 164, ... (Sloane's A031141). The right-most zero of $2^{781,717,865}$ occurs at the 217th decimal place, the farthest over for powers up to 2.5×10^9.

k	Sloane	n such that k^n contains no 0s
2	Sloane's A007377	1, 2, 3, 4, 5, 6, 7, 8, 9, 13, 14, 15, 16, 18, 19, 24, 25, 27, 28, ...
3	Sloane's A030700	1, 2, 3, 4, 5, 6, 7, 8, 9, 11, 12, 13, 14, 19, 23, 24, 26, 27, 28, ...
4	Sloane's A030701	1, 2, 3, 4, 7, 8, 9, 12, 14, 16, 17, 18, 36, 38, 43, ...
5	Sloane's A008839	1, 2, 3, 4, 5, 6, 7, 9, 10, 11, 17, 18, 30, 33, 58, ...
6	Sloane's A030702	1, 2, 3, 4, 5, 6, 7, 8, 12, 17, 24, 29, 44, ...
7	Sloane's A030703	1, 2, 3, 6, 7, 10, 11, 19, 35
8	Sloane's A030704	1, 2, 3, 5, 6, 8, 9, 11, 12, 13, 17, 24, 27
9	Sloane's A030705	1, 2, 3, 4, 6, 7, 12, 13, 14, 17, 34
11	Sloane's A030706	1, 2, 3, 4, 6, 7, 8, 9, 12, 13, 14, 15, 16, 18, 41, ...

While it has not been proven that the numbers listed above are the only ones without zeros for a given base, the probability that any additional ones exist is vanishingly small. Under this assumption, the sequence of largest n such that k^n contains no zeros for $k = 2, 3, ...$ is then given by 86, 68, 43, 58, 44, 35, 27, 34, 0, 41, ... (Sloane's A020665).

Zero (Root)

ROOT

Zero Divisor

A NONZERO element x of a RING for which $x \cdot y = 0$, where y is some other NONZERO element and the multiplication $x \cdot y$ is the multiplication of the RING. A RING with no zero divisors is known as an INTEGRAL DOMAIN. Let A denote an $\mathbb{R}$-algebra, so that A is a VECTOR SPACE over R and

$$A \times A \to A$$

$$(x, y) \mapsto x \cdot y.$$

Now define

$$Z \equiv \{x \in A : x \cdot y = 0 \text{ for some nonzero } y \in A\},$$

where $0 \in Z$. A is said to be m-ASSOCIATIVE if there exists an m-dimensional SUBSPACE S of A such that $(y \cdot x) \cdot z = y \cdot (x \cdot z)$ for all $y, z \in A$ and $x \in S$. A is said to be TAME if Z is a finite union of SUBSPACES of A.

Zero Irrelevancy Proof

CLASSIFICATION THEOREM OF SURFACES

Zero Map

See also IDENTITY MAP

Zero Matrix

A MATRIX consisting of all 0s, denoted 0. The MATRIX EXPONENTIAL of 0 is given by the IDENTITY MATRIX I. An $m \times n$ zero matrix can be generated using `ZeroMatrix[m, n]` in the *Mathematica* add-on package `LinearAlgebra'MatrixMultiplication'`

(which can be loaded with the command `<<LinearAlgebra‘`).

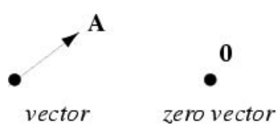
See also IDENTITY MATRIX

Zero Section

This entry contributed by RYAN BUDNEY

The zero section of a VECTOR BUNDLE is the SUBMANIFOLD of the bundle that consists of all the ZERO VECTORS.

See also BUNDLE, MANIFOLD, SECTION (BUNDLE), VECTOR BUNDLE, ZERO VECTOR



Zero Set

If f is a function on an OPEN SET U, then the zero set of f is the set $Z=\{z\in U: f(z)=0\}$.

References

Krantz, S. G. *Handbook of Complex Analysis.* Boston, MA: Birkhäuser, p. 268, 1999.

Zero Vector

A ZERO VECTOR, denoted $\mathbf{0}$, is a VECTOR of length 0, and thus has all components equal to zero.

See also UNIT VECTOR, ZERO VECTOR

Zero-Form

See also DIFFERENTIAL k-FORM, ONE-FORM, TWO-FORM

Zerofree

An integer whose decimal digits contain no zeros is said to be zerofree. Zerofree squares are easy to generate, e.g.,

$$3333333333333334^2 = 11111111111111115555555555555556. \quad (1)$$

Around 1990, D. Hickerson considered the problem of finding large zerofree cubes. After some experimentation, he found a formula that generated infinitely many of them. In March 1998, Bill Gosper asked about 0-free nth powers, pointing out that heuristically we should expect there to be infinitely many zerofree squares, cubes, ..., 21st powers, but only finitely many 22nd powers, etc. At this point, Hickerson couldn't locate his formula for cubes, and so came up with the new formula

$$f(n)=\frac{2\cdot 10^{5n}-10^{4n}+17\cdot 10^{3n-1}+10^{2n}+10^{n-2}}{3}, \quad (2)$$

which is 0-free if $n\equiv 2 \pmod 3$ and $n\geq 5$.

In April 1999, Ed Pegg conjectured on `sci.math` that there are only finitely many zerofree cubes, so Hickerson posted his new counterexample, (mistakenly claiming that it was the one he had found 10 years ago). A few days later, Lew Baxter posted the slightly simpler example

$$f(n)=\tfrac{1}{3}(2\cdot 10^{5n}-10^{4n}+2\cdot 10^{3n}+10^{2n}+10^{n}+1), \quad (3)$$

known as the BAXTER-HICKERSON FUNCTION.

There is apparently no proof that there exist infinitely many zerofree 4th powers, 5th powers, ..., or 21st powers.

See also BAXTER-HICKERSON FUNCTION, ZERO

Zero-Sum Game

A GAME in which players make payments only to each other. One player's loss is the other player's gain, so the total amount of "money" available remains constant.

See also FINITE GAME, GAME

Zeta

HURWITZ ZETA FUNCTION, RIEMANN ZETA FUNCTION

Zeta Fuchsian

The zeta Fuchsians are class of functions discovered by Poincaré which are related to the AUTOMORPHIC FUNCTIONS.

See also AUTOMORPHIC FUNCTION

Zeta Function

A function satisfying certain properties which is computed as an INFINITE SUM of NEGATIVE POWERS. The most commonly encountered zeta function is the RIEMANN ZETA FUNCTION,

$$\zeta(n)\equiv\sum_{k=1}^{\infty}\frac{1}{k^n}.$$

See also DEDEKIND FUNCTION, DIRICHLET BETA FUNCTION, DIRICHLET ETA FUNCTION, DIRICHLET L-SERIES, DIRICHLET LAMBDA FUNCTION, EPSTEIN ZETA FUNCTION, JACOBI ZETA FUNCTION, NINT ZETA FUNC-

TION, PERIODIC ZETA FUNCTION, PRIME ZETA FUNCTION, RIEMANN ZETA FUNCTION, SELBERG ZETA FUNCTION

Zeuthen's Rule

On an ALGEBRAIC CURVE, the sum of the number of coincidences at a noncuspidal point C is the sum of the orders of the infinitesimal distances from a nearby point P to the corresponding points when the distance PC is taken as the principal infinitesimal.

References

Coolidge, J. L. *A Treatise on Algebraic Plane Curves.* New York: Dover, p. 131, 1959.

Zeuthen's Theorem

If there is a (v, v') correspondence between two curves of GENUS p and p' and the number of BRANCH POINTS properly counted are β and β', then

$$\beta + 2v'(p-1) = \beta' + 2v(p'-1).$$

Zig Number

An ODD ALTERNATING PERMUTATION number, more commonly called an EULER NUMBER or SECANT NUMBER.

See also ALTERNATING PERMUTATION, EULER NUMBER, ZAG NUMBER

Zigzag Permutation

ALTERNATING PERMUTATION

Zig-Zag Triangle

SEIDEL-ENTRINGER-ARNOLD TRIANGLE

Zillion

A generic word for a very LARGE NUMBER. The term has no WELL DEFINED mathematical meaning. Conway and Guy (1996) define the nth zillion as 10^{3n+3} in the American system (million $= 10^6$, billion $= 10^9$, trillion $= 10^{12}$, $\ldots$), and 10^{6n} in the British system (million $= 10^6$, billion $= 10^{12}$, trillion $= 10^{18}$, $\ldots$), Conway and Guy (1996) also define the words N-PLEX and N-MINEX for 10^n and 10^{-n}, respectively.

See also LARGE NUMBER

Zip

Half a ZIP-PAIR.

ZIP Proof

CLASSIFICATION THEOREM OF SURFACES

Zipf's Law

In the English language, the probability of encountering the rth most common word is given roughly by $P(r) = 0.1/r$ for r up to 1000 or so. The law breaks down for less frequent words, since the HARMONIC SERIES diverges. Pierce's (1980, p. 87) statement that $\Sigma\, P(r) > 1$ for $r = 8727$ is incorrect. Goetz states the law as follows: The frequency of a word is inversely proportional to its RANK r such that

$$P(r) \approx \frac{1}{r \ln(1.78R)},$$

where R is the number of different words.

See also HARMONIC SERIES, RANK (STATISTICS)

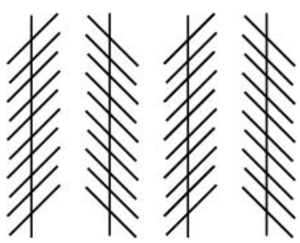
Z-Number

A Z-number is a REAL NUMBER ζ such that

$$0 \leq \text{frac}\left[\left(\frac{3}{2}\right)^k \zeta\right] < \tfrac{1}{2}$$



for all $k = 1, 2, ...$, where frac(x) is the fractional part of x. Mahler (1968) showed that there is at most one Z-number in each interval $[n, n+1)$ for integer n, and therefore concluded that it is unlikely that any Z-numbers exist. The Z-numbers arise in the analysis of the COLLATZ PROBLEM.

See also COLLATZ PROBLEM

Zome

A kit consisting of rods and slotted balls that can be used to construct three-dimensional configurations. The balls into which the rods are placed resembles an "expanded" SMALL RHOMBICOSIDODECAHEDRON, with the squares replaced by rectangles, as illustrated above. The rods come in four colors, and there are three lengths for each color, as summarized in the table below. Here, ϕ is the GOLDEN RATIO.

color	lengths	n
blue	ϕ^n	$n = 0, 1, 2$
yellow	$\cos\left(\frac{1}{6}\pi\right)\phi^n$	$n = 0, 1, 2$
red	$\cos\left(\frac{1}{10}\pi\right)\phi^n$	$n = 0, 1, 2$
green	$\cos\left(\frac{1}{4}\pi\right)\phi^n$	$n = -1, 0, 1$

Zonal Harmonic

A SPHERICAL HARMONIC OF THE FORM $P_l(\cos\theta)$, i.e., one which reduces to a LEGENDRE POLYNOMIAL (Whittaker and Watson 1990, p. 302). These harmonics are termed "zonal" since the curves on a UNIT SPHERE (with center at the origin) on which $P_l(\cos\theta)$ vanishes are l parallels of latitude which divide the surface into zones (Whittaker and Watson 1990, p. 392).

Resolving $P_l(\cos\theta)$ into factors linear in $(\cos^2\theta)$, multiplied by $(\cos\theta)$ when l is ODD, then replacing $(\cos\theta)$ by z/r allows the zonal harmonic $r^l P_l(\cos\theta)$ to be expressed as a product of factors linear in x^2, y^2, and z^2, with the product multiplied by z when n is ODD (Whittaker and Watson 1990, p. 1990).

Zone

The SURFACE AREA of a SPHERICAL SEGMENT. Call the RADIUS of the SPHERE R, the upper and lower RADII b and a, respectively, and the height of the SPHERICAL SEGMENT h. The zone is a SURFACE OF REVOLUTION about the z-AXIS, so the SURFACE AREA is given by

$$S = 2\pi \int x\sqrt{1+x'^2}\, dz. \quad (1)$$

In the xz-plane, the equation of the zone is simply that of a CIRCLE,

$$x = \sqrt{R^2 - z^2}, \quad (2)$$

so

$$x' = -z(R^2 - z^2)^{-1/2} \quad (3)$$

$$x'^2 = \frac{z^2}{R^2 - z^2}, \quad (4)$$

and

$$S = 2\pi \int_{\sqrt{R^2-a^2}}^{\sqrt{R^2-b^2}} \sqrt{R^2 - z^2}\sqrt{1 + \frac{z^2}{R^2 - z^2}}\, dz$$

$$= 2\pi R \int_{\sqrt{R^2-a^2}}^{\sqrt{R^2-b^2}} dz = 2\pi R\left(\sqrt{R^2 - b^2} - \sqrt{R^2 - a^2}\right)$$

$$= 2\pi R h. \quad (5)$$

This result is somewhat surprising since it depends only on the *height* of the zone, not its vertical position with respect to the SPHERE.

Zonohedron

A CONVEX POLYHEDRON whose faces all possess a central symmetry (Coxeter 1973, pp. 27–30). Equivalently, a convex polyhedron whose faces are PARALLEL-sided $2m$-gons.

There exist $n(n-1)$ PARALLELOGRAMS in a nonsingular zonohedron, where n is the number of different directions in which EDGES occur (Ball and Coxeter 1987, pp. 141–144). Zonohedra include the CUBE, ENNEACONTAHEDRON, GREAT RHOMBIC TRIACONTAHEDRON, GREAT RHOMBICUBOCTAHEDRON, MEDIAL RHOMBIC TRIACONTAHEDRON, RHOMBIC DODECAHEDRON, RHOMBIC ICOSAHEDRON, RHOMBIC TRIACONTAHEDRON, and RHOMBOHEDRON, as well as the entire class of PARALLELEPIPEDS.

Regular zonohedra have bands of PARALLELOGRAMS which form equators and are called "ZONES." Every convex polyhedron bounded solely by PARALLELOGRAMS is a zonohedron (Coxeter 1973, p. 27). Plate II (following p. 32 of Coxeter 1973) illustrates some equilateral zonohedra. Equilateral zonohedra can be regarded as 3-dimensional projections of n-D HYPERCUBES (Ball and Coxeter 1987).

Zorn's Lemma

If S is any nonempty PARTIALLY ORDERED SET in which every CHAIN has an upper bound, then S has a maximal element. This statement is equivalent to the AXIOM OF CHOICE.

See also AXIOM OF CHOICE

z-Score

The z-score associated with the ith observation of a random variable x is given by

$$z_i \equiv \frac{x_i - \bar{x}}{\sigma},$$

where $\bar{x}$ is the MEAN and σ the STANDARD DEVIATION of all observations x_1, ..., x_n.

Zsigmondy Theorem

If $1 \leq b < a$ and $(a, b) = 1$ (i.e., a and b are RELATIVELY PRIME), then $a^n - b^n$ has a PRIMITIVE PRIME FACTOR with the following two possible exceptions:

1. $2^6 - 1^6$.
2. $n = 2$ and $a + b$ is a POWER of 2.

Similarly, if $a > b \geq 1$, then $a^n + b^n$ has a PRIMITIVE PRIME FACTOR with the exception $2^3 + 1^3 = 9$.

References

Ribenboim, P. *The Little Book of Big Primes.* New York: Springer-Verlag, p. 27, 1991.

Z-Transform

The Z-transform of $F(t)$ is defined by

$$Z[F(t)] = \mathscr{L}[F^*(t)], \tag{1}$$

where

$$F^*(t) = F(t)\delta_T(t) = \sum_{n=0}^{\infty} F(nT)\delta(t-nT), \tag{2}$$

$\delta(t)$ is the DELTA FUNCTION, T is the sampling period, and $\mathscr{L}[f]$ is the LAPLACE TRANSFORM. An alternative definition is

$$Z[F(t)] = \sum_{\text{residues}} \left(\frac{1}{1-e^{T_z}z^{-1}}\right) f(z), \tag{3}$$

where

$$f(z) = \sum_{n=0}^{\infty} F(nT)z^{-n}. \tag{4}$$

The inverse Z-transform is

$$Z^{-1}[f(z)] = F^*(t) = \frac{1}{2\pi i}\oint f(z)z^{n-1}\,dz. \tag{5}$$

The GENERATING FUNCTION of $G(t)$ of a sequence of numbers $f(n)$ given by the Z-transform of $f(n)$ in the variable $1/t$ (Germundsson 2000).

It satisfies

$$Z[aF(t)+bG(t)] = aZ[F(t)]+bZ[F(t)] \tag{6}$$

$$Z[F(t+T)] = zZ[F(t)]-zF(0) \tag{7}$$

$$Z[F(t+2T)] = z^2Z[F(t)]-z^2F(0)-zF(t) \tag{8}$$

$$Z[F(t+mT)] = z^mZ[F(t)]-\sum_{r=0}^{m-1} z^{m-r}F(rt) \tag{9}$$

$$Z[F(t-mT)] = z^{-m}Z[F(t)] \tag{10}$$

$$Z[e^{at}F(t)] = Z\left[e^{-aT}z\right] \tag{11}$$

$$Z[e^{-at}F(t)] = Z\left[e^{aT}z\right] \tag{12}$$

$$tF(t) = -Tz\frac{d}{dz}Z[F(t)] \tag{13}$$

$$t^{-1}F(t) = -\frac{1}{T}\int_0^z \frac{f(z)}{z}\,dz. \tag{14}$$

Transforms of special functions (Beyer 1987, pp. 426–427) include

$$Z[\delta(t)] = 1 \tag{15}$$

$$Z[\delta(t-mT)] = z^{-m} \tag{16}$$

$$Z[H(t)] = \frac{z}{z-1} \tag{17}$$

$$Z[H(t-mT)] = \frac{z}{z^m(z-1)} \tag{18}$$

$$Z[t] = \frac{Tz}{(z-1)^2} \tag{19}$$

$$Z\left[t^2\right] = \frac{T^2z(z+1)}{(z-1)^3} \tag{20}$$

$$Z\left[t^3\right] = \frac{T^3z(z^2+4z+1)}{(z-1)^4} \tag{21}$$

$$Z[a^{\omega t}] = \frac{z}{z - a^{\omega T}} \tag{22}$$

$$Z[\cos(\omega t)] = \frac{z \sin(\omega T)}{z^2 - 2z \cos(\omega T) + 1} \tag{23}$$

$$Z[\sin(\omega t)] = \frac{z[z - \cos(\omega T)]}{Z^2 - 2z \cos(\omega T) + 1}, \tag{24}$$

where $H(t)$ is the HEAVISIDE STEP FUNCTION.

In general,

$$Z[t^n] = (-1)^n \lim_{x \to 0} \frac{\delta^n}{\delta x^n} \left(\frac{z}{z - e^{-xT}} \right) \tag{25}$$

$$\frac{T^n z \sum_{k=1}^{n} \left\langle {n \atop k} \right\rangle z^{k-1}}{(z-1)^{n+1}}, \tag{26}$$

where the $\left\langle {n \atop k} \right\rangle$ are EULERIAN NUMBERS. Amazingly, the Z-transforms of t^n are therefore generators for EULER'S TRIANGLE.

The discrete z-transform of a sequence $\{a_j\}_{j=-\infty}^{\infty}$ is defined as

$$A(z) = Z[a] = \sum_{k=-\infty}^{\infty} a_k z^{-k} \tag{27}$$

(Krantz 1999, p. 214). The DISCRETE FOURIER TRANSFORM is therefore a special case of the z-transform with

$$z \equiv e^{-2\pi i/N}. \tag{28}$$

A z-transform with

$$z \equiv e^{-2\pi i \alpha/N} \tag{29}$$

for $\alpha \neq \pm 1$ is called a FRACTIONAL FOURIER TRANSFORM.

See also DISCRETE FOURIER TRANSFORM, EULER'S TRIANGLE, EULERIAN NUMBER, FRACTIONAL FOURIER TRANSFORM
